GRETRY.

GRETRY, ANDRE, in *Biography*, a fertile and pleaſing compoſer of comic operas, in the French language, was born at Leige in 1741. At ſix or ſeven years old he became a choriſter in that cathedral; but was extremely ill-treated by a brutal ſinging maſter; by whom he was ſent home, in a bad ſtate of health. During his convaleſcence, he hears with rapture ſome Italians ſing at the theatre; has the liberty of the orcheſtra granted him, by which he improves ſo much, that at his return to the choir he gains great credit in the performance of a motet, or anthem, and continued making a rapid progreſs in ſinging till his voice broke. But while it was ſinking, in order to pleaſe his admirers and gratify vanity, in ſinging an air by Galuppi, (at a concert,) that was very high, he brought on a hemorrhage, and continued ſpitting blood for a long time after. He relates the remedies that were moſt efficacious in alleviating his complaint, but which was never quite cured.

Upon the total loſs of his voice, and the precarious ſtate of his health, he began to ſtudy compoſition, but without a maſter, and without rules; and having heard that it was difficult to compoſe fugues, he began a fugue in four parts; reverſed the ſubject; and afterwards compoſed a full anthem of ſhreds and patches from other full anthems, without inventing a ſingle bar: the common practice, we believe, of all beginners who teach themſelves. At length, he had a regular and indulgent maſter in counterpoint during two years; and with pleaſure dived into thoſe myſteries which terrify timid ſtudents under ſevere maſters. M. Rincken, a celebrated organiſt of St. Peter's church at Leige, was his inſtructor; who began by teaching him the common chord and its inverſions; the chord of the 7th to the 6th of the key, and then the *regle de l'octave*. Theſe were acquired in two months time. He afterwards gave him examples, in a figured baſe, of exceptions, eight rules for the uſe of diſcords derived from the 7th, in a MS. of which he has long lamented the loſs. His maſter ſtopped him on the chord of the extreme flat 7th, to ſhew him that any one note of that chord might be made the 7th of another key. (See ENHARMONIC *chord*.) Here follows an eloge of his maſter's kindneſs, candour, and enthuſiaſtic intereſt which he took in his improvement during two years. He recommends to all maſters the acquiring, if poſſible, the love of their pupils, which will not only render their inſtructions impreſſive but delightful. And without the talent of attaching the ſcholar, and making him love his buſineſs and his maſter, all the reſt is uſeleſs. Gretry grew paſſionately fond of his ſtudies, as much to pleaſe his maſter as improve himſelf. On carrying to a new maſter a maſs which he had juſt compoſed.—"Fair and ſoftly!" ſays M. Moreau; "you run too faſt." Returning the young compoſer his ſcore without looking at it; he wrote down on a ſlip of paper five or ſix ſemibreves. "Write," ſays he, "a treble to this baſe, and ſhew it me to-morrow; but, above all, attempt no more maſſes." "I went from him a little humbled, ſaying to myſelf, my father was in the right in thinking my firſt maſter too indulgent. I carried him his baſe the next day, ornamented with three or four trebles."—"You ſtill march too faſt," he cries; "I only aſked for note againſt note to this baſe."—"I could not reſtrain my impetuoſity. I had a thouſand muſical ideas in my head, and was eager to make uſe of them." "*Dominus vobiſcum*, in contrary motion," ſays my maſter, "that's the way the different parts ſhould move."—"I

Strahan and Preſton,
New-Street-Square, London.

quitted him, ſaying to myſelf, I have learned nothing by theſe two leſſons; but let us go on fair and ſoftly. Yet I could not help ſcribbling. I compoſed ſix ſymphonies, which were ſucceſsfully executed in our city. M. Haſler, the canon, begged me to let him carry them to the concert. He encouraged me greatly; adviſed me to go to Rome, in order to purſue my ſtudies, and offered me his purſe. My maſter in compoſition thought this little ſucceſs would be miſchievous to me, and prevent me from purſuing that regular courſe of ſtudy, ſo neceſſary to the becoming a ſound contrapuntiſt. He never mentioned my ſymphonies." The author, however, does not pretend that the ſame method will do for all ſtudents: the leſſons ſhould be proportioned to the genius and diligence of the ſcholar.

The plan of going to Rome to purſue his ſtudies never quitted the young Gretry. He finiſhed his maſs, and ſhewed it to M. Moreau: telling him, that he agreed in his opinion, that a young muſician, ignorant as himſelf, ought never to attempt ſuch conſiderable works.

He walked to Rome on foot, at eighteen years of age, where he remained five years; during which time he was received into the college of Leige, and lodged and boarded at the expence of that eſtabliſhment. See LEIGE.

Of all that concerns his private life, ſocial intercourſe, maſters, and ſtudies at Rome, we ſhall confine our obſervations, as much as poſſible, to ſuch circumſtances and reflections as may be uſeful to muſical ſtudents, who are likely to ſeek for profeſſional knowledge from books.

On his arrival in Italy, after croſſing the Alps, his reflections are animated, and do juſtice to that country and his own feelings.

"After we had penetrated a little way into the mountains, rocks, and glaciers; nature ſeems ſuddenly to have changed her face. With what pleaſure did I find myſelf all at once in a field enamelled with flowers! It ſeemed as if ſome good genius had tranſported us from earth to heaven. I begged our guide to let me ſtop a moment to enjoy this delicious proſpect; but what was my rapture when I heard, for the firſt time, Italian melody ſung by an Italian! It was from a charming female voice, which tranſported me by its melodious accents. This was the firſt leſſon which I received in muſic, in a country to which I had travelled for inſtruction.

"And this touching voice, with that plaintive expreſſion, which an almoſt vertical ſun generally inſpires; in ſhort, thoſe delicious and exquiſite ſenſations, which I ſought at ſuch a diſtance from my native ſoil, and for which I had quitted every thing, were found in a ſimple country girl."

The maſters in the Roman churches, during his reſidence in that renowned city, were Caſali, Oriſicchio, and the abate Luſtrini, whom he has well characterized. Caſali had grace and facility; Oriſicchio more ſtudy and correctneſs in his counterpoint; and Luſtrini, his diſciple, had the merit of preſerving the auſterity and dignity of the eccleſiaſtical ſtyle, which ought never to be abandoned; but a compoſer thinks it neceſſary to try to pleaſe, even in the church: a rapturous rumour is heard when a movement pleaſes; this induces the chapel-maſter to quit the gravity which the place of performance requires, and they finiſh by confounding the muſic of the church with that of the theatre.

At the end of the reign of Benedict XIV. this abuſe was carried ſo far, that the pope ordered the ſacrament to be adminiſtered in the ſide chapels, to prevent the Romans from attending more to the muſicians than the prieſts, and turning their backs upon the altar. He prohibited the uſe of kettle-drums, trumpets, and all noiſy wind-inſtruments, commanding the maeſtro di cappella, under ſevere penalties, to finiſh the veſpers by day light.

When this part of the author's book was written, he ſeems to have been untainted with philoſophiſm, and to have reſpected the church, concerning the muſic of which he gives ſome admirable counſel to young compoſers.

The maſters of Italy, particularly of the Neapolitan ſchool, begin with church muſic, and the maſter-pieces of Aleſſ. Scarlatti, Durante, Leo, Pergoleſi, Piccini, and Sacchini, which are their maſſes, and are compoſed in a ſtyle of muſic which ſhould be totally diſtinct from that of the theatre.

In church muſic a compoſer may ſtill with propriety avail himſelf of all the riches of learned counterpoint, of canons and fugues, which the theatre but rarely admits.

Secular compoſers may ſometimes, without impropriety and with great effect, write in imitation of the church ſtyle; they riſk nothing in ennobling paſſions connected with the good order and happineſs of mankind.

Eccleſiaſtical muſic is degraded if it quits the bounds preſcribed to it by piety and propriety, while dramatic muſic is exalted by the occaſional admiſſion of ſolemn ſtrains.

The ſtudy of the ideal beauties of harmony is the principal buſineſs of a compoſer of ſacred muſic. M. Gretry calls learned muſic the metaphyſical language of ſound. In a theatre the expreſſion of the words and ſituation of the ſinger muſt be exact, becauſe they have a determined ſenſe, and the true expreſſion of the words fortifies the ſituation through all the accompaniments.

He thinks a dull man, if a good harmoniſt, may write good church muſic; but we find a charm in the moſt ſolemn and ſeemingly dry choral compoſitions of Paleſtrina, Coſtantio, Feſta, Leo, Jomelli, Pergoleſi, and Sacchini, apart from the learning and gravity of their ſtyle.

He does not allow that any muſician plays or performs muſic perfectly at ſight, that is not very eaſy and very common, which is the ſame thing; and, in general, what is meant by *natural muſic*. A muſician, to prove himſelf a good ſightſman, muſt ſatisfy the author himſelf, not only by performing the notes correctly, but by ſeizing the true expreſſion, and not auditors ignorant of the compoſer's deſign, and who think it well executed becauſe it is done without heſitation.

At Geneva the father of a child, who paſſed for a *prodigy*, in playing at ſight, deſired M. Gretry to compoſe a very difficult ſonata expreſsly to try his powers of execution, *a' livre ouvent*, and he made an allegro for him, difficult, but without affectation; which the child executed to the aſtoniſhment of every hearer but Gretry himſelf. The young performer did not ſtop or flounder, but in following the modulations, he changed many paſſages which the compoſer had written, without ſhocking the ear.

"When a ſtudent changes his maſter, he ſhould recommence the firſt principles of compoſition, or the maſter and ſcholar will perpetually miſtake each other's meaning."

Caſali conducted him from fugue to fugue in 2, 3, and 4 parts, adviſing him not to indulge himſelf in compoſitions of a leſs ſevere kind. This was the method which P. Martini purſued with all his diſciples, in proportion to their advancement in the art.

He complains of the cold reception he had from Piccini, when introduced to him as a promiſing young artiſt. Piccini had always a cold and diſcouraging countenance, and was at all times profeſſionally ſo much occupied, that he had no time to ſacrifice to viſitors and politeneſs.

After our author began to write good fugues in four parts,

parts, Caſali adviſed him to compoſe motets or full anthems, in 6 or 8 parts, as the *ne plus ultra* of compoſition. After cloſe application under Caſali, during two years, this honourable and able maſter told him he might proceed without a guide.

When he quitted Rome he went to Bologna, where he was received a member of the Philharmonic ſociety, for the obtaining which honour the good Padre Martini aided and aſſiſted him with his counſel in writing a fugue on a fragment of canto fermo, taken by chance.

He was now left to himſelf with his head full of fugues and canons of all kinds, which he could turn topſy-turvy, and of which he could reverſe all the parts at his pleaſure, ſtill preſerving a kind of melody in them all, "and I am certain (he ſays) that a compoſer cannot be ſimple and expreſſive, and, leaſt of all, correct, without vanquiſhing all the difficulties of counterpoint."

A profound contrapuntiſt diſcovers in a ſcore, by a ſingle glance, whether the author is a regular bred harmoniſt; a ſingle note is ſufficient: as a ſingle bare-faced lie throws a doubt upon every thing that its author utters, and there are certain notes in a well regulated baſe, beyond the ken of a ſuperficial contrapuntiſt.

He adviſes the ſtudent to continue writing fugues a conſiderable time, in two parts, in order to familiarize himſelf with the rules for bringing in the anſwers, and ſeizing every favourable opportunity of imitating ſmall portions of the principal ſubject, and its accompaniments. He has inſerted the ſketches of an eaſy fugue, giving the ſubject alternately to the two parts in the regular modulation from key to key, without filling up the accompaniment, which is to correct the melody and complete the harmony. It would be good exerciſe if the young harmoniſt were to add a ſecond treble, a tenor, or a ſecond baſe, as a free part, before he attempts a third in fugue. And in doing this he ſhould try to find ſuch notes as will not only enrich the harmony, but form an agreeable melody in itſelf; and not be content with every unmeaning note which the harmony of the two principal parts will allow. He recommends ſix months to this ſtudy alone. A young organiſt will begin to play extempore fugues before he will be able to commit them to paper with accuracy and clearneſs.

The author tells us that though he loved the muſic of Buranello, Piccini, Sacchini, Ciecio di Majo, and Terradeglias; yet Pergoleſi was his model. We do not recollect, however, being reminded of Pergoleſi's ſtyle by any of M. Gretry's operas, though there are pleaſing airs in them all, caſt in a French mould, which the poetry and national taſte required. Neither Piccini nor Sacchini could always avoid French phraſeology in their melodies in ſetting French words. Gluck adopted the paſſages of Lulli and Rameau, to flatter the nation which he was going to amuſe; but Piccini and Sacchini *under-wrote* the airs, which they ſet to French words, from the mere want of vocal abilities on the opera ſtage of Paris to execute better. The French muſical critics, however, flatter themſelves that the worſe the airs the better the opera, and endeavour to perſuade all Europe that fine ſinging is abſurd, and ruins the drama.

In the chapter of M. Gretry's memoirs, entitled "De la Muſique d'Egliſe," in which he has given the hiſtory of his ſtudies at Rome, after quitting Caſali and going to Bologna, where he is admitted member of the Philharmonic ſociety, he goes back in his narrative to Rome, and relates in an entertaining manner the reception of his firſt comic opera, ſet to Italian words, in that city; charecterizes the muſic of Italy, by ſaying that "the Italian ſchool is the beſt that exiſts, as well for compoſition as ſinging. Italian melody is ſimple and beautiful; it is never ſuffered to be coarſe or inelegant; and a difficult paſſage is deemed barbarous that does not flow naturally from the ſubject, and without effect.

"It is generally agreed (ſays M. Gretry) that the inſtrumental muſic of Italy is feeble; but how ſhould it be otherwiſe? there is little melody, becauſe they are aiming at harmonical effects; yet little harmony is produced, as they are ignorant of modulation. It is eaſy to conceive that abſtracted from theſe two agents, nothing can remain but noiſe."

About this time the opera overtures anſwered this character; and the German ſymphonies of the Manheim ſchool began to be well performed, not only in the northern parts of Germany, but at Paris and Bruſſels. Choruſes were never laboured in Italian operas; as learned choruſes with fugues and complication, in which there is no melody in the under parts, can never be remembered or enlivened by action on the ſtage. But to ſave the Italians from the cenſures of M. Gretry on account of the poverty of their inſtrumental muſic, the Italians had at this time the admirable Boccherini, ſuperior in muſic for violins, without double drums, tromboni, and the noiſe and falſe intonation of many other wind inſtruments, not only to the reſt of his countrymen, but to all the Germanic body anterior to Haydn and Mozart.

His cenſures of the Italian opera, at a time when every part of Europe, except France, was enchanted with it, are copied from Gluck's dedication to his "Alceſte."

M. Gretry ſays (to humour the French) that a great ſinger ruins an opera, by rendering every character which he, or ſhe, repreſents, contemptible and unintereſting.

He quits Rome in 1767, without ſtopping till he came to Geneva, where he undertakes twenty female ſcholars, in order to provide for his journey to Paris, and firſt reſidence in that capital. He writes to Voltaire, intreating him to honour a young artiſt, juſt come from Italy, with a lyrical drama, to try his force in a language ſo enriched by his immortal productions. The old bard ſent him word that he could only anſwer his letter *de vive voix*, as he was too ill to write, but deſired to ſee him as ſoon as poſſible. He had the next day a moſt gracious reception at Fernay, of which our author gives an amuſing account. M. Gretry, in his youth, was intereſting in his perſon and pleaſing in his manners; we ſaw, dined, and converſed with him at Paris, three years after this period. And Voltaire, who treated him with great kindneſs, ſeems to have ſeen him in the ſame favourable light. While he was at Geneva he ſet his firſt French opera of "Iſabelle and Gertrude," which was ſo well received, that the audience called for him to receive their acclamations after the manner of Paris. "One of the performers in the orcheſtra, a dancing-maſter, came to me in the morning previous to the repreſentation, to inform me that ſome young people intended to call for me on the ſtage at the end of the piece. I told him I had never ſeen that done in Italy." "You will, however, ſee it here," ſays he, "and you will be the firſt author who has received this honour in our republic." It was in vain for me to diſpute the point: he would abſolutely teach me the bow that I was to make with a proper grace. As ſoon as the opera was finiſhed, they called for me ſure enough, and with great violence, and I was obliged to appear to thank the audience for their indulgence; but my friend in the orcheſtra cries out aloud, "Poh! that is not it!—not at all!—but get along!" "What's the matter," ſay his brethren?" "I am out of all patience; there did I go to his lodgings this morning, on purpoſe to ſhew him how to preſent himſelf nobly, and did you ever ſee ſuch an aukward booby?"

We have then from M. Gretry an account of his arrival and eſtabliſhment at Paris; of the reception of near 30 of his comic operas, and the cabals, difficulties, and hundred headed hydra which he had to encounter, of poets, rival compoſers, performers, &c. Theſe little hiſtories of dramatic intrigues and vexations are frequently mixed with reflections, of which the peruſal might be uſeful to young compoſers for the theatre.

The ſecond and third volumes of M. Gretry's publication are no longer biographical, but a further analyſis of his operas, and of the characters and paſſions which he had to expreſs; in which there is much refinement, ſome caprice, and complete ſelf-ſatisfaction. Many of theſe little eſſays are, however, very ingenious, and well worthy the attention of young dramatic compoſers, and the approbation of the public more than his own.

But when an author praiſes himſelf as liberally as he wiſhes to be praiſed by others, we not only doubt of his modeſty but merits.

The eſſays in the third volume contain many revolutionary principles, and metaphyſical reflections on muſic. At p. 191, however, he begins to treat of the compoſition of muſic, and its technica. In this ſection of his work the chapter on the abuſe of ſcience is the beſt. He gives ſeven *hints* to the young ſtudents, (*aperçus*,) for the amelioration and extenſion of eſtabliſhed rules of compoſition, ſome of which are practicable, but not new; others ſeem hazarded and not defenſible.

The reform of clefs, the ſtaff, ſolmiſation, and diviſions of time, have been frequently propoſed and attempted.

His theory of diſcords, regarding them as *appoggiaturas*, is ingenious and intelligible, and his gammut, *à l'antique*, rigorouſly in the ſame key, aſcending and deſcending, is the only expedient by which the ſcale can be accompanied by fundamental baſes, without two fifths in the tenor part, or modulation into another key. (See *Plate* I.) His arrangement of the chords in thorough-baſe is judicious and elegant, but not new. His ſeventh hint, or *aperçu*, in making the common chord of the key-note ſerve as an appoggiatura of the whole chord to every note of the octave, would perhaps have been more intelligibly expreſſed by *ſuſpenſion* of the whole preceding chord.

M. Gretry, in producing ſo many works during 30 years of his active life, could have little leiſure for reading the elementary books (or the *grimoirs*, as he calls them) that were publiſhing throughout Europe, or he would not have imagined himſelf the original inventor of all the improvements which he has propoſed, and which, from ſo experienced a compoſer, came with ſuch weight, that his work was ordered by government to be printed for the uſe of the ſtudents in the national Conſervatorio at Paris.

Many of his ſhort hints and inſtructions muſt be allowed the merit of ingenuity and refinement, but are too metaphyſical for young ſtudents, and ſometimes not intelligible out of France; ſuch is chap. vi. vol. 3. where the muſical modes or keys are compared with the modes or accents of ſpeech, or the punctuation of a diſcourſe.

His chap. vii. which treats of rhythm, is ſpiritedly written: and his regret is laudable, and implies humanity and feeling for the churches in France being bereaved of their bells, benighted travellers of guides, and the country people of ſinging maſters for tune and tune, of meaſure, and muſical intervals.

M Gretry is not ungrateful to Italy, he ſpeaks with reſpect of its great maſters, and vol. iii. p. 440, note *, he ſtrongly recommends the prevailing on Italian ſingers to eſtabliſh themſelves at Paris. "Italian muſic is the antidote to the evil which we have to cure. I do not mean bad ſingers, who by an ignorant ambition of gracing and embelliſhing every note, leave not a ſingle paſſage of the original melody unadulterated: they are deteſted in Italy as well as in France."

Yet, in his prediction what muſic *will* be in future, (after giving his opinion what muſic *was*, with the Greeks and Romans,) he ſcruples not to ſay, that all muſic which is not ſubſervient to the drama, *à la Françoiſe*, will be rejected by the public; and boaſted four years ago that the Italians were forming all their muſical dramas upon French models. This ſeemed his wiſh, or perhaps his fear, from his knowledge of the depraved taſte of perſons in power; but ſubdued as Italy is by Gallic plunderers, that country, and all civilized Europe, muſt bid adieu to muſic, lyric poetry, painting, ſculpture, and architecture, in the true genuine taſte of that delightful country, ſo emphatically ſtyled the mother and nurſe of the fine arts; with which, in modern times, the globe has been embelliſhed.

Among modern muſical improvements and inventions, mentioned and propoſed by M. Gretry is Erard's invention of an organ, capable of *creſcendo* and *diminuendo*, by greater or leſs preſſure of the *hand* inſtead of the *foot*, (p. 424.) which caught our attention, having long regarded it as one of the moſt important deſiderata in muſic. But upon enquiry, we were ſorry to find that this intelligence was premature: the method uſed, whatever it was, for augmenting the tone by the preſſure of the fingers, over-blew the pipes in ſuch a manner as to render the tone more *acute*, as well as more *powerful*, which would deſtroy all harmonical proportion and true intonation, in the ſame manner as ſinging out of tune.

If the queen of Naples at one time favoured the French opera, it was not becauſe it was French, but German: as Gluck, a native of Germany, who eſtabliſhed the modern French ſtyle of opera, was highly favoured at Vienna, as well as at Parma, where the ſovereign was married to an archduchefs.

When the author tells us (p. 458) that young ſtudents in ſinging at Rome have drawn tears from him, without words, in their *ſolfeggi* upon a ſingle vowel, does it not recommend toleration to the cenſurers of *diviſions* in opera-ſongs? which, when elegant, fanciful, and well-executed, extend the ſenſe of the word to which they are applied, and afford exquiſite pleaſure to ears well organized.

It will, perhaps, be thought by many readers that all the author's praiſe, and all the precepts, tend to one common centre—himſelf and his own works. In every part of his eſſay where he degrades the importance of harmony, and recommends to the young compoſer to begin without its aid and ſupport, by forming ſimple melodies, we wiſhed to diſpute the point; being certain, from our own experience and obſervation, that if counterpoint is not regularly learned early in life, like grammar, and the pronunciation of a language, it is never learned; or ſo ſuperficially, as to leave doubts and perplexities in the mind, which perpetually recur to the end of life.

Many of his precepts are ſpecious and good in theory, but in practice experience has found them fallible, if not impracticable. Why apply muſic to poetry, we may aſk the puriſts, if it does not heighten its colouring, and facilitate its paſſage to the heart?

We have been diffuſive in this article, as the ſubject of it is a profeſſor of great eminence, and his opinions and diſcuſſions are likely to have weight with young muſicians who may ſeek for information in dictionaries. To ſome of his precepts, however, as we cannot implicitly ſubſcribe,

it

it ſeemed neceſſary to aſſign reaſons for our diſſent; at the ſame time allowing all due praiſe to his abilities as a compoſer, and acumen as a muſical critic; lamenting, at the ſame time, the fallibility of human intellect, in the diſtortion of this ingenious man's mind; which, from an admirable artiſt, and an elegant and pleaſing writer, has transformed himſelf near the end of the Revolution, and of his life, to a bad philoſopher, and author of a more offenſive work to pious and good Chriſtians, than *Philoſophiſm*, till then, ever produced, entitled "De la Verité; ce que nous fûmes, ce que nous ſommes, ce que nous devons être." And may we not venture to aſk citizen Gretry, what dæmon had inſpired him with more knowledge on theſe mattees than the greateſt theologians, metaphyſicians, or atheiſts, of ancient and modern times?

GRETZER, James, a learned German Jeſuit, was born at Marckdorf in the year 1560. He entered into the order at the age of ſeventeen, and applying himſelf with great ardour to his ſtudies, he became a proficient in ancient and modern literature: in philoſophy, theology, and antiquities. He ſucceſſively filled the chairs of philoſophy, morals, and divinity during 25 years, in the univerſity of Ingoldſtadt, where he died in 1625, at the age of 65. He left behind him a collection of controverſial pieces in two volumes folio, printed at Ingoldſtadt. He was author, likewiſe, of a great number of treatiſes in profane and eccleſiaſtical antiquities, of which the moſt celebrated is entitled "De Cruce," in three volumes quarto. According to Dupin, the works of Gretzer, though not of the firſt rank in literary merit, will furniſh very good materials to thoſe who would write on the ſame ſubjects. He was well verſed in the Greek tongue, and publiſhed ſome grammatical pieces in that language, together with notes on certain Greek authors. His works, amounting in number to one hundred and fifty-three, were collected and printed at Ratiſbon in 1739, in 17 vols. folio. Moreri. Dupin.

GREVE, Gerefa, among our *Ancient Writers*, is a denomination of power and authority; ſignifying as much as *comes* or *vicecomes*. See Count and Viscount.

The word is formed from the Anglo-Saxon *grith*, *peace*. Thus Hoveden: "Greve dicitur, ideo quod jure debeat grith, *i. e.* pacem ex illis facere, qui patriæ inferunt væ, *i. e.* miſeriam vel malum."

Lambard makes greve the ſame with *reve*.

Hence, alſo, the words *ſhrieve*, *portgreve*, &c. which were anciently written *ſciregereſa*, *portgereſa*, &c.

Greve, in *Geography*, a town of Etruria; 14 S. of Florence.

Greve *au Lanchau*, a bay on the N. W. coaſt of the iſland of Jerſey.

Greve *de Lecq*, a bay on the N. coaſt of the iſland of Jerſey.

GREVEN, a town of the biſhopric of Munſter; eight miles N. of Munſter.

GREVENBROICH, a town of France, in the department of the Roer; ten miles N. N. E. of Juliers.

GREVENSTEIN, a town of Weſtphalia; 16 miles W. of Brilon.

GREVILLE, Fulke, *lord* Brooke, in *Biography*, was born at Beauchamp's-Court, in Warwickſhire, in 1554. He received his education, partly at Cambridge and partly at Oxford, but chiefly at Trinity-college, Cambridge. From college he went on foreign travel, and on his return was introduced to queen Elizabeth's court, and became the favourite of his ſovereign. She exhibited her regard in a manner not very pleaſing to one of his gallant ſpirit, by reſtraining him from taking part in ſome martial enterprizes abroad, on which his mind was fully bent. He procured but little advancement during this reign, and it was chiefly through the intereſt of ſir Henry Sidney that he obtained two lucrative poſts in the courts of the marches of Wales. In 1597 he received the honour of knighthood, and, two years afterwards, the office of treaſurer of marine cauſes. He ſat in ſeveral parliaments as member for the county of Warwick; and part of one of his ſpeeches on eſtabliſhing precedents has been quoted by lord Bacon. "Why," ſaid he, "ſhould you ſtand ſo much upon precedents? The times hereafter will be good or bad: if good, precedents will do no harm: if bad, power will make a way where it finds none." On the acceſſion of king James he was created a knight of the Bath, and ſoon after had a grant of the caſtle of Warwick, on which he expended on neceſſary repairs twenty-thouſand pounds. In 1614 he was made under-treaſurer, and chancellor of the exchequer, and admitted into the privy-council, and in 1620 he was raiſed to the dignity of a peerage, by the title of lord Brooke of Beauchamp's-Court. He was ſtabbed by a domeſtic whom he had reprimanded for inſolence. He was diſtinguiſhed as a patron of letters, and in 1627, the year before his death, he founded at Cambridge a profeſſorſhip of hiſtory with a handſome ſalary. As an author few of his compoſitions were made public till after his death. In 1632 ſeveral poetical works appeared under his name. Of his proſe writings the moſt intereſting is the life of ſir Philip Sidney, his particular friend. His poetry is generally negligent and flat, but there are occaſional paſſages extremely harmonious. In proſe his ſtyle is affected and involved, yet diſplaying a full mind and a large acquaintance with various learning. Biog. Brit.

GREVILLEA, in *Botany*, named by Mr. R. Brown, in honour of the late right honourable Charles Francis Greville, F. L. S. a vice preſident of the Royal Society, in whoſe garden at Paddington the rareſt and moſt curious plants, from various climates, were cultivated with peculiar ſucceſs, and always devoted to the real advancement of ſcience. Since his death in 1809, the collection has unfortunately been diſperſed. Brown Tr. of Linn. Soc. v. 10. 167. Prod. Nov. Holl. v. 1. 375. Dryand. in Ait. Hort. Kew. ed. 2. v. 1. 204. (Embothrii ſpecies; Sm. New Holl. 25, 29.) See Embothrium.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteæ*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals four, cohering by their lower part into a tube, linear, oblique, at length revolute; their ſummits dilated, concave, bearing the ſtamens. *Stam.* Filaments four, extremely ſhort, inſerted into the hollow in the tip of each petal; anthers roundiſh, ſunk in the ſaid hollow. *Piſt.* Germen ſuperior, ſtalked, half-ovate, erect, with a gland on one ſide at the baſe of its ſtalk; ſtyle incurved; ſtigma oblique or lateral, depreſſed, or ſomewhat convex. *Peric.* Follicle ſtalked, half-ovate, coriaceous, ſometimes woody, crowned with the ſtyle, of one central cell. *Seeds* two, elliptical, compreſſed, with a very ſhort margin or wing, by which they are attached to the top of the follicle.

Eſſ. Ch. Petals four, oblique. Stamens ſunk in the cavities of the limb. A lateral gland at the baſe of the ſtalk of the germen. Stigma oblique. Follicle coriaceous or woody, of one central cell. Seeds two, ſlightly winged.

The moſt extenſive genus of its natural order in New Holland, of which country all its 38 ſpecies, defined by Mr. Brown, are natives. When but few of them were known, and their alliances but ill underſtood, it was thought ſafeſt to comprehend them under *Embothrium*, notwithſtanding the fewneſs of their ſeeds, and the ſame caution was uſed in determining their ſpecies, ſeveral having been conſidered

as varieties, which Mr. Brown, having had ſuch abundant opportunities of ſtudying them in their native land, has raiſed to the rank of ſpecies. Even thus ſeparated from its parent *Embothrium*, *Grevillea* comprehends plants that differ greatly in appearance, and in ſome ſubordinate characters, from each other, ſo as to be commodiouſly divided into two principal ſections, the firſt of which is ſub-divided into five ſub-diviſions. We ſhall give one example, or more, of each.

Section I.

Follicle coriaceous, crowned with the entire ſtyle and its depreſſed ſtigma. Seeds oval, very minutely bordered, and crowned with a very ſhort wing.

A. Lissostylis, (from λισσος, *ſmooth*, and στυλος, *the ſtyle*.)

Leaves all entire, in many inſtances having their margins acutely reflexed at the lateral nerves. Flowers faſciculate, or in ſhort cluſters. Style ſmooth. Follicle without ribs.—Thirteen ſpecies, examples of which are

G. *punicea*. (Embothrium fericeum β; Sm. Bot. of N. Holl. 27. t. 9. f. 5.)—Leaves elliptic-oblong, ſomewhat tapering at the baſe, reflexed at the margin. Flowering branches and cluſters recurved. Upper half of the claws of the petals denſely bearded within. Native of the country near Port Jackſon, New South Wales. A *ſhrub* four or five feet high, flowering in October. *Stem* very much branched, round, the younger branches angular and ſomewhat ſilky, leafy. *Leaves* ſcattered, ſolitary or ternate, about an inch and half long, elliptic-oblong, ſometimes obovate, obtuſe, entire, rather coriaceous, tipped with a ſmall point; green and nearly ſmooth above; white and ſilky beneath; with a prominent middle rib, and a lateral one near each edge, which, from the flexure of that part, becomes the actual border of the leaf, and is roughiſh to the touch; the baſe tapers ſlightly into a ſhort, thickiſh, angular, ſilky *footſtalk*, dilated at the bottom. *Stipulas* none. *Flowers* crimſon, inodorous, in ſhort, denſe, ſilky, corymboſe cluſters. *Corolla* externally ſilky, about half an inch long in its revolute poſition; the upper half, or rather more, of the inſide of the claws, is lined with very denſe, long, prominent hairs. *Style* an inch long, rather thick. *Stigma* inflexed or lateral, but without any projection of the ſtyle beyond it.—We have not ſeen this ſpecies in any garden.

G. *fericea*. (Embothrium fericeum α; Sm. Bot. of N. Holl. 25. t. 9. f. 1—4. Andr. Repoſ. t. 100. Sims in Curt. Mag. t. 862. Willd. Sp. Pl. v. 1. 539. E. cytiſoides; Cavan. Ic. t. 386. f. 2.)—Leaves elliptical, obtuſe, with a ſmall point, reflexed at the margin. Flowering branches erect. Cluſters recurved. Summit of the claws of the petals denſely bearded within.—From the ſame country, where it is apparently more common than the former. It has flowered in ſeveral collections about London. Every part is about half the ſize of the preceding. *Leaves* more elliptical, with a ſtronger point, their baſe not tapering. *Flowers* paler, or purpliſh, eſſentially diſtinguiſhed, as Mr. Brown firſt remarked, by the internal beard of the claws being confined nearly to their ſummit, not ſpreading downward, more than half way to the baſe. The *ſtyle* is rather above half an inch in length, and crowns the black ovate *fruit*, long after the latter has burſt on one ſide and diſcharged its ſeeds.

G. *linearis*. (Embothrium lineare; Andr. Repoſ. t. 272. E. linearifolium; Cavan. Ic. t. 386. f. 1. E. fericeum γ; Sm. Bot. of N. Holl. 27. t. 9. f. 6.)—Leaves linear-lanceolate, with a ſmall point, reflexed at the margin. Cluſters ſhort, nearly upright. Style ſmooth to the very top.—Native of ſtony places near the beach at Port Jackſon. This has longer narrower *leaves*, and paler or whitiſh *flowers*, in more upright cluſters, than the laſt, with which it otherwiſe agrees in habit and appearance.

We have a plant from the ſame neighbourhood, with rather broader and more obtuſe leaves, whoſe margin and marginal ribs are rough with minute teeth, according to the character of Mr. Brown's next ſpecies, *G. ſtricta*, but its ſtyles are ſmooth to the very top, as in the three foregoing, not "ſilky at the ſummit."

With the remaining ſpecies of this ſubdiviſion we are unacquainted.

B. Ptychocarpa, (from πτυχη, *a plait*, and καρπος, *fruit*.)

Leaves all entire. Flowers faſciculate, or in ſhort cluſters, the uppermoſt opening firſt! Stalk of the germen very ſhort. Style hairy or downy. Follicle ribbed!—Six ſpecies, all natives of the neighbourhood of Port Jackſon, in mountainous, heathy, ſandy, or ſtony places, as

G. *arenaria*. "Leaves oblong, obtuſe, with a ſmall point. Cluſters of few flowers, recurved. Piſtils downy."—This is in Kew garden, where it flowers frequently.

C. Eriostylis, (from εριον, *wool*, and στυλος, *the ſtyle*.)

Leaves all entire. Flowers faſciculate, ſomewhat umbellate. Piſtil woolly, ſtalked. Follicle without ribs.—Four ſpecies, as

G. *buxifolia*. (Embothrium buxifolium; Sm. Bot. of N. Holl. 29. t. 10. Andr. Repoſ. t. 218. E. genianthum; Cavan. Ic. t. 387.)—Leaves elliptical, revolute; rough and dotted above; clothed with cloſe pale down beneath. Stigma orbicular, ſurmounted by the reflexed point of the ſtyle.—Grows near Port Jackſon, flowering in November. Meſſrs. Lee and Kennedy raiſed it in 1790, and it flowered with them in 1795. The habit is like that of a *Phylica*. *Leaves* numerous, ſcarcely an inch long. *Flowers* numerous, in terminal, ruſty, hairy umbels; the inſide of the corolla, as well as the ſtyle, equally hairy, but white. The large lateral ſtigma, conſiderably below the end of the ſtyle, is remarkable. The *fruit* is tumid and roughiſh.

D. Plagiopoda, (from πλαγιος, *oblique*, and πους, *the foot*.)

Cluſter denſe. Stalk of the germen running into the oblique apex of the flower-ſtalk, into which are inſerted, on each ſide, two of the petals, one above the other.

Two ſpecies only compoſe this ſub-diviſion, both growing within the tropic.

G. *Goodii*. "Leaves entire, oblong, waved, veiny, ſmooth on both ſides. Cluſters ſtalked, elongated. Stems proſtrate."

G. *venuſta*. "Leaves pinnatifid, trifid, or undivided, ſilky beneath. Cluſters erect. Corolla quite ſmooth. Style very hairy.

E. Grevillea properly ſo called.

Cluſter denſe. Leaves pinnatifid, rarely here and there undivided.

Five ſpecies, found in various parts of New Holland. To theſe Mr. Brown wiſhes to reſtrain the name of *Grevillea*, in caſe his various ſub-diviſions ſhould each be hereafter exalted to the rank of a genus, by the names which he has invented. They are very handſome ſhrubs, as

G. *pungens*. "Leaves pinnatifid; ſmooth above; ſilvery beneath; their ſegments linear, ſomewhat awl-ſhaped, pointed and pungent. Cluſters bent backwards. Corolla and piſtil very ſmooth."

G. *Chryſodendrum*. "Leaves ſimply or doubly pinnatifid; their ſegments linear, narrow, and elongated. Cluſters cylindrical. Flowers half whorled. Corolla downy, its baſe permanent. Germen nearly ſeſſile. Style ſmooth."

Both theſe grow near the ſhore on the north coaſt of New Holland, in Carpentaria.

SECTION II.

Follicle woody, roundiſh, pointed with only the baſe of the ſtyle. Seed ſurrounded on all ſides with a broadiſh wing.

CYCLOPTERA, (from *κυκλος*, *a circle*, and *πτερον*, *a wing*.) Of this ſection there are eight ſpecies. They agree in the woody texture of their follicle with our *Conchium*, (which ſee,) but differ in the cell being central, not excentric, as well as in the circular wing of the ſeeds. They are all tropical plants, various in their leaves, which are either pinnate, trifid, undivided, flat, or cylindrical. Flowers racemoſe.—Examples are

G. *helioſperma*. "Leaves pinnate or bipinnate, ſmooth; their pinnæ oblong or ſomewhat linear; the lowermoſt ſtalked. Cluſters divided, erect. Corolla and piſtil very ſmooth."

G. *mimoſoides*. "Leaves entire, ſword-ſhaped, flat, ribbed, ſmooth, as well as the branches. Follicles obovate; viſcid."

G. *lorea*. "Leaves cylindrical, pendulous, very long. Stigma quadrangular, forming a truncated pyramid."—The fruit of this has not been ſeen by Mr. Brown.

G. *gibboſa*. "Leaves lanceolate, elongated, entire, ſlightly downy, ſingle-ribbed, veiny. Cluſters elongated. Stigma conical. Follicles thickened and gibbous."

This laſt is a ſort of connecting link between the cyclopterous *Grevilleæ* and *Conchium*, the *Hakea* of Mr. Brown.

GREVIN, JAMES, in *Biography*, a poet and phyſician, was born at Clermont in 1538. He was very early diſtinguiſhed by his knowledge of languages, philoſophy, and the belles lettres, and aſtoniſhed the people of Paris, by bringing out a tragedy and two comedies, when he was only 13 or 14 years of age. He took the degree of doctor of phyſic at Paris in 1561. It was principally through his exertions and repreſentations, that the abſurd decree of the faculty of Paris, afterwards confirmed by parliament, againſt the uſe of antimony in medicine was paſſed. He was phyſician to Margaret, ducheſs of Savoy, whom he accompanied to Piedmont; and he died at Turin when only 32 years of age. His poems were much praiſed, and deemed equal to any of his age, but have been ſuperſeded by the greater excellence of ſucceeding writers. In medicine he publiſhed a "Treatiſe on Poiſons," and an abridgment of the anatomy of Veſalius, both in Latin and French. Eloy. Dict. Hiſt.

GREUSSEN, in *Geography*, a town of Germany, in the county of Schwartzburg; 16 miles N. of Erfurt. N. lat. 51° 6′. E. long. 11° 3′.

GREW, NEHEMIAH, in *Biography*, the firſt and moſt univerſal vegetable anatomiſt and phyſiologiſt of this country, was born at Coventry, where his father Obadiah Grew, D.D. was vicar of St. Michael's church. The year of his birth is not mentioned. He was brought up a preſbyterian, his father having taken the covenant, and on the change of the national form of religion, at the reſtoration of Charles II. he was ſent to ſtudy in ſome foreign univerſity, where he took his degree of Doctor of Phyſic. He ſettled firſt at Coventry, and probably reſided there in 1664, when, as he informs us in the preface to his Anatomy of Plants, he firſt directed his thoughts to the ſubject of that work, "upon reading ſome of the many and curious inventions of learned men, in the bodies of animals. For conſidering that both of them came at firſt out of the ſame hand, and were therefore the contrivances of the ſame wiſdom; I thence," ſays he, "fully aſſured myſelf, that it could not be a vain deſign, to ſeek it in both.—That ſo I might put ſomewhat upon that ſide the *leaf* which the beſt *botanicks* had left bare and empty."—Four years afterwards he conſulted his brother-in-law Dr. Henry Sampſon, who encouraged him to go on, by pointing out a paſſage in Gliſſon's book *de Hepate*, chap. 1, in which the anatomy of plants is hinted at as an unexplored, but very promiſing, line of ſtudy for a practical obſerver.—Dr. Grew's firſt eſſay on this ſubject was communicated to the Royal Society in 1670, by biſhop Wilkins, under the title of an Idea of a Philoſophical Hiſtory of Plants. It was received with the honour and attention it deſerved, being ordered to be printed, and its author was invited to ſettle in London, with which he complied in 1672, and in that year alſo, on the recommendation of the ſame learned divine, he became a fellow of the Royal Society. He was appointed ſecretary in 1677, in which capacity he publiſhed the Philoſophical Tranſactions from Jan. 1677-8, to Feb. in the following year. In 1680 he was made an honorary fellow of the College of Phyſicians.—He is ſaid to have attained to conſiderable practice in his profeſſion, nor did his heterodox origin deprive him of the credit juſtly due to his piety and philoſophical merit, even in the worſt times. He lived indeed to ſee various changes of opinions and profeſſions, apparently with the tranquillity becoming a philoſopher and a good man, and died in 1711.

Dr. Grew's Anatomy of Vegetables, of Roots, and of Trunks, originally formed three ſeparate publications in 8vo. but were ſubſequently collected into a folio volume, and publiſhed in 1682, with 83 plates. In this work, truly original, though Malpighi had about the ſame time, or rather before, purſued the ſame line of enquiry, ſcarcely any thing relative to the vegetable anatomy is left untouched. It was the character of Grew to obſerve every thing, and if a more philoſophical obſerver, more aware of what is beſt worth remarking, be, in general eſtimation, a ſuperior character, the latter is more likely to ſee through the falſe medium of dazzling theory. The works of Grew are a ſtorehouſe of facts, for the uſe of leſs original and more indolent authors. They ſeldom require correction, except where theory is interwoven with obſervation, and even his theories have paſſed current till very lately. His chemiſtry is, of courſe, that of his time, but his remarks on vegetable ſecretions, and their multifarious and peculiar properties, abound with ingenuity and originality, as well as his comparative examinations of the various kinds of fruits and ſeeds. If he had no correct ideas of the propulſion or direction of the ſap, we muſt not forget that he was one of the firſt who adopted and illuſtrated the doctrine of the ſexes of plants, nor did even the principles of methodical arrangement entirely eſcape his notice.

In 1681 Dr. Grew publiſhed a folio volume, entitled *Muſæum Regalis Societatis*, or a catalogue and deſcription of the Natural and Artificial Rarities belonging to the Royal Society, and preſerved at Greſham College. This is a ſcientific and deſcriptive catalogue, with learned references to preceding writers. It is accompanied by "the Comparative Anatomy of Stomachs and Guts begun, being ſeveral lectures read before the Royal Society in 1676." Twenty-two plates illuſtrate the firſt part of this volume, and nine the latter.

The lateſt publication of our author, we believe, was "Coſmographia Sacra, or a Diſcourſe of the Univerſe, as it is the creature and kingdom of God." He was an illuſtrious proof that it is the *fool*, and not the *philoſopher*, who "hath ſaid in his heart *there is no God*." On this ſubject we need not repeat our remarks under the article FUCHSIUS.

The works of Grew were ſoon tranſlated into French and Latin.

Latin. Of the incorrectneſs of the latter, done in Germany, he complains in ſtrong terms. A foreigner might perhaps be perplexed by his ſtyle, which in his earlier performances is ſcarcely equal to the good writers, even of the time in which he lived. Haller appears to have ſtudied and underſtood him with his uſual ſagacity and accuracy.—Grew's works. Haller's Bibl. Bot. Aikin's Gen. Biogr. S.

GREWENMACHEE, a town of France, in the department of the Forêts, and chief place of a canton, in the diſtrict of Luxemburg. The place contains 1867, and the canton 9085 inhabitants, on a territory of 207½ kiliometres, in 17 communes.

GREWESMUHLEN, a town of Mecklenburg; 14 miles W. of Wiſmar. N. lat. 53° 35'. E. long. 11° 15'.

GREWIA, in *Botany*, ſo named by Linnæus, in memory of the great vegetable anatomiſt Dr. Nehemiah Grew; ſee that article.—Linn. Gen. 469. Schreb. 356. Willd. Sp. Pl. v. 2. 1164. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 313. Juſſ. 292. Lamarck Illuſtr. t. 467. Gærtn. t. 106. (Mallococca; Forſt. Gen. t 39. Chadara; Forſk. Ægypt. Arab. 105.)—Claſs and order, *Polyandria Monogynia*. (*Gynandria Polyandria*, Linn.) Nat. Ord. *Columniferæ*, Linn. *Tiliaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, ſtraight, coriaceous leaves, coloured on their inſide, ſpreading, deciduous. *Cor.* Petals five, the ſhape of the calyx, often ſmaller, emarginate at the baſe. Nectary? a ſcale inſerted into the baſe of each petal, thickiſh, incurved, inclined at the margin, and embracing the ſtyle. *Stam.* Filaments very numerous, briſtle-ſhaped, the length of the petals, inſerted into the baſe of the germen; anthers roundiſh. *Piſt.* Germen roundiſh, ſupported by a column crowned with a five-ſided border, at the baſe of which the petals are inſerted, and at its top the ſtamens; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma obtuſe, four-cleft. *Peric.* Berry moſtly of four lobes and four cells. *Seeds* ſolitary, globoſe, uſually two-celled.

Eſſ. Ch. Calyx of five leaves, coloured within. Petals five, with a ſcale at the baſe of each. Berry ſtalked, of ſeveral cells. Seeds ſolitary.

Obſ. Juſſieu remarks that the honey is really ſecreted by the column, between the corolla and ſtamens. If ſo, the ſcales of the petals are incorrectly termed nectaries. The ſtamens not being inſerted into the piſtil above the germen, this genus belongs to *Polyandria*, next to its near relation *Tilia*, inſtead of *Gynandria*, where Linnæus placed it. The ſpecies which compoſe it have undergone ſeveral revolutions, and ſome of thoſe, included by Linnæus, are now removed to other genera, as *Microcos* and *Alangium*; ſee Willd. v. 2. 1168, 1174; ſee alſo *Lemniſcia*, 1172, which we believe belongs to the latter. Some Eaſt Indian *Grewiæ* have been ill-underſtood, ſo that we find it neceſſary to attempt a review of the whole. They are all ſhrubs or trees, with the habit of Elms, or Lime-trees, with very handſome, though not large, flowers.

1. G. *occidentalis*. Linn. Sp. Pl. 1367. Curt. Mag. t. 422, not 423. Duham. Arb. 276. t. 108. (Ulmi facie arbuſcula Æthiopica, ramulis alatis, floribus purpuraſcentibus; Comm. Hort. v. 1. 165. t. 85.)—Leaves roundiſh-ovate, bluntly ſerrated, ſmooth. Flower-ſtalks ſolitary, club-ſhaped, ſingle-flowered.—Native of the Cape of Good Hope, long cultivated in our green-houſes, where it flowers moſt part of the ſummer. It is ſaid to have been in the royal collection at Hampton Court in 1692, having been, doubtleſs, imported from Holland. This ſpecies is a *ſhrub*, 10 or 12 feet high, much branched, the branches nearly ſmooth. *Leaves* alternate, ſtalked, broad-ovate, rounded, bluntiſh, rather crenate than ſerrated, ſmooth, an inch or more in length, ſomewhat oblique, and much reſembling thoſe of an elm, deciduous. They have three principal nerves, and numerous veins. *Footſtalks* thickiſh, hairy, not a quarter the length of the leaf. *Stipulas* very ſhort, triangular, deciduous. *Flower-ſtalks* axillary, ſolitary, about half as long as the leaf, ſwelling and ſomewhat angular upwards, downy, ſingle-flowered, furniſhed with a joint, at which are ſituated two or three lanceolate *bracteas*, that are very ſoon deciduous. *Flowers* above an inch wide, their calyx externally green and downy, internally pale purple, like the petals, whoſe ſcales at the baſe are of a deeper hue. We have not ſeen the fruit.

2. G. *populifolia*. Vahl. Symb. v. 1. 33. (Chadara, n. 23; Forſk. Ægypt. Arab. 105.)—Leaves orbicular, bluntly ſerrated, roughiſh beneath. Flower-ſtalks ſolitary, thread-ſhaped, ſingle-flowered, longer than the leaves.—Native of Arabia, where it is called *Chadár* or *Nabba*; alſo of the Eaſt Indies. A *ſhrub*, much branched and divaricated. *Leaves* ſhorter and rounder than the former, on longer more ſlender ſtalks. *Flower-ſtalks* alſo much more ſlender, ſlightly thickened upwards, with three linear-obovate deciduous *bracteas*. *Flower* about half the ſize of the preceding. The under ſide of the leaves is rough with minute, ſtarry, ruſty hairs.

3. G. *orientalis*. Linn. Sp. Pl. 1367. (Pai-Parſea; Rheede Hort. Mal. v. 5. 91. t. 46. Frutex baccifer malabaricus; Pluk. Phyt. t. 50. f. 4.)—Leaves ovate, pointed, finely and bluntly ſerrated, roughiſh. Flower-ſtalks three-flowered. Petals revolute. Column very briſtly.—Native of the Eaſt Indies. A *ſhrub* ſix feet high, with circularly ſpreading branches. *Leaves* near three inches long, on ſhort rough ſtalks, exactly ovate with an elongated point, cloſely and bluntly ſerrated, or rather crenate, throughout, roughiſh to the touch on both ſides, finely veiny, their ribs more or leſs briſtly. *Stipulas* lanceolate, keeled, very briſtly at the back, rather longer than the footſtalks. *Flower-ſtalks* about half the length of the leaves, hairy, bearing three flowers, their partial ſtalks either all ſpringing from the joint, with ſeveral lanceolate bracteas, or one of them ſtands below the other two, in which caſe the firſt is accompanied by a leaf. *Flowers* larger than thoſe of G. *occidentalis*, with broadiſh revolute petals, ſhorter than the calyx. The *column* is clothed with long, denſe, ſilky, briſtles, from juſt above the inſertion of the petals to the baſe of the ſtamens, as is the germen alſo. *Fruit* near an inch broad, four-lobed, depreſſed, clothed with denſe ſhort briſtles.—We are the more particular in deſcribing this ſpecies, becauſe Vahl and Gærtner ſeem to have miſtaken another for it. We received it long ago from Dr. Roxburgh for the *Microcos*, but that is totally different. We have likewiſe from the Eaſt Indies a plant whoſe leaves are leſs accurately ovate, and rather elliptic-oblong, the petals longer and ſcarcely revolute, but every other part ſo preciſely agrees, that we dare not make it diſtinct, eſpecially as the laſt-mentioned character may depend on the age of the flower.

4. G. *piloſa*. Lamarck. Dict. v. 3. 43. (G. orientalis; Gærtn. v. 2. 112. t. 106. Vahl. Symb. v. 1. 34.)—Leaves elliptic-oblong, ſharply and unequally ſerrated, rough on both ſides with ſtarry hairs. Flower-ſtalks three-flowered. Petals ſtraight, nearly equal to the calyx. Column naked.—Native of the Eaſt Indies. This appears to be Gærtner's orientalis by the fruit, the only part, perhaps, known to him, and which is only one-third the ſize of the laſt, though more deeply lobed. It anſwers exactly to Vahl's deſcription of his *orientalis*, and to Willdenow's variety mentioned in his Sp. Pl. under that ſpecies. Nor can we poſitively aſſert

aſſert it is not that of Linnæus, which can be determined only by Hermann's herbarium; but it neither accords with his deſcription nor ſynonyms. Whether it be Burmann's in Fl. Ind. 192. can ſeem ſcarcely worth enquiry, as this author quotes for a variety Rumph. Amb. v. 4. t. 60, *Frutex ceramicus*, a plant as different in every eſſential character as can well be. In this difficulty we have choſen rather to adopt Lamarck's name, as above. The ſhape, and denſe ſtarry pubeſcence, of the *leaves* ſufficiently diſtinguiſh it from the preceding. The *petals* are almoſt as long as the calyx, ſtraight, linear, often jagged at the end. The ſmoothneſs of the *column*, which is merely crowned with hairs under the germen, affords a beautiful and clear diſtinction, very apparent under the ripening fruit. See Gærtner's figure.—Lamarck's deſcription is extremely accurate, but his ſynonyms miſapplied.

5. G. *columnaris*.—Leaves ovate-oblong, crenate, rough on both ſides. Flower-ſtalks three-flowered. Column hairy, twice the length of the germen.—Native of the Eaſt Indies, from whence we have received ſpecimens, ſometimes for *orientalis*, ſometimes for *Malococca*. It differs eſſentially from both in its long, hairy column, twice or even thrice as long as the germen it ſupports, and acutely five-angled. The *leaves* greatly reſemble ſome kind of elm, and are rather glaucous, above two inches long, on ſhort hairy ſtalks, ſomewhat heart-ſhaped at the baſe, pointed, unequally crenate rather than ſerrated throughout. Both ſides are very rough to the touch, with minute, ſcattered, ſtarry hairs, as are alſo the ribs beneath. *Stipulas* awl-ſhaped, about equal to the footſtalks, deciduous. *Flower-ſtalks* not half ſo long as the leaves, denſely covered with ſtarry hairs, three-cleft, often but a little above their baſe, and bearing numerous, recurved, lanceolate bracteas, ſmooth on their upper ſide. *Petals* we believe ſhort and recurved. *Fruit* clothed with longiſh, ſtraight, ſcattered hairs, which are alſo remarkable in the young germen, being much longer than thoſe which clothe its column.

6. G. *Mallococca*. Linn. Suppl. 409. Cavan. Ic. t. 369. (Mallococca crenata; Forſt. Gen. 39. Nov. Act. Upſ. v. 3. 180.)—Leaves ovate-oblong, crenate, rough on both ſides; ribs briſtly. Flower-ſtalks three-flowered. Column very ſhort and naked.—Gathered by Forſter in the groves of the iſland of Tongatabu, and on the mountains of the iſland of Huaheine. This bears a conſiderable affinity in character to the laſt, and in habit to *G. piloſa*. The *leaves* are three or four inches long, one and a half or two in breadth, ovate, pointed, often heart-ſhaped at the baſe, crenate throughout, copiouſly veined, of a fine deep ſhining green, roughiſh to the touch on both ſides, with ſome appearance of ſtarry hairs when young; their ribs briſtly beneath. *Footſtalks* half an inch long, thick, hairy. *Stipulas* awl-ſhaped, ſoon deciduous. *Flower-ſtalks* moſtly in pairs, not half ſo long as the leaf, hairy. *Petals* ſhort, ovate, pointed, erect. *Column* ſo ſhort as to be ſcarcely perceptible in the flower, but as the fruit advances it becomes ſufficiently viſible, near a line in length, obconical, ſmooth, crowned with a hairy border. The *fruit* is four-lobed, the ſize of *Euonymus europæus*, but hairy, whence Forſter's name, from *χαιτη*, *hairy*, and *κοκκος*, *a berry*. He may well be juſtified, as *Grewia* was then defined, for making this plant a new genus, and it is far more aſtoniſhing that the younger Linnæus ſhould, in the *Supplementum*, mention a difficulty in tracing out a ſpecific difference.

7. G. *lævigata*. Vahl Symb. v. 1. 34. (G. Damine; Gærtn. v. 2. 113. t. 106.)—Leaves elliptic-lanceolate, pointed, ſerrated, ſmooth on both ſides, entire at the baſe. Flower-ſtalks three-flowered. Column ſhort and naked.—Native of the Eaſt Indies. The *branches* are ſlender, purpliſh brown, beſprinkled with white, cloſe-preſſed, cluſtered hairs. *Leaves* on ſhortiſh hairy ſtalks, about two inches long, dark green, veiny, naked, ſmooth, or very ſlightly roughiſh to the touch, elliptic-lanceolate, or ſomewhat obovate, being an inch broad rather beyond the middle, with an elongated ſharp point. They are ſerrated throughout, except at the very baſe, which is entire, ſmooth, and in ſome degree contracted. *Stipulas* awl-ſhaped. *Flower-ſtalks* axillary, ſolitary, ſcarcely half ſo long as the leaf, three-cleft half way down, divaricated, beſprinkled with a few cloſe ſhort briſtles, as if dotted. *Flowers* ſmaller than in any of the foregoing. *Petals* ſhort, erect, acute. *Column* rather longer than in the laſt, five-ſided, quite ſmooth and naked, except at the top, where it is dilated, and crowned with a circle of hairs as in other ſpecies. *Germen* didymous, very ſlightly hairy when young, ſoon becoming quite ſmooth. *Fruit* commonly of two ſmooth grains, the ſize of a pea. It exactly reſembles *G. Damine* of Gærtner, but we find only two cells in each ſeed.

8. G. *glanduloſa*. Vahl. Symb. v. 1. 34.—Leaves ovato-lanceolate, pointed, crenate, nearly ſmooth on both ſides; glandular at the baſe. Flowers nearly ſeſſile.—Native of the iſland of Mauritius. *Branches* roughiſh. *Leaves* on rough ſtalks, three inches long, light green, ovato-lanceolate, pointed, above an inch broad, veiny, firm, naked on both ſides, but not without ſome ſlight roughneſs to the touch. The margin is crenate throughout, and the baſe is remarkable for four or five glandular marginal tubercles on each ſide. The *flowers* reſemble ſome of the earlier ſpecies, and are axillary, on very ſhort, thick, ſimple ſtalks, we are not ſure whether ſolitary or in pairs, nor will our ſpecimen admit of an inveſtigation of the organs of fructification. The *petals* ſeem to be dilated or obovate, and almoſt as long as the calyx.

9. G. *birſuta*. Vahl. Symb. v. 1. 34.—Leaves ovato-lanceolate, finely downy, ſerrated, unequal at the baſe. Stalks many-flowered. Calyx very hairy.—Native of the ſummits of mountains in the Eaſt Indies. *Vahl.* Received with ſome Java plants from profeſſor Thunberg. Every part, to the inſide of the calyx, is clothed with very ſoft, denſe, ſhort pubeſcence. *Leaves* on ſhort ſtalks, four inches long, one and a half broad, ovate but unequal, ſo as to be half cordate, at the baſe, tapering to an acute point, ſharply ſerrated throughout; their ribs prominent beneath, with numerous ſtraight tranſverſe veins; the upper ſurface is leſs downy, and very finely reticulated. *Stipulas* awl-ſhaped, as long as the footſtalks. *Flower-ſtalks* not much longer, three together, axillary, umbellate, and bearing many ſmall flowers; Vahl ſays but three, yet we ſee no reaſon to doubt his being the ſame as our's. *Bracteas* nearly equal to the partial ſtalks. *Petals* ſhort, oblong, acute, fringed.

10. G. *asiatica*. Vahl. Symb. v. 1. 35. (Chadara arborea; Forſk. Ægypt. Arab. 105.) Leaves oval-oblong, ſerrated, unequal at the baſe; rough above; downy and white beneath. Stalks two or three-flowered.—Gathered by Forſkall on the mountains of Yemen. The Arabs call it *Særak*. We have what agrees with Forſkall's full deſcription, gathered by Dr. Buchanan in the Eaſt Indies, the preciſe place not ſpecified, only our ſpecimen retains no other part of the fructification than the half-grown *germen*, which is turbinate, very hairy, on an extremely ſhort but ſmooth column.—This is ſaid to be a large *tree*. The *leaves* are three or four inches long, green and rough above, very white and downy beneath, unequal like the foregoing at their baſe, on ſhort thick hairy footſtalks. *Stipulas* lanceolate, downy. *Flower-ſtalks* one, two, rarely three or four together,

ther, one, two or three-flowered, divaricated, hairy, not half so long as the leaves.

11. G. *asiatica*. Linn. Mant. 122. Sonnerat. Voy. v. 2. 244. t. 138. Vahl. Symb. v. 1. 35.—Leaves roundish, somewhat heart-shaped, serrated, unequal at the base: white and downy beneath. Flower-stalks aggregate, much longer than the footstalks. Column naked, as long as the germen.—Native of the East Indies. Sent to Linnæus from Surat. Sonnerat says it is cultivated in the gardens at Pondicherry. The *leaves* have very much the aspect of the white American lime tree, *Tilia alba*, and differ from all the preceding in their rounded, heart-shaped, unequal-sided figure. They are two or three inches in diameter, unequally serrated, roughish above, snow-white and finely downy, with prominent ribs and veins, beneath. *Footstalks* half an inch long, swelling upwards, densely hairy. *Stipulas* the same length, lanceolate, acute, downy, permanent. *Flower-stalks* axillary, three, four, or five together, scarcely half the length of the leaf, mostly three-flowered, downy. *Flowers* not unlike our common lime-tree, but with red petals half the length of the calyx. *Column* a line in height, cylindrical, smooth, with a bristly crown under the filaments. *Germen* most hairy when young, globular, at length almost naked. *Fruit* globose, red, the size of a black currant, acid and agreeable.

12. G. *tiliæfolia*. Vahl. Symb. v. 1. 35. (Microcos lateriflora; Linn. Sp. Pl. 734. Fl. Zeyl. n. 20[4]. Hamdamanias; Herm. Mus. Zeyl. 3.)—Leaves roundish, somewhat heart-shaped, serrated, slightly unequal at the base, smooth on both sides. Flower-stalks shorter than the footstalks. *Vahl.* Native of the East Indies. *Leaves* twice as large as the last, bluntly and pretty equally serrated. *Footstalks* scarcely thickened upwards, powdery at the top. *Stipulas* half-heart-shaped, hardly half so long as the footstalks. *Flower-stalks* axillary, two or three together, about the length of the stipulas. *Fruit* two-lobed, smooth. Our knowledge of this species, the only one, except n. 14, that we have not seen, is derived from Vahl, who has well distinguished it from the last, to which Murray had erroneously affixed the Linnæan synonym.

13. G. *villosa*. Leaves heart-shaped, serrated, fringed, rather unequal at the base; rough above; downy beneath. Flower-stalks solitary, as long as the footstalks. Calyx and germen very bristly. Column very short.—Gathered by Dr. Rottler on the mountains of Palamcotta in the East Indies, Nov 8, 1795. This is a *tree* with very numerous branches; the young ones downy and leafy. *Leaves*, in the flowering state, an inch and a half in diameter, heart-shaped, rounded, acute, generally unequal at the base, sharply serrated, with hairy teeth; their upper surface rugged and harsh; the under densely downy, greyish, with prominent bristly ribs and veins. *Footstalks* half an inch long, hairy. *Stipulas* lanceolate, bristly, deciduous. *Flower-stalks* at least equal to those of the leaves, axillary, solitary, three or four-flowered, very hairy or bristly, as is also the outside of the *bracteas*, and *calyx-leaves*, and especially the *germen*, which is globose, supported by a very short smooth *column*, crowned with a sort of membranous border. The *petals* are half the length of the calyx, oblong and obtuse.

14. G. *velutina*. Vahl. Symb. v. 1. 35. (Chadara velutina; Forsk. Ægypt. Arab. 106.)—Leaves oval, serrated, unequal at the base; very soft on both sides; hoary beneath. Flower-stalks about three together, as long as the footstalks, three-flowered. Gathered by Forskall in Arabia, where it is called *Nescham*. A *shrub*, whose branches and every other part are clothed with extremely short soft down. *Leaves* on very short stalks, an inch long, oval, sometimes slightly angular towards the extremity, obtuse, unequally and distantly serrated, whiter underneath, oblique or unequal at the base. *Stipulas* setaceous, deciduous. *Flowers* smaller than in *G. asiatica*, on axillary, three-cleft, short stalks, two or three-together. S.

Grewia *salvifolia*. Linn. Suppl. 409, is *Alangium decapetalum*, Lamarck Dict. v. 1. 174. Willd. Sp. Pl. v. 2. 1174.

Grewia *Microcos*. See Microcos.

Since our article Grewia was written, we have had access to the 4th volume of the *Annales du Muséum d'Hist. Nat.* in which, page 82, is an excellent Mémoire on that genus, by the celebrated Jussieu, accompanied by five plates, in which fourteen species are figured. This author describes thirty-three species, of which four are by himself esteemed doubtful. These are his *apetala*, t. 49. f. 3; *eriocarpa*, t. 51. f. 3; *celtidifolia*; and Vahl's *velutina*. There are some doubts respecting a few other species, and as he includes the genus *Microcos* among them, which we do not, the superiority of his numbers is not very great. Our's and Vahl's *glandulosa* is figured in his t. 48. f. 1. What we have taken for *hirsuta*, is his *tomentosa*, t. 49. f. 1. His *ovalifolia* appears, by the description, to be our *lævigata*, which he has at n. 16. Our *columnaris* and *villosa* seem unknown to Jussieu; at least we cannot refer them to any of his descriptions or figures.

GREWT, in *Mineralogy*, a word used by our miners to express earth, but particularly that earth found in the flat countries and in the banks of rivers, in their searches after mineral veins, which is different in colour and nature from the rest of the bank or bottom. This they always understand to have been washed off from the neighbouring hills, in the time when the shoad-stones, by which they train their new mines, were also washed down, that is, at the universal deluge: and this wherever found, proves of great use to them in these researches, as it shews which way the wash from the hill has run, and directs them how to trace the rest, and where to look for the shoad-stones with any probability of success. They generally examine the banks of rivers, where they have been worn away by land floods, in order to find these grewts, and then examine, in a straight line with the next hill, though four or five miles off; and if there be any mine there, they generally meet with shoad-stones, as tokens of it, in the way. Phil. Trans. N 69.

Grewt, in *Mining*, signifies the spar, or matrix, in which ore is found in a mineral vein; called also the gangrene, vein-stuff, deads, &c.

GREY, *Lady* Jane, in *Biography*, was the daughter of Henry Grey, marquis of Dorset, by Frances Brandon, daughter of Charles Brandon, duke of Suffolk, and Mary, queen dowager of France, and sister of Henry VIII. She was born about the year 1537, the exact date not being ascertained. She was, from a very early age, regarded as a prodigy in learning and useful acquirements. Besides the accomplishments of needle-work, beautiful hand-writing, and music, she possessed such a knowledge of the learned languages as would be surprizing in the most promising scholar of the other sex who attended to nothing else. It is recorded of her, that the learned Ascham, on paying her a visit, when she had not completed her fourteenth year, found her reading the Phædon of Plato, in Greek, while the other branches of the family were hunting. She was at this time under the tuition of Mr. Aylmer, afterwards bishop of London, and was able to write Greek with facility and eloquence, and she is said also to have acquired not only the French and Italian languages, but the Hebrew, Chaldee, and Arabic. The solidity of her judgment was equal to the readiness of her apprehension, and she discoursed upon

the moſt important topics with excellent ſenſe. With all theſe endowments, ſhe poſſeſſed that modeſty and gentleneſs which ſo much become the ſex. She imbibed from her preceptor the principles of the reformation, to which, during the remainder of a ſhort life, ſhe always ſteadily adhered. To the events of the period in which lady Jane lived, we have already referred pretty largely in the articles EDWARD VI. and DUDLEY, duke of Northumberland. When the latter ſaw that the young king's health was rapidly declining, he meditated the ſecuring of his authority, by a project no leſs daring than criminal. He propoſed to him to ſet aſide both his ſiſters from the ſucceſſion, and bequeathing the crown to lady Jane Grey, though her mother was then living. He had previouſly procured a marriage in May 1553, between this lady and his fourth ſon, lord Guilford Dudley, an amiable youth, who ſoon gained the affections of his charming bride. The act for altering the ſucceſſion was ſpeedily drawn up, and Edward died on the 6th of July of the ſame year: on the 10th of this month, lady Jane's father, now duke of Suffolk, accompanied by the duke of Northumberland, repaired to Durham-houſe, where the young couple reſided, and explained to her what had been done in her favour. She, for ſome time, reſiſted their importunities to become queen, knowing that ſhe had no real title to the ſovereignty, and having an unconquerable averſion from a public and ſplendid ſtation. At length, overcome by the aſſumed authority of her parents, and eſpecially by the entreaties of her huſband, ſhe conſented to become a queen, and was proclaimed to the city of London. Her reign was very ſhort: in nine days Mary was acknowledged as the rightful ſovereign, and lady Jane was rejoiced to return to a private ſtation: but the vindictive queen was not ſatisfied with having obtained her right, ſhe was reſolved to avenge herſelf on thoſe who had diſputed it. The duke of Northumberland was immediately beheaded; after which, the innocent lady Jane and her huſband were arraigned, tried, and convicted, and finally put to death. On the fatal morning, her huſband, who had been confined in ſeparate apartments, requeſted to be permitted to take a laſt farewell of her. This ſhe thought it beſt to decline, leſt it ſhould be the means of ſhaking their reſolution, at a moment when every exertion of fortitude was requiſite. She contented herſelf with giving him a parting token out of her window, as he was led to execution. She ſaw, with compoſure, his remains brought back, and immediately wrote three ſentences in Greek, Latin, and Engliſh, which ſhe preſented to the conſtable of the Tower. In a very ſhort time, the officers announced that ſhe muſt follow the ſteps of her deceaſed huſband. She received the ſummons with heroiſm, acknowledged that ſhe had done wrong in not rejecting the ambitious propoſals of her father, and declared her willingneſs to expiate the crime by death. This dreadful tragedy was acted Feb. 12, 1554. She was but ſeventeen years of age; to the credit of the age, ſhe was univerſally pitied, and the memory of her virtues has excited the higheſt reſpect; while the recollection of the bloody acts of the queen has been a ſubject of general and perpetual execration. Biog. Brit.

GREY, RICHARD, who flouriſhed in the 18th century, was born in the year 1693. Having received the elements of a good education, he was entered at Lincoln college, in the univerſity of Oxford, where he took his degree of M. A. in 1718. He ſoon had preferment in the church, and was at length made a prebend of St. Paul's, London. In the year 1730, he publiſhed his "Memoria Technica," or a new method of artificial memory. This work has gone through ſeven or eight editions, beſides which there have been ſeveral abridgments of it, in which the whole theory is developed, and as much of the practical part as is neceſſary in common life. (See MEMORY, *Artificial.*) In the ſame year he publiſhed "A Syſtem of Engliſh Eccleſiaſtical Law," extracted from the "Codex Juris Eccleſiaſtici Anglicani," of the biſhop of London, for the uſe of ſtudents in the univerſities who are deſigned for holy orders. This work was ſo highly eſteemed, that as a ſort of remuneration, he was, in the following year, preſented by the univerſity with the degree of doctor of divinity. About the year 1738, he publiſhed a new and eaſy method of learning Hebrew without points, &c. and in 1742, he preſented the public with "Liber Jobi in verſiculos Metrice diviſus, cum Verſione Latina Alberti Schultens, Notiſque ex ejus Commentario excerptis, &c." Dr. Grey was author of many other works; that on Job occaſioned a controverſy between Dr. Warburton and himſelf. He died in the year 1771, in his 78th year. Gen. Biog.

GREY. See GRAY.

GREY, in *Ichthyology*, an Engliſh name for a truttaceous fiſh, the SALMO *eriox* of Linnæus, (which ſee,) caught in many of the rivers of England.

Mr. Pennant believes this to be the *ſewin* or *ſhewin* of South Wales, which is very common in the neighbourhood of Carmarthen. This fiſh appears in the Eſk, in Cumberland, from July to September, and is then in ſpawn. The lower jaw grows hooked, when it is out of ſeaſon. The inhabitants of the North of England, and of South Wales, conſider this fiſh as a diſtinct ſpecies from the ſalmon.

GREY *Abbey*, in *Geography*, a ſmall town in the county of Down, Ireland, in the peninſula of Ardes; 89½ miles N. from Dublin, and 6½ from Donaghadee.

GREY *Antimony ore*. See ANTIMONY.

GREY-*Beds*, in *Mining*, ſignify in the neighbourhood of Macclesfield, in Cheſhire, an indurated ſandy loam, periſhable, called ſtone-bind in Derbyſhire, &c. and ſand-ſtone at Newcaſtle, in Northumberland, &c. See Kirwan's Geo. Eſſays, p. 306.

GREY *Cobalt ore*. See COBALT.

GREY *Copper ore*. See COPPER.

GREY *Deer*, in *Zoology*. See CERVUS *Guinenſis*.

GREY *Fly*. See GAD-*fly*.

GREY *Manganeſe ore*. See MANGANESE.

GREY-*Melting*, in the *Iron Manufacture*, is the name at the iron furnaces and founderies for the beſt kind of pig-iron. See IRON.

GREY *Stone*, in *Mineralogy*, grauſtein of Werner, a rock belonging to the neweſt fletz trap-formation. We are informed by Mr. Jameſon that it is an intimate mixture of white feldſpar and blackiſh hornblende, in which the feldſpar predominates; that it contains olivine and augite, two foſſils that do not occur in porphyry-ſlate, but which occur almoſt always in baſalt, into which the grey-ſtone is ſometimes ſeen to paſs; and that a portion of the unchanged rocks in the vicinity of Veſuvius is grey-ſtone.

If the rock thus characterized be entitled to a particular appellation, we think that, in order to prevent confuſion, a name ſhould have been choſen that was not yet applied to another mineral ſubſtance. The rock which has hitherto been called *grauſtein*, is the *Saxum metalliferum* of Born. As this differs in many reſpects from porphyry, under which name it has been mentioned by ſome writers, and as it is a rock of conſiderable importance, which contains almoſt the whole of the metals of Hungary and Tranſylvania, a ſhort account of it will not be deemed ſuperfluous in this place.

The grauſtein, or Saxum metalliferum, ſays Haidinger,

bears ſome diſtant reſemblance to the Saxon porphyry-rock: its component parts are a coarſe, grey, or blueiſh indurated clay, with much black mica; ſometimes it exhibits an admixture of feldſpar and of lithomarge, and now and then, in the neighbourhood of veins, a portion of quartz and even lime-ſtone. Its texture is by no means ſlaty or foliated, but uniformly compact; and it occurs in conſiderable ſtrata, affecting various inclination and dip. Only a ſingle inſtance of a ſlaty ſtructure is mentioned by Born. Its fracture is coarſe, granular, or earthy, and, in general, much reſembles indurated clay; but when expoſed to a ſtrong fire, it melts, without addition, into a black glaſs. There are four varieties of grauſtein, 1, with black mica; 2, with white lithomarge and black mica; 3, with white, moſtly decompoſed, feldſpar and black mica; 4, with quartz and black mica. The argillaceous baſe is moſtly grey, ſometimes greeniſh or reddiſh; the mica occurs now and then cryſtallized in four and ſix-ſided laminæ.

It is in this rock that almoſt all the metalliferous veins occur in Lower Hungary. In Schemnitz and Kremnitz it is moſtly of a light green colour, and dry clayey appearance: towards Herrengrund, Neuſohl, and the Hodritz, it changes its nature, owing to the admixture of a fat greeniſh clay, and of a conſiderable portion of ſilvery mica, which impreſſes it with a ſlaty character, approaching to that of gneiſs. The veins traverſe it with great regularity, and are of conſiderable thickneſs: the vein at Schemnitz, called Spitaler-hauptgang, is from fourteen to eighteen, and the Bieberſtollen-hauptgang from four to five fathoms thick. The principal vein-ſtones are quartz, which is often ferruginous and foliated, but at Kremnitz maſſive and white; a reddiſh-brown, iron ſhot, ſometimes auriferous jaſper, called zinnopel; ſeveral varieties of clay-ſtone and calcareous ſpar. In Kremnitz, in the Bartholomew ſhaft, ſome green and pale red fluor ſpar was found, a ſubſtance very ſcarce in Hungary and Tranſylvania. Alſo gypſum often occurs in thoſe veins, and ſelenite, with copper pyrites. Almoſt all metals are found in this grauſtein, but more particularly gold and ſilver, at Schemnitz and Kremnitz, in Hungary, Nagyag, Fuzeſh, Boitza, &c. in Tranſylvania. Copper occurs in it at the Herrengrund, near Neuſohl; lead in the Thereſa-mine at Schemnitz, at Offenbanya in Tranſylvania, &c.; tin, biſmuth, cobalt, and nickel are not found in grauſtein.

The argentiferous lead and copper ores at Fiorazzo in Tyrol, occur in a rock perfectly ſimilar to the Saxum metalliferum, or grauſtein of Hungary.

The grains of feldſpar and lithomarge in this rock are often ſeen decompoſed and deſtroyed, in which caſe the maſs adopts a ſpongy appearance; a circumſtance which has induced ſome writers to conſider grauſtein as a lava.

A more detailed account of this grauſtein, (which, as has been pointed out before, ſhould not be confounded with Werner's grauſtein,) is given in the Bergmannifcnes Journal, by profeſſor Wiedemann, who endeavours to prove that this rock-ſtone is perfectly different from porphyry, to which ſome mineralogiſts have referred it.

GREY *Weth rs*, in *Geology*, is a name by which certain large, looſe, blocks of ſtone are well known, that are ſcattered on the chalk downs of Dorſetſhire, Wiltſhire, Berkſhire, Buckinghamſhire, &c., and were ſo, in much greater quantities, in ſome earlier periods, before they had been removed by the inhabitants for building and other purpoſes. Theſe blocks of ſtone are ſome of them of immenſe length and breadth, and at Stonehenge, on Saliſbury plain, and in other ſituations, have been applied to the formation of the very ancient temples of the Druids, Cromlechs, &c. M. de Luc notices theſe grey wethers at page 307 of his Geology; and rather haſtily condemns the explanation which has been offered, to account for theſe huge and uniform looſe blocks of ſtone, *viz.* their being the remains of a ſtratum of ſtone (not *primitive* certainly) which has been waſhed away, except leaving theſe blocks as memorials of its exiſtence. The diſcoveries of Mr. William Smith, within the laſt twenty years, have ſhewn, that in numerous places where regular ſtrata are found on the chalk ſtrata, a ſand ſtratum is ſeen, having a bed of theſe ſtones in it, from eighteen inches to two feet or more thick, exactly anſwering in grain and fracture to theſe grey-wether blocks; and the fact ſeems indiſputable, that the waſhing away of the ſand and great part of the ſtratum, in an early era of our planet, has left theſe looſe blocks; ſomewhat ſimilar to what M. Cuvier and M. Brongniart obſerved at Bougwain, in the foreſts of Fontainbleau, and of Palaiſeau, in the environs of Paris, (ſee Philoſophical Magazine, vol. 35, p. 56. 116. and 117.) above the chalk; whether belonging to the ſame ſtratum or another, we will not take upon us to determine. The grey-wether blocks are of an irregular ſized grit, with a cherty texture, and are or have been found on the top edge of the chalk, throughout its whole courſe through England. An attentive traveller will nowhere approach the chalk diſtrict from the weſtward or northward, without obſerving the ſtep-ſtones and guard-ſtones at the doors and corners of houſes and lanes, the foundations of the buildings, &c. to be made of theſe blocks of ſtone, for ſeveral miles beyond the edge of the chalk, whither they have been carried by the inhabitants, and who have alſo uſed and conſumed much larger quantities of them, in their roads, in many inſtances, which has occaſioned theſe blocks to be much ſcarcer now in ſome diſtricts, than they formerly were. Between Marlborough and Calne, on the road from London to Bath, theſe grey-wether blocks are ſeen lying from about $77\frac{1}{2}$ miles to $81\frac{1}{4}$, but particularly in a ſlight vale on the north ſide of the road, at $77\frac{3}{4}$ miles, where the ſtone blocks almoſt cover the ſurface.

GREYHOUNDS, in *Aſtronomy*. See CANES *venatici*.

GREYLAG GOOSE. See ANSER and DUCK.

GREY LEAGUE, in *Geography*, the moſt conſiderable, in extent as well as population, of the three Griſon leagues. (See GRISONS.) The etymology of the word *grigia* or *grey*, which gives its name to this league, and indeed to the whole country, is extremely uncertain. Some conceive that the people of this diſtrict, being the original inhabitants of the country, were called *grey* in contradiſtinction to the more modern inhabitants, by way of alluſion to grey hairs, an emblem of antiquity. Others imagine, that the firſt authors of the revolution, which, in 1424, gave liberty to the communities in the Grey League, were dreſſed in the coarſe grey cloth of the country, and that, in commemoration of this great event, the league was called *Grey*. The appellation, however, is of high antiquity, and exiſted long before the revolution. Tacitus calls the inhabitants of this country "Rhætos Griſeos, id eſt canos;" and Ammianus Marcellinus ſtyles the diſtrict about Coire "Canos campos," or the *Grey* fields. It may be obſerved, in general, that the term "Griſons," or *grey* people, was the general name by which all the inhabitants of Rhætia were diſtinguiſhed; but as the inhabitants of the diſtrict called the Grey League firſt took arms for the purpoſe of aſſerting their independence, they naturally ſtyled themſelves the league of the people called Griſons, or the *Grey* league; while thoſe of the other two diſtricts, who afterwards formed ſimilar aſſociations, although equally known by the name of Griſons, took other appellations to diſtinguiſh themſelves from the firſt confederacy.

The territory now occupied by the Grey league was formerly

ly ſubject to the abbot of Diſentis, the counts of Werdenburgh, of Sax, of Maſox, and the baron of Retzuns. The people ſeem originally to have poſſeſſed conſiderable privileges, which were gradually undermined; till at length they became impatient of oppreſſion, and excited by the example of the neighbouring Swiſs republics, they determined to deliver themſelves from the grievous ſubjection under which they laboured. The meeting of the inſurgents was compoſed and orderly; and a ſolemn deputation was diſpatched to the reſpective ſovereigns at Truns. The deputies ſtated their grievances to the chiefs, and not only extorted redreſs, but procured a confirmation of ſeveral obſolete privileges, and the addition of many others. In conſideration of theſe conceſſions, the chiefs reſerved to themſelves certain prerogatives, which ſome of their deſcendants or ſucceſſors enjoy to this day;—a diſtinction, which is now peculiar to this league, and renders the general conſtitution in ſome reſpects more ariſtocratical than that of the two others. Theſe prerogatives conſiſt in being preſent at the annual diet of the league, and in alternately propoſing three candidates for "Landrichter," or chief of the league, one of whom is nominated by the deputies. The counts of Werdenberg being extinct, theſe prerogatives are now confined to the emperor of Germany, as baron of Retzuns, the abbot of Diſentis, and the temporary count of Sax. But as no real count of Sax now exiſts, certain communities of the Grey league ſeized the domains upon the extinction of that family, and continue to exerciſe the rights formerly enjoyed by the counts of Sax. Another diſtinction belonging to the Grey league is this. Like the other leagues, the particular diſtricts poſſeſs their courts of criminal juſtice in the laſt reſort; but in all civil cauſes above a certain value, an appeal lies to ſixteen deputies, annually aſſembled at Truns. This league has been long united with the two other Griſon leagues. See GRISONS.

This league is divided into eight high juriſdictions, which are ſub-divided into 27 communities, as follow:

	Communities.		Members of General Diet.
I. Diſentis	1.	Diſentis,	1
	2.	Tavetch.	1
II. Valley of Lugnetz	3, 4.	Lugnetz.	2
	5.	Wals.	1
III. Grub	6, 7.	Ilantz,	2
	8.	Schlowis,	1
	9.	Tenna.	1
IV. Waltenſburg	10.	Waltenſburg,	1
	11.	Lax,	1
	12.	Oberſax.	1
V. Flims	13.	Flims,	1
	14.	Retzuns and Embs,	2
	16.	Trins and Tamins.	1
VI. Rheinwald and Schams	17, 18.	Valley of Rheinwald,	2
	19, 20.	Valley of Schams.	2
VII. Heunzenberg and Tuſis	21.	Tuſis and Catzis,	1
	22.	Heunzenberg.	1
	23.	Saffien.	1
	24.	Cepina.	1
VIII. Maſox	25.	Valley of Maſox,	1
	26.	Ruffle,	1
	27.	Calanca.	1

GREYSAU, a town of Sileſia, in the principality of Neiſſe; eight miles S.E. of Neiſſe.

GREZ, a town of France, in the department of the Dyle, and chief place of a canton, in the diſtrict of Louvain. The place contains 984, and the canton 8372 inhabitants, on a territory of 160 kiliometres, in 22 communes.

GREZ-*en-Bouère*, a town of France, in the department of the Mayenne, and chief place of a canton, in the diſtrict of Chateau-Gonthier; ſeven miles E.N.E. of it. The place contains 913, and the canton 8728 inhabitants, on a territory of 257$\frac{1}{2}$ kiliometres, in 12 communes.

GREZZANO, a town of Italy, in the Veroneſe, on the road to Germany, having a remarkable bridge formed by nature, and connecting two hills; the arch is 50 feet in breadth, and 114 in height; 12 miles N. of Verona.

GRIAS, in *Botany*, is the name of an herb mentioned by Apuleius. *Steph. Theſaur.* Some take it for a kind of creſs. We cannot ſee why Linnæus adopted it for this Weſt Indian tree, except indeed that the fruit, known by the name of Anchovy Pear, is ſaid, when pickled, to be much eſteemed by the Spaniards, and therefore, as a kind of ſeaſoning, bears ſome analogy to the original *Grias*.—Linn. Gen. 266. Schreb. 354. Willd. Sp. Pl. v. 2. 1159. Swartz. Obſ. 215. Mart. Mill. Dict. v. 2. Juſſ. 257.—Claſs and order, *Polyandria Monogynia*. Nat. Ord. *Heſperideæ*, Linn. *Myrti*, Juſſ. (and not ſurely *Gutiferæ*, as Juſſieu makes it?)

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, coriaceous, rather ſmall, in four deep, rounded, equal, concave ſegments. *Cor.* Petals four, much larger than the calyx, oblong, obtuſe, concave, coriaceous, their outer edges thin and ſlightly crenate. *Stam.* Filaments numerous ("inſerted into a ſquare receptacle, united at the baſe into five ſeries;" *Swartz.*), incurved, linear; the outermoſt longeſt, half the length of the corolla; the innermoſt very ſhort; anthers terminal, ſmall, orbicular, of two cells. *Piſt.* Germen inferior, turbinate; ſtyle none; ſtigma minute, croſs-ſhaped, yellow, concealed by the incurved ſtamens. *Peric.* Drupa ovate, with eight furrows, crowned with the calyx. *Sed.* Nut ſolitary, oblong.

Eſſ. Ch. Calyx ſuperior, in four deep ſegments. Petals four. Stigma ſeſſile, croſs-ſhaped. Drupa with eight furrows. Nut ſolitary.

1. G. *cauliflora*. Linn. Sp. Pl. 732. (Calophyllum? foliis tripedalibus obovatis, floribus per caulem et ramos ſparſis; Browne Jam. 245. Palmis affinis Malus Perſica maxima, caudice non ramoſo, foliis longiſſimis, flore tetrapetalo pallide luteo, fructu ex arboris trunco prodeunte;

Sloane

G R I

Sloane Jam. v. 2. 122. t. 216, and 217, f. 1, 2.)—Native of all the hotteſt parts of the Weſt Indies, in low moiſt or watery places. Frequent in many places in Jamaica. *Sloane, Browne.*

A tall ſtraight handſome *tree*, often 50 feet high, generally with a few terminal ſimple ſhort branches. *Leaves* ſimple, on ſhort ſtalks, pendulous, two or three feet in length, ovate-oblong, entire, or ſlightly waved, tapering at the baſe, ſmooth, thin, with one rib and numerous tranſverſe parallel veins, connected by reticulations. *Flowers* the ſize of a half-crown, yellowiſh-white, fragrant, in ſeſſile cluſters ſcattered over the ſtem or branches far below the leaves, their ſtalks branched and ſcaly. They come forth in the ſpring. *Fruit* ovate, with eight furrows, as big as a large apple. Linnæus, apparently from miſunderſtanding Browne's deſcription, attributes the furrows to the nut, inſtead of the external coating.—Dr. Swartz's deſcription, accompanied by a ſpecimen, has enabled us, we truſt, to give a more correct account of the characters and affinities of this little known genus than has hitherto appeared. Its relationſhip to *Eugenia*, *Barringtonia*, &c. notwithſtanding the ſeſſile ſtigma, ſeems much more certain than to Juſſieu's *Guttiferæ*. S.

GRIASOVETZ, in *Geography*, a town of Ruſſia, and one of the five diſtricts of the province of Vologda, ſituated on a river falling into the Sukkona; 40 miles S.S.E. of Vologda. N. lat. 58° 36'. E. long. 40° 44'.

GRIBALDI, Matthew, ſurnamed *Moſa*, in *Biography*, was born at Chieri in Piedmont, and was educated for the profeſſion of the law. In 1548 he opened a ſchool of law at Padua, where he taught with great reputation. In 1553, having imbibed the principles of the reformation, he was obliged to withdraw ſecretly from that city: and having wandered about from place to place, he was at length introduced to Calvin in Geneva; but as he had incurred the ſuſpicion of being addicted to the Unitarian ſyſtem, that reformer refuſed him his ſociety unleſs he would clear himſelf of the charge; not being able to do this, he was ordered to depart from the city, and the recent fate of the excellent Servetus admoniſhed him of the danger of delay. The perſecuting Calvin predicted the calamities which would befal him, a circumſtance in which he was not likely to be miſtaken, as they were the reſult of that intolerance which he himſelf had excited. Gribaldi was received at Tubingen, where he was choſen profeſſor, till the ſpirit of perſecution impelled him to fly. He now repaired to Bern, in the neighbourhood of which he purchaſed an eſtate with the hope of ſpending his days there, but being cited before the magiſtrates to anſwer for the hereſies imputed to him, he was under the neceſſity of retracting, in order to gain his liberty. Little can be expected from ſuch kind of retractations; that of Gribaldi was not regarded as ſincere, as an evidence of which he afforded an aſylum to the perſecuted Gentilis, for which he would probably have ſuffered ſeverely, had not death interpoſed between him and his cruel perſecutors. He died in 1564 Gribaldi was accounted very eminent in his profeſſion, and a friend to juſtice. He wrote commentaries on the pandects, and other parts of the civil law. Bayle.

GRIBANE, in *Geography*, a town of Canada, on the river St. Lawrence; 30 miles N.E. of Quebec.

GRICANE, a town of Moldavia; 20 miles N. of Jaſſi.

GRICE, a term uſed by country perſons for a young wild boar.

GRICENESS, in *Geography*, a cape on the E. coaſt of the iſland of Stronſa. N. lat. 59° 1'. W. long. 2° 28'.

GRICHE, a town of Perſia, in Segeſtan; 140 miles E.N.E. of Zareng.

GRIEF. The influence of this paſſion on the body is very great, ſo as often to deſtroy all appetite and deſire of meat, either by inſpiring men with a diſreliſh for life, or by a mechanical inſtinct; becauſe food taken at ſuch a time makes but bad nouriſhment, fitter to corrupt the blood than prolong life; on which account it is aſſigned as a phyſical cauſe for the faſting practiſed among the heathens. The influence of this paſſion extends itſelf even to beaſts; which, when indiſpoſed, not only take no pains to provide themſelves food, but alſo refuſe it when laid before them. Vide Mem. Acad. Inſcript. tom. v. p. 50, ſeq. This paſſion has been found to leſſen perſpiration and urine.

GRIELUM, in *Botany*, γρίηλον, a ſynonym of the Ἱππομέλινον in Dioſcorides, a kind of wild parſley. The name ſeems to have been applied by Linnæus or the younger Burmann to the genus which now bears it, and which they ſeparated from *Geranium*, on account of the leaves, which have certainly a reſemblance to ſome umbelliferous plants, though more to the leaves of an *Artemiſia*. Linn. Gen. 578. Schreb. 311. Willd. Sp. Pl. v. 2. 771. Mart. Mill. Dict. v. 2. Lamarck. Dict. v. 3. 45. Illuſtr. t. 388. Gærtn. t. 36. (Geranium; Juſſ. 269. Cavan. Diſſ. 194.) Claſs and order, *Decandria Pentagynia*. Nat. Ord. *Gruinales*; Linn. *Gerania*. Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, in five deep, ſpreading, acute, equal, permanent ſegments; its baſe flat. *Cor.* regular, of five large, ſpreading, obovate, ſeſſile petals, attenuated at their baſe. Nectary of oblong glands, ſurrounding the germen, and united into a little crown. *Stam.* Filaments ten, thread-ſhaped, rather rigid, equal, permanent, the length of the calyx, or rather ſhorter; anthers ovate-oblong, verſatile, emarginate at each end. *Piſt.* Germens five, diſtinct, awl-ſhaped, erect, ſhorter than the ſtamens; ſtyles none, except the points of the germens; ſtigmas capitate, warty. *Peric.* Capſules five, oblong, pointed, hard. *Seeds* ſolitary? oblong.

Eſſ. Ch. Calyx deeply five-cleft. Petals five. Nectariferous glands forming a crown round the germen. Filaments permanent. Capſules five, pointed, with ſolitary ſeeds.

Obſ. Linnæus doubts whether there may not be ſome ſexual difference between different flowers, or an occaſional abortion of the piſtils. This genus is certainly very near *Geranium*, but wants the beak of the fruit, and conſequently thoſe awns of the capſules ſo remarkable in that, as well as in *Erodium* and *Pelargonium*. See Gerania.

Only one ſpecies is known,

G. *tenuifolium*. Linn. Gen. 578. Lamarck. Dict. v. 3. 45. (G. laciniatum; Gærtn, v. 1. 180. Geranium grandiflorum; Linn. Sp. Pl. 958. Cavan. Diſſ. t. 75. G. fruteſcens incanum, foliis multifidis, flore magno luteo dentato; Burm. Afr. 88. t. 34. f. 1. Ranunculo-platycarpos, foliis tenuiſſimè diſſectis, flore ingenti ſulphureo; ibid. 149. t. 53.)—Native of the Cape of Good Hope. It appears to have been formerly alive in the gardens of Holland, but we know nothing of it in thoſe of this country. The *ſtem* is ſhrubby, but diffuſe and very much branched, and clothed, like the *leaves*, with more or leſs of a white cottony down. The latter are alternate, repeatedly forked, an inch or two in length, their ſegments narrow, linear and acute. *Flowers* larger than a common mallow, yellow, on long, ſimple, ſolitary, lateral ſtalks; the petals uſually toothed, or ſlightly jagged. They are very handſome, and their colour is unuſual in this tribe.

Lamarck preſumes too much on John Burmann's accuracy when

when he ſuppoſes his two figures above cited really repreſent different plants, becauſe they expreſs ſome differences of character.

GRIEN HEAD, in *Geography*, a cape on the W. coaſt of the iſland of Barray, one of the Scots Hebrides. N. lat. 66° 59′. W. long. 7° 31′.

GRIESBACH, or GRIESPACH, a town of Bavaria; 14 miles W. of Paſſau.

GRIESKERRIE, one of the ſmaller Shetland iſlands. N. lat. 60° 32′. W. long. 0° 58′.

GRIEZ, a town of Perſia, in Segeſtan; 53 miles S.W. of Ghizni.

GRIFALCO, a town of Naples, in Calabria Ultra; four miles W. of Squillace.—Alſo, a town in the province of Otranto; 17 miles S.E. of Otranto.

GRIFFET, HENRY, in *Biography*, was born at Moulins in 1698. He was educated among the Jeſuits, in whoſe connection he remained till the abolition of the order, when he retired to Bruſſels, where he died in 1775. He publiſhed a new edition of "Father Daniel's Hiſtory of France," in 17 volumes 4to.; to this he ſubjoined learned and curious diſſertations, and the life of Lewis XIII., which occupies three of the volumes. He was author alſo of "A Treatiſe on the different kinds of Proof employed in eſtabliſhing hiſtorical Facts." This is eſteemed a ſolid and very judicious performance. He gave a new edition of Avrigny's Memoirs of Profane Hiſtory in five volumes, and publiſhed "Sermons," and other works of practical piety. Gen. Biog.

GRIFFIER, JOHN, a landſcape painter, born at Amſterdam in 1645. A pupil of Roland Roghman, to whoſe manner he did not adhere after he became acquainted with the more perfect one of A. Vandervelde and Lingelbach, though his talents were of a far inferior claſs to either of thoſe artiſts. He ſettled in England, and made views of many of the principal places, which are highly wrought, but with rather an artificial tone of colouring. His execution was minute and laboured, but his pictures are very well completed in that ſtyle. He likewiſe employed his talents in imitations of Rembrandt, Ryſdael, Polemburg, and Teniers, and ſo ſucceſsfully, that his productions are often taken for originals. He died in the 73d year of his age in 1718. He was known by the appellation of the old Griffier.

GRIFFIER, ROBERT, or the young Griffier, was a ſon of John, and practiſed the ſame profeſſion as his father, and in the ſame ſtyle. He reſided chiefly upon the continent, and produced a great number of elaborate pictures of views on the Rhine, &c. with many figures in them.

GRIFFON, GRYPHUS, γρὺψ, in *Natural Hiſtory*, the name of an imaginary bird of prey, of the eagle kind.

The ancients ſpeak fabulouſly of the griffon: they repreſent it with four legs, wings, and a beak; the upper part repreſenting an eagle, and the lower a lion: they ſuppoſe it to watch over gold-mines, hidden treaſures, &c.

The animal was conſecrated to the ſun; and the ancient painters repreſented the chariot of the ſun as drawn by griffons. M. Spanheim obſerves the ſame of thoſe of Jupiter and Nemeſis.

The griffon, in Scripture, is that ſpecies of the eagle called in Latin, *oſſifraga*, the *oſprey*; and פֶּרֶס, of the verb פָּרַס, *paras, to break*.

The griffon is frequently ſeen on ancient medals; and is ſtill borne in coat-armour.

Guillim blazons it rampant; alleging, that any very fierce animal may be ſo blazoned, as well as the lion. Sylveſter. Morgan, and others, uſe the term *ſegreiant*, inſtead of rampant.

This is alſo an ornament of architecture in conſtant uſe among the Greeks, and was copied from them, with the other elegancies of architectural enrichments, by the Romans. See SPHYNX.

GRIFFON, in *Ornithology*. See VULTUR *fulvus*.

GRIG, in *Ichthyology*, a name frequently uſed for the ſand eel, or ammodytes.

Theſe are common in the Thames, and are diſtinguiſhed from the common ſort by having a larger head, a blunter noſe, thicker ſkin, and leſs fat; and they are not ſo much eſteemed, and ſeldom exceed three or four ounces in weight.

GRIGGIO, in *Geography*, a river of Naples, which runs into the Adriatic. N. lat. 42° 12′. E. long. 14° 50′.

GRIGNAN, a town of France, in the department of the Drôme, and chief place of a canton, in the diſtrict of Montelimart, 10 miles S.S.E. of it. The place contains 1669, and the canton 8042 inhabitants, on a territory of 207½ kiliometres, in 13 communes.

GRIGNOLS, a town of France, in the department of the Dordogne, and chief place of a canton, in the diſtrict of Perigueux; 10 miles S.S.W. from it. The place contains 1014, and the canton 10,559 inhabitants, on a territory of 187½ kiliometres, in 12 communes.—Alſo, a town of France, in the department of the Gironde, and chief place of a canton, in the diſtrict of Bazas; 9 miles S.E. of it. The place contains 3160, and the canton 5000 inhabitants, on a territory of 135 kiliometres, in 10 communes.

GRIGNON, a village of France, in the neighbourhood of Paris, is rendered intereſting to the curious, and to the geologiſt in particular, for its quarries of gypſum and ſtone, which contains ſuch a multitude and variety of organic remains, that 600 different ſpecies of foſſil ſhells have been there obſerved! See Philoſophical Magazine, vol. 33, p. 314, and vol. 35, p. 118.

GRIGRI, in *Ornithology*. See RAMPHASTOS *Aracari*.

GRIGUET BAY, in *Geography*, a bay at the N.E. extremity of Newfoundland. N. lat. 51° 40′. W. long. 55° 24′.

GRILIMON, a town of Aſiatic Turkey, on the W. coaſt of Natolia. N. lat. 38° 35′. E. long. 26° 19′.

GRILLA, LA, a town of South America, in the government of the Caraccas; 50 miles S.S.W. of Merida. N. lat. 7° 22′. W. long. 70° 56′.

GRILLADE, in *Cookery*, meat broiled on the gridiron; thus called from the French *griller*, to *broil*.

The word is alſo uſed for the browning of any diſh, by rubbing a red-hot iron over it. To *grill* oyſters, is to put them into ſcollop ſhells, ſeaſon them with ſalt, pepper, and parſley ſhred, and pour their own liquor to them, covering them with grated bread, ſtewing them half an hour on the fire, and browning them with a red-hot iron. Shrimps are *grilled* after the ſame manner.

GRILLON, in *Geography*, a town of Africa, in Sierra Leone. N. lat. 10° 34′. W. long. 13 30′.

GRIMALDI, NICOLINO, in *Biography*. See NICOLINO.

GRIMALDI, GIO. FRANCESCO. See BOLOGNESE.

GRIMANI, DOMENICO, cardinal, was born at Venice in 1460. His father being procurator of St. Mark, and afterwards doge of the city, the ſon was ſoon brought into public notice, and employed by the ſtate in important offices. In 1493 he was raiſed to the purple by pope Alexander VI. He is noticed by hiſtorians on account of the piety which he diſplayed towards his father, who having been commander of a fleet, and defeated by the Turks,

was

was impriſoned and treated with great rigour. The ſon offered to take his place, which being refuſed, he attended him in priſon, and rendered him all the ſervice in his power. The ſubject of this article was an eminent patron of the fine arts: he collected a choice and valuable library, conſiſting of eight thouſand volumes in all languages, which, at his deceaſe, he bequeathed to the canons regular of St. Salvadore, in Venice. He made a fine collection of ſtatues, and other remains of antiquity, which, augmented by his nephew John, patriarch of Aquileia, was preſented by both to the republic of Venice. He was the friend and liberal patron of the great Eraſmus, and tranſlated from the Greek ſome homilies of Chryſoſtom. He died in 1523. Moreri.

GRIMAUD, in *Geography*, a town of France, in the department of the Var, and chief place of a canton, in the diſtrict of Draguignan; 12 miles S. of Frejus. The place contains 1164, and the canton 5009 inhabitants, on a territory of 327½ kiliometres, in four communes.

GRIMBALD, in *Biography*, a learned monk of St. Bertin, in France, who, during the ninth century, at the requeſt of our excellent monarch, Alfred, being ſkilful in all the liberal ſciences, particularly *muſic*, was ſent hither by Fulk, archbiſhop of Rheims, to introduce a regular method of ſtudy in our ſchools.

GRIMBERG, in *Geography*, a town of Germany, in the county of Marck; 12 miles W. of Dortmund.

GRIMBUSTER-HOLM, one of the ſmaller Orkney iſlands, near the N. coaſt of the iſland of Pomona.

GRIMM, in *Zoology*, Antilope *Grimmia*, Guinea antelope of Pennant, has ſhort, ſlender, ſtraight, ſharp-pointed horns, which are furrowed their whole length, and ſlightly annulated at the baſes; with a large lachrymal cavity under each eye, and a tuft of black hairs between the horns. This is a very elegant animal, about 18 inches high at the ſhoulders, the horns of the male about three inches long, and the females are ſaid to be hornleſs; the colour is various, being in ſome of a light bay colour, in others brown, mixed with aſh-colour, and tinged with yellow; the belly white, and the ſhort tail white beneath and black on the upper part; a black ſtripe runs down the middle of the face; under the chin is a ſmall hairy wart; the ears are large, and have three longitudinal depreſſions on the outſide; on each ſide, between the eyes and the noſe, is a large depreſſion, always moiſt, and containing a viſcid humour, which ſoon hardens and becomes black; the legs are aſh-coloured, very ſlender, and elegant, the fore-legs being adorned with a black band as far as above the knees, and having only a ſlight excreſcence inſtead of ſpurious hoofs. This animal inhabits Guinea.

GRIMMA, in *Geography*, a town of Saxony, in the circle of Leipſick, on the Mulda. It has three churches and a college. The articles of its chief trade are wood, linen, thread, beer, and flannels; 15 miles E.S.E. of Leipſick. N. lat. 51° 12′. E. long. 12° 40′.

GRIMMEN, or Grims, a town of Anterior Pomerania, 14 miles S. of Stralſund. N. lat. 54 6′. E. long. 13° 4′.

GRIMMIA, in *Botany*, was named by Ehrhart, and ſubſequently by Hedwig, in honour of Dr. John Frederick Charles Grimm, author of a methodical enumeration of the plants about Iſenach, in Upper Saxony, printed in the Nov. Act. Acad. Naturæ Curioſorum, v. 3, 4, and 5, as alſo of an account of the *Braſſica alpina*, referred by him to *Turritis*, in v. 3. Of this he ſent a drawing to Linnæus, as mentioned in the Syſt. Veg. along with a ſpecimen. Whatever his ſcientific merits may be, the writer of this can teſtify, that they are not enhanced by ſuavity of manners. Ehrh. Beitr. v. 1. 176. Hedw. Fund. v. 2. 89. Sp. Muſc. 75. Schreb. 759. Sm. Fl. Brit. 1183. Swartz. Muſc. Suec. 27. (Weiſſia; Hedw. Fund. v. 2. 90. Sp. Muſc. 64. Swartz. Muſc. Suec. 25. Bryi et Mnii ſpecies variæ; Linn.) Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Capſule ovate. Fringe ſimple, of 16 teeth, broadeſt at their baſe. Flowers terminal. Veil cylindrical.

We refer the reader to the article Dicranum for ſome remarks on the Hedwigian ſyſtem of Moſſes, which equally concern the preſent genus, diſtinguiſhed from that by having undivided, inſtead of forked, teeth in the fringe. *Grimmia*, even including *Weiſſia*, is not half ſo numerous in ſpecies as *Dicranum*; nor can they with any propriety or convenience be ſeparated, the only ſuppoſed difference being, that *Grimmia* of Hedwig has *ſome* of its male flowers axillary, while in *Weiſſia* they are all terminal, which leads to no certain technical diſtinction, any more than to a natural one, in any kinds of Moſſes. Even Mohr, by no means prone to leſſen the number of genera, unites theſe two, and in his *Index Muſci Plantarum Cryptogamicarum*, enumerates 25 ſpecies, to which indeed he ſubjoins the *Octoblepharum*, and ſome ſpecies of *Pterogonium*, regardleſs of the ſmall number of teeth in the former, and of the axillary female fructification in the latter, juſt as he unites *Bryum* and *Hypnum* together, in defiance of all natural principles.—The ſpecies of *Grimmia* in the *Flora Britannica*, are twenty-ſeven, to which two more have ſince been added in *Engliſh Botany*. A few of theſe indeed are placed by Mohr in ſome of his other genera, not adopted by us.

The general habit of *Grimmia* is not much unlike that of *Dicranum*, except ſome of the latter ſpecies, which are much branched, and have broader darker-coloured leaves than the reſt. Among theſe principally are found ſome axillary bud-ſhaped male flowers. The genus does not naturally divide itſelf into any accurately defined ſections; we muſt therefore take a general view of the leading ſpecies only.

G. *recurvata*. Hedw. Crypt. v. 1. 102. t. 38. Engl. Bot. t. 1489. (Bryum recurvatum; Dicks. Crypt. faſc. 2. 7. B. ſetaceum; Walf. in Jacq. Miſc. v. 2. 96. t. 12. f. 1.) is one of the ſmalleſt of Moſſes, the *Phaſea* excepted. It grows in barren graſſy mountainous places, and is annual, obſervable only in the ſpring. The *ſtem* is ſo ſhort as to be ſcarcely diſcernible. *Leaves* numerous, briſtle-ſhaped, bright green. *Fruit-ſtalk* ſolitary, capillary, at firſt erect, then recurved. *Capſule* olive-coloured, pear-ſhaped, ſmooth, with a little incurved lid half its own length. The minute *fringe* conſiſts of ſixteen deep-red teeth, dilated at their baſe.

G. *puſilla*, (Weiſſia puſilla; Hedw. Crypt. v. 2. 78. t. 29 A.) and *ſtriata*, Engl. Bot. t. 1988, are alſo minute ſpecies.

G. *ſchiſti*, Engl. Bot. t. 1952, is a larger and very pretty alpine ſpecies of rare occurrence.

G. *Starkeana*, Engl. Bot. t. 1490; *atro-virens*, t. 2015, not in Fl. Brit.; *lanceolata*, t. 1408; are all allied by their broader leaves, dark-colour and ſtouter habit; nor is *calcarea* (Bryum calcareum; Engl. Bot. t. 191.) unlike them, notwithſtanding its cylindrical foliage.

G. *controverſa*, t. 1367; *Dickſoni*, t. 1420; and *cirrata*, (Vaill. Paris. t. 24. f. 8.) agree in their beautiful capillary *leaves*, curled or frizzled in drying, and a peculiar elegance of form in their *capſules*.

G. *recurviroſtra*, Engl. Bot. t. 1438, is nearly allied to them in delicacy, but has broader *leaves*, and a ſhorter blunter *lid*.

G. *verticillata*, t. 1258, is remarkable for having eſcaped the

the obſervation of Haller, Hedwig, and moſt other cryptogamic botaniſts. Mohr has it not in his liſt. It is a very elegant moſs, with a branched *ſtem*, and narrow *leaves*, of a fine green, growing in ſubalpine ſprings, on a calcareous ſoil; in conſequence of which it is found incruſted with minute ſtalactitical fragments, as white as ſnow. The *fruit-ſtalks*, though at firſt terminal, become immediately lateral, in conſequence of the elongation of the branches, in this, as in other ſpecies. Linnæus adopted this plant entirely from Dillenius, and the Rev. H. Davies has communicated it to us from its original place of growth. To him alſo we are obliged for the diſcovery of G. *criſpula*, t. 2203, (Weiſſia criſpula; Hedw. Sp. Muſc. t. 12. f. 1.—6.) in Angleſea; though ſince found by other botaniſts in Ireland and Suſſex.

G. *acuta*, Engl. Bot. t. 1644, not ſo characteriſtically repreſented there as could have been wiſhed, is conſpicuous on its native mountains for its ſilky olive-coloured aſpect, and long, curved, but never criſped, ſhining *leaves*. The *fruitſtalks* only become ſpiral and twiſted by drying.

G. *inclinata*, t. 1824, is a *Swartzia*, now *Cynontodium*, of Hedwig; *Aſzelia* of Ehrhart (which is equivalent to *Weiſſia*); and *Didymodon* of Swartz and Mohr. The chief character of *Cynontodium* is that the ſtamens and piſtils are in the ſame flower, which is of no value in founding genera of Moſſes, and of *Didymodon* that the teeth are approximated in pairs, which we do not find the caſe with the preſent plant, nor does it appear to us of any generical importance, except where the teeth are 32, as in *Trichoſtomum*.

G. *het romalla*, t. 1899, otherwiſe not unlike the laſt, has the leaves curved to one ſide, like *homomalla*, t. 1900; but this has its 16 teeth approximated in pairs, an admirable ſpecific mark, but the two moſſes are otherwiſe ſo very nearly akin, that it decidedly can be no generic one.

G. *nigrita*, t. 1825, found in ſandy ground in Scotland, bears a moſt ſingular, round, dark-coloured, drooping capſule.

G. *Forſteri*, t. 2225, we are nearly perſuaded is *Mnium conoideum*, t. 1239.

G. *conoſtoma*, t. 1135, a large and handſome ſpecies, is made a genus, *Conoſtomum*, by Dr. Swartz in Schrader's New Journal, on account of the long-pointed cohering fringe; and the diſtinct habit reſembling that of *Bartramia*, confirms the meaſure. There is an antarctic ſpecies beſides.

G. *nuda*, Engl. Bot. t. 1421, (the *roſea* of ſome late foreign authors,) is known by its beautiful pink ſtalk, round capſule, and very few ſhort leaves.

G. *ſplachnoides*, t. 2164, (Splachnum longicollum; Dicks. Crypt. faſc. 4. 4. t. 10. f. 9.) is extremely remarkable for its reſemblance to a *Splachnum*, which is ſo great, that ſome very eminent judges have thought it a kind of *lusus Naturæ*; but we cannot admit the ſuppoſition.—The exotic *Weiſſia radians*, Hedw. Sp. Muſc. 73, t. 13. f. 1—4, is nearly akin to this, and no leſs like a *Splachnum* in habit.

G. *fugax*, (Weiſſia fugax; Hedw. Sp. Muſc. t. 13.) a German ſpecies of diminutive ſtature, ranges near ſome of our firſt-mentioned, as does his *microdonta*, t. 11. His *criſpula*, t. 12. f. 1—6, from Bohemia, is neareſt our *Dickſoni*.

After the above follow the more dark and broad-leaved branching ſpecies, of which G. *apocarpa*, t. 1134, is a common and characteriſtic example, not rare on trees or rocks. Its hair-pointed upper *leaves*, nearly ſeſſile *capſule*, (which is uſual in theſe,) and red *fringe* and *lid*, ſerve to identify it.—G. *Donniana*, t. 1259; *alpicola*, t. 2226; *maritima*, t. 1645; *rivularis*, t. 1345; and *ſtricta*, t. 1963, all much reſembling each other, make up the Britiſh ſpecies of this tribe. G. *plagipodia*, Hedw. Sp. Muſc. t. 15. f. 5—13, and eſpecially *cribroſa*, Hedw. Crypt. v. 3, t. 31 A, natives of Germany, are remarkable for the perforated teeth of their crimſon fringe, which in the laſt-mentioned are no leſs beautiful than curious.

GRIMNESS, in *Geography*, a cape on the E. coaſt of the iſland of South Ronaldſha. N. lat. 58° 42'. W. long. 2° 45'.

GRIMOLOW, a town of Poland, in the palatinate of Podolia; 46 miles N. N. W. of Kaminiec.

GRIMROOS, a town of New Brunſwick, on the river St. John. N. lat. 45° 50'. W. long. 66° 12'.

GRIMSAY, one of the weſtern iſlands of Scotland, ſituated between North Uiſt and Benbecula. It is a barren iſland, 2 miles long, and covered with heath. N. lat. 57° 27'. W. long. 7° 13'.

GRIMSBY, or GREAT GRIMSBY, ſo called to diſtinguiſh it from a village of the ſame name, is a borough, market, and ſea-port town, ſituated near the mouth of the Humber, in the wapentake of Bradley-Haverſtoe, in Lindſay diviſion of Lincolnſhire, England. It is one of the moſt ancient boroughs in the kingdom, was formerly rich and populous, and poſſeſſed a conſiderable ſhare of foreign commerce and internal trade. The firſt charter was granted by king John. Two members, elected by the reſident burgeſſes, have been returned to parliament ever ſince the reign of Edward I. At the ſiege of Calais, by Edward III. Grimſby ſupplied the king with eleven ſhips and 170 mariners. But the trade afterwards declined, and the harbour, which had been very commodious, became nearly choaked with mud. The ſpirit of the place has, however of late revived; the harbour has been improved, and a dock conſtructed at a great expence, by which means the trade of the port has been increaſed, and the town extended by many additional buildings. Here were formerly two pariſh churches; but that of St. Mary, which was a handſome building, and its ſteeple a good land-mark for mariners, has been long ſince taken down. The remaining church, St. James's, is a ſpacious ſtructure, built in the form of a croſs, with a tower in the centre. Originally it was of greater extent, a part of the choir having fallen down about the year 1600. The ſteeple is a beautiful ſpecimen of Engliſh pointed architecture, and appears to have ſuffered leſs from the depredations of time than other parts of the church. The alterations it has undergone at different periods by no means correſpond with the ſtyle of the original building. The civil government of the town is now veſted in a mayor, two bailiffs, twelve aldermen, and thirty-ſix burgeſſes. The mayor and bailiffs hold ſeparate courts; the former on Tueſday, the latter on Friday. Grimſby is diſtant from London 170 miles: contains 257 houſes and 1524 inhabitants; has a weekly market on Wedneſdays and two annual fairs. Here were formerly a monaſtery of Grey friars, a convent of Benedictine nuns, and a priory of Auguſtine canons; many ancient monuments, removed from theſe religious houſes, are now depoſited in St. James's church.

Grimſby had the honour of being the birth-place of that diſtinguiſhed prelate, Dr. John Whitgift, archbiſhop of Canterbury, and a zealous aſſerter of the doctrines and diſcipline of the eſtabliſhed church. He was born in 1530, and died Feb. 1603.

In the vicinity of the town are many of thoſe extraordinary fountains called Blow-wells. Theſe are deep circular pits which furniſh a continual flow of water, riſing to the ſurface of the ground but never overflowing. Beauties of England and Wales, vol. ix.

GRIMSBY-*Canal*, is a ſhort canal of very large dimenſions, leading from the Humber river to Grimſby wet docks, made

in purſuance of an act of 36 Geo. III. See our article CANAL.

GRIMSBY'S *Townſhip*, a townſhip of Upper Canada, in Lincoln county, W. of Clinton, and fronting lake Ontario.

GRIMSEL, a mountain of Switzerland, being one of the Alps which ſeparate the Vallais from the country of Berne. The aſcent of this mountain preſents the ſeveral ſhades of vegetation: in the valley and lower parts of the mountain, corn and rich meadows: then foreſts of larch and pine; next ſhort graſs, together with ſeveral ſpecies of herbs, that afford exquiſite paſture to the cattle: to theſe ſucceed the various tribes of moſſes and lichens; then bare rocks and ſnow. In the midſt of this mountain, about two miles from the top, is a ſmall plain or hollow, containing one ſolitary hovel, furniſhing accommodations for travellers, and kept by a landlord who is placed here by the canton of Berne, and reſides in it about nine months, from the firſt of March to the beginning of December. When he returns he leaves proviſions for any unfortunate wanderer who may chance to paſs this way in winter; and on both ſides of the track long poles are fixed for direction to travellers after the ſnow has fallen. In the ſummer months numerous herds of goats are kept upon theſe mountains. The ſources of the Aar are three lakes near the hovel juſt mentioned; one of theſe lakes is of a dark appearance, and its name is as melancholy as its aſpect: it is called the "lake of the dead," becauſe the dead bodies of thoſe who periſh in travelling theſe inhoſpitable regions are thrown into it.

GRIMSON, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 61° 14'. E long. 17° 6'.

GRIMSTA, a town of Sweden, in Weſt Gothland; 18 miles N. E. of Uddevalla.

GRIN, a town of Armenia; 130 miles N. E. of Erivan.—Alſo, a ſmall iſland in the Atlantic, near the W. coaſt of Africa. N. lat. 19° 29'.

GRINADIL, one of the ſmaller weſtern iſlands of Scotland, near the E. coaſt of Benbecula.

GRIND, a ſmall iſland near the coaſt of Friesland; 10 miles N. N. W. of Harlingen. N. lat. 53° 21'. E. long. 5° 13'.

GRINDAL, EDMUND, in *Biography*, was born at a village near Whitehaven, in Cumberland, in the year 1519. He diſcovered, at a very early age, a ſtrong inclination for learning, and after he had paſſed through the grammar ſchool he was ſent to Magdalen college, Cambridge, from whence he removed to Chriſt's college, and again to Pembroke Hall, where he was choſen fellow in 1538. He took his degrees, and in 1548 was appointed ſenior proctor of the univerſity, and in the following year he was elected lady Margaret's preacher at Cambridge. His learning, piety, and virtue recommended him to the notice of biſhop Ridley, who, in 1550, appointed him his chaplain, and in the following year he was collated to the precentorſhip of St. Paul's cathedral. His next promotion was to the appointment of chaplain to his majeſty, and in 1552 he was made prebendary of Weſtminſter. Upon the death of king Edward Mr. Grindal, who did not mean to abandon his principles, thought it prudent to retire into Germany, to avoid the perſecution of Mary and her cruel biſhops. He ſettled at Straſburg, where he applied with great diligence to the ſtudy of the German language, to qualify him to preach in the churches of that country. While he was on the continent he was very induſtrious in collecting authentic accounts of the lives and writings of the ſufferers in England for the Proteſtant religion, which he preſented to Mr. John Fox, who inſerted them in his "Acts and Monuments." (See FOX, JOHN.) Upon the demiſe of queen Mary, in 1558, he returned to England, and was employed with others in preparing the new liturgy, which was to be preſented to the queen's firſt parliament. He was alſo employed in ſome important miſſions, and appointed maſter of Pembroke Hall, Cambridge, in the room of Dr. Young, who refuſed to take the oaths of ſupremacy. This was in the year 1559, and in the ſame year he was nominated to the biſhopric of London, in the ſtead of Bonner; but he did not abſolutely accept it on account of ſome ſcruples of conſcience with reſpect to the habits and ceremonies to be uſed by the biſhops. Having conſulted his friend Peter Martyr, who recommended him to comply, he was conſecrated before the cloſe of the year. In 1560, biſhop Grindal, in conjunction with the archbiſhop of Canterbury, reformed the calendar for the book of Common Prayer, and ordered that the ten commandments, in Engliſh, ſhould be ſet up upon the eaſt wall of every church throughout the kingdom. In 1563 he was employed, with the archbiſhop of Canterbury and ſome civilians, in preparing a book of fixed ſtatutes for Chriſt's college, Oxford. About the ſame time he rendered an important ſervice to the Engliſh merchants at Antwerp and other places, at that period under the Spaniſh dominion, who, from repeated ill uſage, were deſirous of removing from their territories to ſome commodious place on the continent, where they might enjoy the rights of conſcience, and purſue their trade without the reſtrictions grievouſly impoſed on them by the Spaniſh government. By means of his intereſt with the queen, and his able management with the agent of the earl and counteſs of Eaſt Friezeland, he procured a licence for their eſtabliſhment at Embden, where they were ſoon ſettled to their entire ſatisfaction. In the year 1564 biſhop Grindal was admitted to the degree of doctor of divinity by the univerſity of Cambridge, who deputed Miles Coverdale to adminiſter to him the oaths, at his palace in London; and in the ſame year he received orders from the queen and archbiſhop Parker to proſecute all thoſe who did not comply with the act of Uniformity. Perſecution, however, was biſhop Grindal's ſtrange work; he endeavoured to conciliate by every method of kindneſs and perſuaſion, rather than make uſe of the ſword of the law, and when many were ſuffering cruel impriſonment, and refuſed to make any conceſſions with the hope of liberation, he interfered and obtained their releaſe. In 1568 he ſet about a ſubſcription for the relief of the perſecuted Proteſtants abroad: and in the year 1570 he was tranſlated to the archbiſhopric of York, and almoſt immediately afterwards went into Yorkſhire, where he found the charge which he had undertaken was more laborious than he expected, on account of the ſuperſtition and groſs ignorance that prevailed, and the ſcarcity of laborious clergymen, to inſtruct and reform them: but having put his hand to the plough he was determined not to ſhrink from his duty, and, with the zeal and perſeverance which he manifeſted, in a few years, he ſucceeded in introducing a favourable change into his dioceſe. Upon the death of archbiſhop Parker, Dr. Grindal was tranſlated to the ſee of Canterbury. He fell under the queen's diſpleaſure for reſiſting her wiſh in reſpect to putting down perſons who met together for religious exerciſes. He declared that he could not in conſcience, and without offence to the Majeſty of God, give his conſent in this buſineſs; and in a ſtrong letter which he addreſſed

to her majeſty, he exhorted her to remember, that ſhe was a mortal creature and accountable to God. This letter ſo enraged the queen, that ſhe ſent the worthy archbiſhop an order from the ſtar-chamber, which cauſed him to be confined to his houſe, and to be ſequeſtered from his archiepiſcopal functions for ſix months. As, however, the archbiſhop refuſed to retract, the ſequeſtration was continued, notwithſtanding a petition from the members of the convocation to have it removed, till the year 1582. At this period the venerable prelate loſt his ſight, and he took that opportunity of reſigning his dignity; but he never regained the queen's favour, becauſe he would never acknowledge that he was wrong in reſiſting her imperious commands. He died in 1583, leaving behind him a character of great learning and piety; of unblameable and exemplary manners. He was mild, generous, friendly, and affable; eaſy of acceſs even in the higheſt ſtate of exaltation. None of his writings were publiſhed excepting a ſermon, and a "Dialogue betweeen Cuſtom and Truth," printed in Fox's "Acts and Monuments." Biog. Brit.

GRINDELWALD, in *Geography*, a town, or rather village, of Switzerland, in the canton of Bern, at the foot of the Scheidec. This village, conſiſting of numerous cottages, diſperſed over the plain and upon the riſing hills, exhibits an agreeable and pictureſque ſcene, heightened by a view of the vallies of ice, which ſtretch along the ſteep ſides of the mountains in a regular curve, and are beautifully ſkirted with wood. The two vallies of ice which extend into the plain of Grindelwald are called the ſuperior and inferior Glaciers. The former lies between the Wetterhorn and the Mettenberg; the latter between the Mettenberg and the Eger-horn. The Mettenberg is the baſe of the Schreckhorn; and the Eger-horn, or Pointed Peak, borders on the valley of Grindelwald, and ſlopes gradually from barren rock to fertility and cultivation.

GRIND-MILL, or *Blade-mill*, in the *Manufactures*, is a kind of mill common in the neighbourhood of Sheffield, and other places where cutlery, edge-tools, and poliſhed ſteel articles, as fenders, &c. are manufactured: in theſe mills, a great number of large grind-ſtones are mounted on ſpindles, and, by means of ſtraps, are turned with great velocity. Water, in all the rivers and brooks near Sheffield, was formerly applied to theſe mills, but of late years ſeveral large ſteam-engines have been applied, to work additional grind-mills in the town and neighbourhood: the firſt of which was erected by the late Mr. Francis Thompſon, engineer, of Aſhover, Derbyſhire. See CUTLERY.

GRIND-STONE, *cos gyratalis*, in *Natural Hiſtory*, is a very coarſe, rugged, rough, and harſh ſtone, of a yellowiſh brown colour, compoſed of an irregular grit, cemented together by a coarſe and debaſed terrene cryſtalline matter, and intermixed with a very few glittering ſpangles of white talc; it cuts freely, but bears no poliſh; it is pervaded by water, will not ſtrike fire with ſteel, is not acted upon by acids, and burns to a deep red colour, but acquires no hardneſs. It is chiefly dug in the northern counties of England, and uſed for grind-ſtones, whence its name.

GRIND-STONES, in the *Manufactures*, are flat circular ſtones uſed for the grinding of edge tools, when ſuch are mounted on a ſpindle, and turned by a winch-handle, as is common in every part of the country; but in diſtricts where cutlery and tools are manufactured, great numbers of theſe ſtones are uſed in one building, called a grind-mill or blade-mill, and are turned by water or ſteam-engines. (See GRIND-MILL.) The ſtone ſuited to form grind-ſtones is what is denominated a ſharp grit, that is, the grains of ſand or ſilex of which it is compoſed are partly uniform in ſize, and are firmly attached to each other by a ſilicious or other very hard cement, without the interſtices between the grains being filled up, as frequently is the caſe, or nearly ſo, with the other kinds of ſand-ſtone. Grind-ſtones are of very different degrees of fineneſs, in the grains of ſilex, according to the different ſtrata whence they are obtained: the coarſeſt and beſt for heavy works, ſuch as the grinding of gun-barrels, &c. are from the firſt or mill-ſtone grit of the Derbyſhire ſtrata (ſee the ſection of theſe, in the Phil. Mag. plate 2, vol. xxxi.): others are from the third rock, the next ſtratum but two above the former: and in other counties coarſe grind-ſtones are manufactured from the coarſe grit rocks near the bottom of their different coal ſeries; for it is rather remarkable, that all the grind-ſtone quarries with which we are acquainted, are in the coal-meaſures or ſtrata where vegetable remains abound. The finer ſorts of grind-ſtones, and what are called whitening or poliſhing ſtones by the Sheffield cutlers, are from *different* rocks, in the upper part of the great Derbyſhire coal-ſeries; Mr. Whitehurſt, p. 168. of his "Inquiry," ſeems to have known, or diſtinguiſhed but two out of the 18 or 20 grit-ſtone rocks which this ſeries contains, and ſays, "the *upper* ſtratum of argillaceous ſtone is excellent for the uſe of cutlers' grinding-ſtones." Mr. Mawe's knowledge of theſe ſtrata ſeems to have been equally confined, ſee his ſection and deſcription in the "Mineralogy of Derbyſhire," p. 14. It may prove intereſting to many of our readers, to ſee the following liſt of grind-ſtone quarries, with their degrees of coarſeneſs, *viz.*

Aſhover, N.W. (hill quarry) Derbyſhire, middling.
Ayreſhire (water of Ayre) Scotland.
Beely Moor, E. of the town, Derbyſhire, coarſe.
Belper, S.E. (Hungerhill) Derbyſhire, middling.
Biddulph-Hall, N.W. of Leek, Staffordſhire, coarſe.
Bilſtone, S.E. of Wolverhampton, Staffordſhire, middling.
Bolſover, N.W. (nunnery) Derbyſhire, middling.
Bredſal Moor, N. of Derby, middling.
Brinclif-edge, S.E. of Sheffield, Yorkſhire, fine.
Buxton, N. (Corbar) Derbyſhire, fine.
Darley Moor, E. of the town, Derbyſhire, coarſe.
Gate-head fell, S. of Newcaſtle, Durham.
Gloſſop, Derbyſhire, coarſe.
Harthill, S.E. Yorkſhire, fine.
Hooton-Roberts, near Rotherham, York, middling.
Horſley, N. of Derby, fine.
Lane-top, N. of Sheffield. Yorkſhire, whitening.
Little-Eaton, N. of Derby, coarſe.
Milford, S. of Belper, Derbyſhire, coarſe.
Molecopt-hill, S. of Congleton, Cheſhire, coarſe.
Morley-Moor, N. of Derby, fine.
Norton, W. (Hemp-yard lane) Derbyſhire, fine.
Overton (Gregory) in Aſhover, Derbyſhire, coarſe.
Polefworth, S.E. of Tamworth, Warwick.
Purton, W. of Wolverhampton, Staffordſhire, fine.
Ridgeway (Lum-delph) in Eckington, Derbyſhire, fine.
Stanley, N.E. of Derby, fine.
Stanton by Dale, E. of Derbyſhire, fine.
Stanton Moor, N.E. of Winſter, Derbyſhire, coarſe.
Therberg, near Rotherham, Yorkſhire, fine.
Treton ditto. ditto. fine.
Warton, E. of Tamworth, Warwickſhire.
Wickerſley, near Rotherham, Yorkſhire, middling.
Wokes, near Barnſley, Yorkſhire.

Some of theſe quarries are very ancient; that in Aſhover is noticed in the Doomſday ſurvey, but ſince the incloſure of the pariſh it has been diſuſed. The ſale of grind-ſtones

from ſome of them, where navigations are near, are very conſiderable.

GRINDERS, Molares *dentes*. See *Molares* under the article Cranium.

GRINDING, Trituration, the act of breaking or comminuting a ſolid body, and reducing it into powder, duſt, flour, farina, or the like.

Grinding is one of the ſpecies of diſſolution. The painters' colours are ground on a marble or porphyry, either with oil or gum-water.

Some late phyſicians contend, that digeſtion is performed by grinding the food in the ſtomach. See Digestion.

Grinding is alſo uſed for rubbing or wearing off the irregular or otherwiſe redundant parts of the ſurface of a body, and reducing it to the deſtined figure, whether that be flat, concave, or the like.

The *grinding of glaſſes* is a conſiderable art, and, as ſuch, neceſſarily requires to be here inſiſted on; eſpecially that of optic glaſſes.

Method of grinding optic-glaſſes.—For convex glaſſes, the firſt object is to provide a diſh or baſon, within whoſe cavity the glaſs is to be formed.

In order to this, they take a piece of braſs, copper, iron, or wood, and form it into a ſegment of a circle, having the radius of the baſon or the diſh intended: this done, a baſon is forged by a ſmith, either of iron or copper, having its cavity exactly fitting or correſponding to the ſegment above mentioned, though ſometimes they chuſe to have the baſon caſt; in this caſe, the rules elſewhere delivered for concave mirrors are to be here obſerved. (See Mirror.) The figure of the baſon, thus roughly formed, is to be finiſhed in the pewterer's lathe, or on a ſtone mould A, *Plate* V. *Optics*, *fig.* 3, fixed to an iron axis with a pinion B C, moveable by a wheel D E, and that by a winch or handle F. The baſon being ground on the mould till it exactly fits in all parts, they take it off, and cementing it to a wooden block (loaden, if need be, with lead), ſtrew it over with fine ſifted ſand, and thus grind it over again on the mould, till all the furrows or ſcratches be quite taken away.

Laſtly, they grind large pieces of glaſs in a baſon, with find ſand between, till ſuch time as, its ſurface being well ſmoothed, there is no longer any oppoſition to the motion.

Note, the diſh is known to be perfectly finiſhed when, a hair being ſtretched over it, its ſhadow projected in the cavity, eſpecially in a camera obſcura, does not appear any way diſtorted.

The baſon finiſhed, they proceed to chooſe glaſſes for the purpoſe: in order to this, lay them on clean paper, and obſerve what colours are projected upon it; for the ſame are the colours of the glaſſes. Always ſet aſide thoſe of the darker colours, and chooſe the brighter; but as the whiteſt and brighteſt have uſually veins, and beſides, in tract of time, by the humidity of the air, are apt to ruſt and loſe their poliſh; for this reaſon Huygens recommends thoſe a little yellowiſh, reddiſh, or greeniſh; Hevelius the blueiſh. A glaſs is found to be free from bubbles, ſands, veins, knots, and ſpires, by holding it to the ſun, and receiving the rays through it on a white paper; for the flaws above mentioned will each project a ſhadow upon it.

If, inſtead of lenticular, or at leaſt ſpherical glaſſes, you make uſe of plate-glaſs, it muſt be divided and cut with a diamond into ſquares; and if it be too thick to break otherwiſe, you may do it by laying it on a table covered with cloth, in ſuch manner as that the ſide or part to be ſevered hang over the edge: for, being ſtruck with an iron inſtrument, in this ſituation, it eaſily breaks in the direction of the line drawn by the diamond. Having thus got a ſquare piece, deſcribe two concentric circles upon it with a pair of compaſſes, one of whoſe legs carries a diamond: the diameter of the inner circle to be equal to the breadth of the intended lens, and that of the outer ſomewhat more; and break off the corners, as above directed, and the leſſer inequalities take off on a grind-ſtone, or the like. Examine now whether the piece of glaſs be every where equally thick; if it be not, reduce it to ſuch equality by grinding it on an iron plate with ſand and water. Laſtly, glue or cement the glaſs thus prepared to a wooden handle N M O, *fig.* 4. with a cement made of pitch and a fourth part of reſin, or one part of wax and eleven of colophony: care being taken that the baſe or bottom of the handle N O be equal to the glaſs, and that the centre of the glaſs and handle meet together. Smaller lenſes, as thoſe uſed for microſcopes, are fixed on with ſealing-wax.

Now, to grind the glaſs, and bring it to the convexity required, ſmear over the diſh equally with fine ſifted ſand moiſtened with water; then taking the handle with the glaſs on it, work it on the baſon, ſometimes this way, and ſometimes that, to prevent the form of the baſon from being diſturbed, never leaning too hard upon it. When the glaſs has got the figure of the baſon, clean it well of all the ſand and filth adhering, and ſprinkle the baſon over with emery moiſtened in water, grinding the glaſs thereon till all the roughneſs and inequalities are taken away: after this, the fine ſand uſed in hour-glaſſes may be of ſervice, applied and uſed as before; remembering to take out the ſand, when too much worn, and ſubſtitute new in its ſtead. Some, in lieu of this, chooſe ſeveral ſorts of emery, each finer than the other, or even the power of flint calcined and pounded. Laſtly, grind the ſame glaſs in another baſon or diſh, which is a ſegment of a leſſer ſphere, making uſe of the like ſand as before, till it has got a pretty high rim or margin all around. Becauſe the preſſion is not here determined accurately enough upon the middle of the glaſs, by the mere guidance of the hand, ſome have choſen to make uſe of the following machine, eſpecially for grinding object-glaſſes.

Fix the diſh H I, *fig.* 5. on a horizontal table; exactly over its centre let the aperture D be, through which paſs an iron arm five or ſix inches long, faſtened to the ſtaff A B: let the other extreme of the ſtaff be fitted into a hole cut in the diſh, and faſtened therein. Now to grind the glaſs inſtead of the diſh, take hold of the ſaid ſtaff, and work with ſand, &c. as before.

Huygens tells us, that he always uſed firſt a coarſe emery, then a finer powder of the ſame, which would be fifty ſeconds in ſinking to the bottom of a veſſel of water, putting in freſh every half or quarter of an hour: ſometimes too, he uſed emery of fifty ſeconds, for three quarters of an hour; then emery of four hundred ſeconds, for four-fifths of an hour; and laſtly, emery of forty-five minutes, for a quarter of an hour. The ſame effect is had from powder of flints, broken in an iron mortar, mixed with water, and ſtirred ſometimes with a wooden ſpatula, taking the powder as it precipitates in ſome certain time to the bottom of the veſſel, by decanting the water. What remains is to poliſh the glaſs.

For a more particular account of the method of grinding and poliſhing glaſſes for teleſcopes, extracted from Mr. Huygens and other authors, by Mr. Molyneux, and comprehending the method of making and poliſhing the tools, of chooſing the glaſs, of preparing the glaſſes before they can be ground and poliſhed, of grinding the glaſſes, and of

giving

giving them the laſt and fineſt poliſh, we muſt refer to Smith's Optics, book iii. chap. i. paſſim.

The late ingenious Mr. James Short, in a paper left with the Royal Society, to be opened and printed after his death, gives the following directions for working object-glaſſes of refracting teleſcopes truly ſpherical.

Prepare two plates or tools, of braſs, the one convex, and the other concave, being both portions of a ſphere of the ſame radius as the focal length of the object-glaſs you want to have, or rather of a radius ſomewhat longer than the focal length you want, for a dioptrical reaſon; let theſe plates or tools be between two and three times the breadth of the object-glaſs deſired; or, in long focal lengths, twice the breadth will be ſufficient: let theſe tools be of a ſufficient thickneſs in proportion to their breadth or diameter, and let them be ground with fine emery exactly true to one another, working them alternately, the one above the other, to preſerve the ſame focal length; or, if it is deſired longer, you muſt work the convex above the concave; or, if deſired ſhorter, you muſt grind the concave above the convex.

After this, you prepare another braſs plate or tool, of the ſame breadth and thickneſs as the two former, and of the ſame radius of concavity: its being truly turned on a lathe will be ſufficient for this purpoſe; which tool is to ſerve afterwards for the poliſhing of the two ſurfaces of your object-glaſs, and therefore called the poliſhing tool.

Prepare a piece of ſtraw-coloured glaſs, of the plate-glaſs kind, of the proper diameter for the object-glaſs you deſire, which ought always to be broader than the proper aperture for that length; let this piece of glaſs be ground flat, in another tool, on both ſides and as nearly parallel as may be, and ſomewhat poliſhed, in order to diſcover whether there are any veins or flaws in the glaſs. When you are ſatisfied of the goodneſs of the glaſs, you are then to prepare a handle to faſten your glaſs to. Great care muſt be taken in this, for fear of bending your glaſs by the handle: Mr. Short adviſes to take a flat piece of braſs, or rather of the concavity of the ſphere, to which the glaſs is to be ground; this piece of braſs ſhould not be thicker than two-thirds of the thickneſs of the glaſs, of a circular form, leſs in breadth ſomewhat than the glaſs itſelf, and having ſides of the ſame form, at right angles to the flat piece of braſs, and theſe ſides ought to be of ſuch a ſhape as that the fingers may eaſily apply to it in working, and theſe ſides ſhould be as low as may conveniently be, and no thicker than about two-thirds of the glaſs. This handle is to be faſtened to the glaſs, by warming the glaſs and handle gently before a fire, and laying ſome pitch upon the glaſs thus warmed, till it becomes ſoft like melted wax; and then laying your braſs handle, a little heated, on the pitch, you preſs it a little, till you are ſure there is nothing between the glaſs and the handle but pitch; you then lay down the glaſs and handle upon ſomething flat, taking care that the handle is in the middle of the glaſs till it is entirely cold. It is very material to know, that the pitch, to be uſed for faſtening the handle to the glaſs, muſt be ſoft pitch, that has never been uſed nor melted; for any other pitch will infallibly bend the glaſs.

You then grind your glaſs in the concave tool with emery, and give it the proper figure and ſmoothing for the laſt poliſh, in the common manner.

In order to give your glaſs the laſt poliſh, which is the moſt difficult part of the whole work, you are to prepare ſome pitch for covering the before-mentioned poliſhing concave tool, which is done in this manner: take ſome pitch, and melt it in an iron ladle, and let it boil for a quarter of an hour or thereabouts; by this boiling, the pitch, when cold, will become hard and brittle: or you may ſhorten this operation, by melting equal quantities of pitch and roſin, and then there is no occaſion to let it boil ſo long. Your pitch being thus prepared, you again melt it, and take it off the fire, and let it ſtand till the pitch becomes pretty cold, or of a thickiſh conſiſtence; and having warmed the poliſhing tool a little, to make the pitch ſtick to it, you pour out of the ladle upon the poliſhing tool as much pitch as you judge will cover the whole tool, when ſpread out, to about the thickneſs of one-eighth of an inch; you then invert this tool with the pitch upon it, and preſs it upon the convex tool, which muſt be quite dry, clean, and cold, in order to give it the figure of the convex tool: in caſe it has not ſpread out ſo as to cover the whole ſurface of the poliſhing tool, you may warm the pitch by holding it before the fire, and preſſing it upon the convex tool, as before, till it has entirely covered the ſurface of the poliſhing tool; you then plunge it into cold water, till the braſs is quite cold.

N. B. In order to know if your pitch is hard enough, you preſs the edge of the nail of your thumb upon it, and if it receives an impreſſion, the pitch is not hard enough.

You then proceed to prepare this poliſhing tool, for the laſt poliſh of your glaſs, by grinding this poliſhing tool upon the convex tool with pretty coarſe emery, and a ſmall quantity of water, in the common way that tools are ground one upon another; but this muſt be done only for a ſmall ſpace of time, and the poliſhing tool muſt have no other preſſure than its own weight, for fear of ſome of the emery ſticking in the pitch, and you muſt never allow the emery to grow dry: when you have ground the pitch, ſo as to be all over of the ſame colour, you then waſh the pitch from all the emery with a bruſh and clean water; after this, you take a bottle of water, and, holding the pitch tool in a ſloping poſition, you pour water out of the bottle ſo as to fall upon every part of its ſurface.

You then place the poliſhing tool in a horizontal poſition, and you put upon it ſome putty, waſhed from all its gritty particles, but it need not be the fineſt waſhed, and you put a good deal of water upon your poliſhing tool, mixing the putty and it together, and you poliſh your glaſs upon this pitch-poliſher in the common manner of poliſhing glaſſes.

After you have poliſhed your glaſs about ten minutes, you again grind your poliſher upon the convex tool with emery, as before, for fear the pitch has, by working, loſt any of its proper figure; and the oftener you do this, the truer will be the figures of your glaſs; and in this manner you proceed till the glaſs is quite poliſhed.

You then take your glaſs off its handle, by holding it before the fire, till it is ſo warm that you can ſlide the handle off the glaſs; and whilſt the glaſs is warm, you take off as much of the pitch as you can with the ſharp edge of a knife; you then lay the glaſs down to cool, and when quite cold, you drop ſome ſpirits of wine upon it; and this, with a cloth, will wipe off the reſt of the pitch.

You then examine the centre of the ſurfaces of your glaſs; and if it lies to one ſide of the centre of your glaſs, mark that place with a ſpot of ink, and then put on your handle as before, upon the ſide that is now poliſhed, with its centre over the ſpot of ink, and grind your glaſs as before, till the circular remaining part of the glaſs to be ground is as much diſtant from the centre of the glaſs on the other ſide from the ſpot as the ſpot was from the centre of your glaſs; you then, by heat, return your handle to the centre of the glaſs, and proceed to grind and poliſh this ſide of the glaſs as before.

N. B. The concave and convex tools ſhould be ground with fine emery, after you have done one ſide of your glaſs; for

for the oftener theſe are ground together, you will be the more ſure of having your figure true. Phil. Tranſ. vol. lviii. p. 507, &c.

Method of Grinding, &c. the ſpecula of reflecting tel'ſcopes.—The method generally followed by workmen is that propoſed by Meſſrs. Molyneux and Hadley, and publiſhed in Dr. Smith's Optics; this has been lately improved, in a very conſiderable degree, by Mr. Mudge, whoſe directions, founded on accurate experiments, and practiſed with ſucceſs in the conſtruction of teleſcopes, we ſhall adopt wherever they differ from thoſe that occur in the book juſt cited. For making the gages, take a long pole of fir, deal, or any wood, of a little more than double the length of the inſtrument intended, and ſtrike through each end of it two ſmall ſteel points, and by one of them hang it up perpendicularly againſt a wall; then take two pieces of thin plate-braſs, well hammered, a little thicker than a ſixpence, which may be about an inch and a half broad, and let their length be in proportion to the diameter of the ſpeculum as three to two; ſo that if the ſpeculum be eight inches diameter, theſe may be about twelve. Fix each of theſe ſtrongly with rivets between two thin pieces of wainſcot, ſo that a little more than a quarter of an inch in the breadth may ſtand out from between the boards. Then fix up theſe pieces horizontally againſt the wall under your pole, and therewith, as with a beam-compaſs, ſtrike an arch upon each of them; then file each of them with a ſmooth file to the arch ſtruck, ſo as one may be a convex and the other a concave arch of the ſame circle. Theſe braſſes are the gages to keep the ſpeculum, and the tools on which it is ground, always to the ſame ſphere: and that they may be, therefore, perfectly true to each other, it is neceſſary to grind them with fine emery one againſt the other, laying them on a flat table for that purpoſe, and fixing one of them to the table. When the gages are perfectly true, let a piece of wood be turned about two-tenths of an inch broader than the intended ſpeculum, which it is beſt to caſt in no caſe leſs than two-tenths of an inch thick; and for ſpecula of ſix, eight, or ten inches broad, this ſhould be at leaſt three or four-tenths thick when finiſhed. This board being turned, take ſome common pewter, and mix with it about one-tenth of regulus of antimony, and with that wooden pattern, caſt one of this pewter, which will be conſiderably harder than common pewter. Let this pewter pattern be truly turned in a lathe, and examined by means of the gages before-mentioned, as a pattern for caſting the ſpecula themſelves; and take care, when it is turned, that it be at leaſt one-twentieth of an inch thicker, and about one-tenth of an inch broader than the ſpeculum intended to be caſt from it. The manner of making the moulds for caſting is now to be explained, and will ſerve for a direction as well for caſting this pewter pattern, as afterwards for caſting thereby the ſpeculum itſelf. The flaſks ſhould be of iron, and at leaſt two inches wider every way than the ſpeculum intended. In each flaſk there ſhould be the thickneſs at leaſt of one inch of ſand. The caſting-ſand which the common founders uſe will anſwer the purpoſe as well as any; and any ſand will do which is naturally mixed with a ſmall proportion of clay, to make it ſtick. The ſand ſhould be as little wet as may be, and well beaten, but not too hard. The ingates ſhould be cut ſo as to let the metal flow in, in four or five ſtreams, over the whole upper part of the mould; otherwiſe, whatever pores happen in the metal will not be ſo equally diſperſed as they ſhould be over the whole face of the metal, theſe pores generally falling near the ingate ſtreams. Let the flaſks dry in the ſun for ſome hours, or near a very gentle fire, otherwiſe they will warp, and give the ſpeculum, when caſt, a wrong figure: for, beſides ſaving the trouble in grinding, it is beſt, on many accounts, to have the ſpeculum caſt of a true figure; and for this reaſon it is beſt to caſt it from a hard pewter pattern, and not from a wooden one, as founders uſually caſt.

For the compoſition of the metal and manner of caſting it, ſee SPECULUM. When the metal is caſt, the next buſineſs is to grind and poliſh it, for which, ſays Mr. Mudge, four tools are all that are neceſſary, *viz.* 1. The rough-grinder, for working all the rough face of the metal: this is beſt made of lead, ſtiffened with about a fifth or ſixth part of tin; it ſhould be at leaſt a third more in diameter than the metal which is to be ground; and for one of any ſize, not leſs than an inch thick. It may be cemented on a block of wood, in order to raiſe it higher from the bench.

This leaden tool being caſt, muſt be fixed in the lathe, and turned as true as poſſible by the gage to the figure of the intended ſpeculum, making a hole in the middle, as a lodgment for the emery, of about an inch diameter, for a metal of four inches: when this is done, deep grooves muſt be cut acroſs its ſurface with a graver, in the manner repreſented in *Plate* V. *Optics*, *fig.* 6; theſe grooves will ſerve to lodge the emery, and by their means the tool will cut much faſter. Any kind of low handle, fixed on the back of the metal with ſoft cement, will be ſufficient; but it ſhould cover two-thirds of its back, to prevent its bending.

2. The next tool is the convex braſs-grinder, on which the metal is to receive its ſpherical figure. In order to form this tool, procure a round ſtout piece of Hamburgh braſs, at moſt a ſixth part larger than the metal to be poliſhed; and let it be well hammered into a degree of convexity, by the aſſiſtance of the gage, ſuitable to the intended ſpeculum: then ſcrape and clean the concave ſide ſo thoroughly, that it may be well tinned all over; then caſt upon it, after it has been preſſed a proper depth into the ſand, the former compoſition of tin and lead in ſuch a quantity, that it may, for a ſpeculum of four inches diameter, be at leaſt an inch and a half thick, and with a baſe conſiderably broader than the top, in order that they may ſtand firmly upon the bench in the manner hereafter to be deſcribed. This being done, it muſt be fixed and turned in the lathe with great care, and of ſuch a convexity as exactly to ſuit the concave gage. This tool muſt have a hole, ſomewhat leſs than that in the metal to be worked upon it, in the middle, quite through to the bottom. When it is finiſhed off in the lathe, its diameter ſhould be one-eighth wider than the metal.

The 3d tool is the bed of hones, the uſe of which is to perfect the ſpherical figure, and to give the metal a fine ſmooth face. See *Bed of* HONES.

The 4th and laſt tool is the bruiſer, with which both the braſs-grinder and the hones are to be formed; this tool ſhould be made of thick ſtout braſs, perfectly ſound, about a quarter of an inch thick, and hammered as near to the gage as poſſible; it ſhould be then ſcraped, cleaned, and tinned on the convex ſide, as the ſecond tool was on the concave, and the ſame thickneſs of lead and tin caſt upon it. This ſhould be as broad at bottom as at top; and when it is fixed in the lathe, and turned off concave to the convex gage with accuracy, the diameter ought to be of a middle ſize between the hones and the poliſher or braſs grinder, which is uſed for this purpoſe. Having with the lathe roughly formed the convex braſs grinder, the bed of hones, and the concave bruiſer, the convex and concave braſs tools and the metal muſt be wrought alternately and reciprocally upon each other with fine emery and water, ſo as to keep them to the ſame figure as nearly as poſſible, in order to which ſome waſhed emery muſt be procured, by putting it into a bottle,

half filling the bottle with water, and ſhaking the mixture; ſo that the coarſeſt of the emery will ſubſide to the bottom firſt, and the fineſt remain at the top: when freſh emery is laid on the tools, it is beſt done by gently ſhaking the bottle, and pouring out a ſmall quantity of the turbid mixture. The next operation is to grind the braſs convex tool with the bruiſer upon it, which is continued for about a quarter of an hour, and then the convex tool is wrought upon the bruiſer in the ſame manner. When theſe have been wrought on each other, occaſionally adding freſh emery, till the veſtiges of the turning tool are got out and both brought nearly to a figure, the ſame form muſt be given to the metal, by grinding it upon the braſs tool with the ſame kind of emery; taking care, however, by working the two former tools frequently together, to keep all three exactly in the ſame curve. The beſt kind of handle for the metal is made of lead, a little more than double its thickneſs, and ſomewhat leſs in diameter, of about three pounds weight, with a hole in the middle, a little larger than that in the metal: the handle ſhould be cemented on with pitch. The upper edge of this weight muſt be rounded off, that the fingers may not be hurt, and a groove, about the ſize of the little finger, be turned round juſt below it, for the more conveniently holding and taking the metal off the tools. When the bruiſer, braſs tool, and metal, are all brought to the ſame figure, and have a good ſurface, the next part of the proceſs is to give a correct ſpherical figure and a fine face to the metal, upon the hones; theſe, however, ſhould be covered with water for at leaſt an hour before they are uſed, otherwiſe they will be liable to alter their figure; and they muſt be never ſuffered to grow dry whilſt they are in uſe, for the ſame reaſon.

In order to give a proper figure to the hones, correſponding to that of the braſs tool, bruiſer, and metal, when they are fixed down to the block, ſome common flour emery, unwaſhed, with a good deal of water muſt be put upon them, and the bruiſer being placed upon the hones, and rubbed over them with a few ſtrokes and a light hand, the inequalities of the ſtone will be ſoon worn off, the mud that is generated being waſhed away, every quarter of a minute, with a great deal of water. As ſoon as the hones have received the general figure of the bruiſer, and all the turning ſtrokes are worn out from them, the emery muſt be carefully waſhed off, and cleared from the joints with a bruſh under a ſtream of water. The bruiſer and metal muſt be likewiſe cleared in the ſame manner. The hones being fixed down to the block, the bruiſer muſt be worked upon them with very cautious, regular, ſhort ſtrokes, forward and backward, to the right and left, turning the axis of the bruiſer in the hand while you move round the hones, by ſhifting your poſition, and walking round the block. The manner of conducting this operation is minutely deſcribed by Mr. Mudge. The metal may then be rubbed upon the hones in the ſame cautious manner, occaſionally rubbing the bruiſer upon the hones, in order to ſharpen them. When in this way the hone pavement has given a fine face and true figure to the metal, you may proceed to try the metal and judge of its figure, by waſhing the hone-pavement quite clean; then putting the metal upon the centre of it, and giving two or three light ſtrokes round and round only, without carrying the edges of the metal much over the hones; this will take out the order of ſtraight ſtrokes; then having again waſhed the hones and placed the ſpeculum upon their centre, with gentle preſſure, ſlide it towards you till its edge be brought a little over that of the hones; then carry it quite acroſs the diameter as far as the other ſide, and having given the metal a light ſtroke or two in this direction, take it off the tool. The metal being wiped quite dry, place it upon a table at a little diſtance from a window; ſtand as near the window, at ſome diſtance from the metal, and looking obliquely on its ſurface, turn it round its axis, and you will ſee at every half turn the grain given by the laſt croſs ſtrokes flaſh upon your eye at once over the whole face of the metal. This is a certain proof of a true ſpherical figure.

The laſt operation is that of poliſhing the ſpeculum, and this is the moſt difficult and eſſential part of the whole proceſs. Mr. Mudge, having made ſome ſtrictures on the method of Meſſrs. Hadley and Molyneux, generally followed, deſcribes at large that which he has diſcovered after a number of trials, both of giving a correct parabolic figure and an exquiſite poliſh at the ſame time. Availing himſelf of the manner of poliſhing with pitch practiſed by ſir Iſaac Newton, and mentioned in his Optics, he formed his poliſher by coating the braſs convex tool equally with pitch, which ſhould be neither very hard and reſinous nor too ſoft, about the thickneſs of a ſhilling, and by applying the bruiſer to it, gave the pitch upon the poliſher a fine ſurface and the true form of the bruiſer. He then divided the leaden weight upon the back of the metal into eight parts, by ſtrokes on the ſurface of the lead, which are marked with the numbers 1, 2, 3, 4, &c. in order to diſtinguiſh and regulate the turns of the metal. He alſo put half an ounce of putty into an ounce phial, and filled it two-thirds with water; and having ſhaken the whole, let the putty ſubſide, and ſtopped the bottle with a cork: the other appendages of his apparatus are a ſmall-ſized camel's hair bruſh in a tea-cup with a little water, a piece of dry clean ſoap in a gally-pot, and a ſoft piece of ſponge. Theſe, as well as the metal, bruiſer, and poliſher, ſhould be conſtantly covered from duſt.

The poliſher being fixed down, is bruſhed over with the camel's hair bruſh, after it has been wetted and rubbed a little over the ſoap; then the bruiſer is worked lightly upon it, till it has acquired a good face and is fit for the metal. Then, having ſhaken up the putty in the phial, and touched the poliſher in five or ſix places with the cork wetted with that and the water, the bruiſer is placed upon the tool, and a few ſtrokes given to it upon the putty, in order to rub down any gritty particles: after which, having removed it, the metal is worked lightly upon the poliſher round and round, carrying the edges of the ſpeculum, however, not quite half an inch over the edge of the tool, and now and then with a croſs ſtroke. The putty is repeatedly applied in the ſame manner, and wrought into the pitch in the courſe of the operation; and if the bruiſer be apt to ſtick, and does not ſlide ſmoothly upon the pitch, the ſurface of either tool may be occaſionally bruſhed over with the ſoap and water. After ſome continuance of this proceſs, the pitch is well defended by the coating of the putty, and the metal, preſſed only by its own weight and that of the handle, and occaſionally moiſtened, moves over it with a more uniform and regular friction. When the poliſh of the metal nearly reaches the edge, the round ſtrokes muſt be gradually altered for the ſhort and ſtraight ones. When this has been done for ſome time, in the manner minutely deſcribed by Mr. Mudge, the metal will begin to move ſtiffly as the friction increaſes, and the ſpeculum poliſhes very beautifully and ſpeedily, and the whole ſurface of the poliſhing tool will be equally covered over with a fine metallic bronze. As the metal wears much, its ſurface muſt be now and then cleaned with a piece of ſhammy leather, and the poliſher likewiſe with a ſoft piece of wet ſponge. You will now be able to

judge

judge of the perfect ſpherical figure of the metal and tool, when there is a perfect correſpondence between the ſurfaces, by the fine equable feel there is in working, which is totally free from all jerks and inequalities. Having proceeded thus far, you may put the laſt finiſhing to this figure of the metal by bold croſs ſtrokes, only three or four in the direction of each of the eight diameters, turning the metal at the ſame time: this muſt be done quickly; for, if the tool be ſuffered to grow quite dry, you will never be able, with all your force, to ſeparate that and the metal, without deſtroying the poliſher by heat. The metal will now have a beautiful poliſh, and a true ſpherical figure, but will by no means make a ſharp diſtinct image in the teleſcope; for the ſpeculum will not be found to make parallel rays converge without great aberration: and, indeed, the deviation will be ſo great, as to be very ſenſibly perceived by a great indiſtinctneſs in the image.

Suppoſing then the metal to be now truly ſpherical, ſtop the hole in the poliſher, by forcing a cork into it underneath, about an inch, ſo that it do not reach quite to the ſurface; and having waſhed off any mud that may be on the ſurface of the tool with a wet ſoft piece of ſponge, whilſt the ſurface of it is a little moiſt, place the centre of the metal upon the middle of the poliſher; then having, with the wet bruſh, lodged as much water round the edge of the metal as the projecting edge will hold, fill the whole of the metal and its handle with water, to prevent the evaporation of the moiſture, and the conſequent adheſion between the ſpeculum and poliſher, and let the whole reſt in this ſtate for two or three hours: this will produce an intimate contact between the two, and by parting with any degree of warmth they may have acquired by the nearneſs of the operator, they will become perfectly cold together. By this time you may puſh out the cork from the poliſher to diſcharge the water, and give the metal the parabolic figure, in the following manner: move the metal gently and ſlowly at firſt, a very little round the centre of the poliſher, then increaſing by degrees the diameter of theſe ſtrokes, and turning the metal frequently round its axis, give it a larger circular motion, without any preſſure, but its own weight: this manner of working may ſafely be continued about two minutes, moving yourſelf, as uſual, round the block, and carrying the round ſtrokes, in their increaſed and largeſt ſtate, not more than will move the edge of the metal half an inch or five eighths over the tool. The ſpeculum muſt not all this while be taken off from the poliſher, and conſequently no freſh putty can be added. It will not be ſafe to continue this motion longer than the time above-mentioned; for if the parabolic tendency be carried in the leaſt too far, it will be impoſſible to recover a true figure of that kind, but by going through the whole proceſs for the ſpherical one in the manner before deſcribed, by the croſs-ſtrokes upon the poliſher, which takes a great deal of time.

In order to try the true figure of the ſpeculum, place it in the teleſcope for which it is intended, and uſe the inſtrument as a kind of microſcope, moving the object to ſuch a diſtance that the rays may be nearly parallel. At about twenty yards a watch-paper, or ſome ſuch object, on which there are ſome very fine hair-ſtrokes of a graver, is fixed up. The lead muſt be taken off from the ſpeculum, the ſpeculum placed on the cell of the tube, and the inſtrument directed to the object; make an annular kind of diaphragm with card-paper, ſo as to cover a circular portion of the middle part of the metal between the hole and the circumference, equal in breadth to about an eighth part of the diameter of the ſpeculum; this paper ring ſhould be fixed in the mouth of the teleſcope, and remain ſo during the whole experiment, for the part of the metal covered by it is ſuppoſed to be perfect, and therefore unemployed.

There muſt likewiſe be two other circular pieces of card-paper cut out, of ſuch ſizes, that one may cover the centre of the metal by completely filling the hole in the laſt deſcribed annular piece; and the other, ſuch a round piece as ſhall exactly fit into the tube, and ſo broad, as that the inner edge may juſt touch the outward circumference of the middle annular piece. It would be convenient to have theſe two laſt pieces ſo fixed to an axis, that they may be put in their places or removed from thence ſo eaſily as not to diſplace or ſhake the inſtrument. All theſe pieces therefore together will completely ſhut up the mouth of the teleſcope.

Let the round piece which covers the centre of the metal, or that which has no hole in it, be removed; and, by a nice adjuſtment of the ſcrew, let the image (which is now formed by the centre of the mirror) be made as ſharp and diſtinct as poſſible. This being done, every thing elſe remaining at reſt, replace the central piece, and remove the outſide annular one, by which means the circumference only of the ſpeculum will be expoſed, and the image now formed will be from the rays reflected from the outſide of the metal. If there be no occaſion to move the ſcrew and little metal, and the two images formed by theſe two portions of the metal be perfectly ſharp and equally diſtinct, the ſpeculum is perfect, and of the true parabolic curve; or at leaſt the errors of the great and little ſpeculum, if there be any, are corrected by each other.

If, on the contrary, under the laſt circumſtances, the image from the outſide of the metal ſhould not be diſtinct, and it ſhould become neceſſary, in order to make it ſo, that the little ſpeculum be brought nearer, it is plain that the metal is not yet brought to the parabolic figure; but if, on the other hand, in order to procure diſtinctneſs, you be obliged to move the little ſpeculum farther off, then the figure of the great ſpeculum has been carried beyond the parabolic, and hath aſſumed an hyperbolic form. When the latter is the caſe, the circular figure of the metal muſt be recovered (after having fixed on the handle with ſoft pitch) by bold croſs ſtrokes upon the poliſher, finiſhing it again in the manner above deſcribed. If the ſpeculum be not yet brought to the parabolic form, it muſt cautiouſly have a few more round ſtrokes upon the poliſher: indeed a very few of them, in the manner before deſcribed, make in effect a greater difference in the ſpeculum than would be at firſt imagined. If a metal of a true ſpherical figure were to be tried in the above-mentioned manner in the teleſcope (which Mr. Mudge has frequently done), the difference of the foci of the two ſegments of the metal would be ſo conſiderable, as to require two or three turns of the ſcrew to adjuſt them; ſo very great is the aberration of the ſpherical figure of the ſpeculum, and ſo improper to procure that ſharpneſs and preciſion ſo neceſſary to a good reflecting teleſcope.

Suppoſing that the two foci of the different parts of the metal perfectly coincide, and that by the union of them, when the apertures are removed, the teleſcope ſhews the objects very ſharp and diſtinct, you are not however then to conclude that the inſtrument is not capable of farther improvement; for you will perceive a ſenſible difference in the ſharpneſs of the image, under diffrent poſitions of the great ſpeculum with reſpect to the little one, by turning round the great metal in its cell, and oppoſing different parts of it to different parts of the little metal, correcting by this means the error of one by the other. This attempt ſhould be perſevered in for ſome time, turning round the great ſpeculum about one-ſixteenth at a time, and carefully obſerving the moſt diſtinct ſituation each time the eye-piece is ſcrewed on: when, by trying and turning the great metal all round,

the

the diſtinct poſition is diſcovered, the upper part of the metal ſhould be marked with a black ſtroke, in order that it may always be lodged in the cell in the ſame poſition. This is the method Mr. Short always uſed; and the caution is of ſo much conſequence, that he thought it neceſſary to mention it very particularly in his printed directions for the uſe of the inſtrument.

And farther, Mr. Short frequently corrected the errors of the great by the little metal in another way. If the great ſpeculum did not anſwer quite well in the teleſcope, he cured that defect, ſometimes by trying the effect of ſeveral metals ſucceſſively, by this means correcting the errors of one by the other.

The apparatus above-deſcribed, for examining the parabolic figure of the ſpeculum, is repreſented in *Plate* V. *Optics*, *fig.* 7: A A is the mouth of the teleſcope, or edge of the great tube; B B is a thin piece of wood faſtened into and fluſh with the end of the tube, to which is permanently fixed the annular piece of paſteboard *c c*, intended to cover and to prevent the action of the correſponding part of the ſpeculum. D is another piece of paſteboard, fixed by a pin to the piece of wood B B, on which it turns as on a centre; ſo that the great annular opening H H may be ſhut up by the ring F F, or the aperture G G by the imperforate piece E, in ſuch manner that, in the firſt inſtance, the reflection may be from the centre, and in the latter, from the circumference of the great ſpeculum.

Mr. Mudge has remarked, that the operation of poliſhing will not proceed well in the heat of ſummer or the cold of winter; and that neither this, nor the other of grinding upon the the hones, will go on ſo well, unleſs they be continued uninterruptedly from beginning to end. In the above account it has been ſuppoſed, that the metal to be wrought was about four inches diameter; if it be either larger or ſmaller, the ſizes of the hones, bruiſer, and poliſher, muſt be proportionably different.

The proceſs for poliſhing the little ſpeculum of a teleſcope muſt be conducted in the manner already deſcribed, for that of the large one; only obſerving, that as the little metal has an uninterrupted face, without a hole, ſo there is no occaſion for one in the poliſher; and likewiſe that, as the ſpherical figure is the only object in this caſe to be attempted, the difficulty of execution is much leſs than in the former. As it is always neceſſary to ſolder to the back of the little ſpeculum a piece of braſs, as a fixture for the ſcrew to adjuſt its axis; Mr. Mudge has communicated a neat and ſafe method of doing it, which he received from the late Mr. Jackſon, and which may be very uſeful to the optical or mathematical inſtrument-maker upon other occaſions. Having cleaned the parts to be ſoldered very well, cut out a piece of tin-foil the exact ſize of them; then dip a feather into a pretty ſtrong ſolution of ſal ammoniac in water, and rub it over the ſurfaces to be ſoldered; after which place the tin-foil between them as faſt as you can (for the air will quickly corrode their ſurfaces ſo as to prevent the ſolder taking), and give the whole a gradual and ſufficient heat to melt the tin. If the joints to be ſoldered have been made very flat, they will not be thicker than a hair: though the ſurfaces be ever ſo extenſive, the ſoldering may be conducted in the ſame manner, only that care muſt be taken, by general preſſure, to keep them cloſe together. In this manner, for inſtance, a ſilver graduated plate may be ſoldered on to the braſs limb of a quadrant, ſo as not to be diſcernible by any thing but the different colour of the metals.

We ſhall cloſe this article with obſerving, that a method of giving the parabolic figure to his great ſpeculum was a point of perfection which Gregory and Newton had wiſhed for, but deſpaired of attaining, and which Hadley does not appear to have attempted either in his Newtonian or Gregorian teleſcope. Mr. Short is ſaid to have poſſeſſed the ſecret; however, it died with that ingenious artiſt. The method diſcovered by Mr. Mudge, above recited, is, as he has ſtrong reaſon to believe, the ſame with that of Mr. Short. See farther on this ſubject Smith's Optics, book iii. chap. ii. and Mr. Mudge's excellent paper in the Phil. Tranſ. vol. lxvii. part i. art. 16. p. 296—348. See TELESCOPE.

GRINDING is alſo uſed for a coarſer and leſs accurate method of ſmoothing or poliſhing the ſurface of a body, particularly glaſs for looking-glaſſes, &c.

In the new method of working large plates of glaſs for looking-glaſſes, coach-glaſſes, &c. by moulding, and, as it were, caſting them, ſomewhat after the manner of metals, deſcribed under the article GLASS, the ſurface being left uneven, it remains to be ground and poliſhed. In order to this, the plate of glaſs is laid horizontally on a ſtone in manner of a table, and to ſecure it the better, plaſtered down with mortar or ſtucco, that the effort of the workman, or of the machine uſed therein, may not ſhake or diſplace it; to ſuſtain it, there is a ſtrong wooden frame that ſurrounds it an inch or two higher than the glaſs: the bottom or baſe of the grinding engine is another rough glaſs about half the dimenſions of the former; on this is a wooden plank, cemented to it; and upon this are proper weights applied, to promote the triture, the plank or table being faſtened to a wheel, which gives it motion. This wheel, which is at leaſt five or ſix inches diameter, is made of a very hard but light wood, and is wrought by two workmen placed againſt each other, who puſh and pull it alternately; and ſometimes, when the work requires it, they turn it round. By ſuch means, a conſtant mutual attrition is produced between the two glaſſes, which is favoured by water and ſands of ſeveral kinds beſtowed between; ſand ſtill finer and finer being applied, as the grinding is more advanced; at laſt emery is uſed. We need not add, that as the upper or incumbent glaſs poliſhes and grows ſmoother, it muſt be ſhifted from time to time, and others put in its place.

It is to be noted, that only the largeſt ſize glaſſes are thus ground with a mill; for the middling and ſmaller ſorts are wrought by the hand; to which end there are four wooden handles at the four corners of the upper ſtone or carriage, for the workmen to take hold of, and give it motion. What remains to the perfection of glaſs, comes under the denomination of *poliſhing*, which ſee.

GRINE'TTA, in *Ornithology*, the name of a water fowl of the gallinula or moor-hen kind. See FULICA *Nevia*.

GRINNAN, in *Geography*, one of the ſmaller Hebrides, on the W. coaſt of Lewis. N. lat. 58° 1'. W. long. 7° 4'.

GRINSTED, EAST, a borough, market-town, and pariſh, in the hundred of Ruſhmonden, Suſſex, is built on a hill near the northern border of the county, where it joins Surrey. As a *borough*, Eaſt Grinſted has ſent burgeſſes to the national parliament even ſince the firſt year of king Edward II. A. D. 1307. Theſe are elected by 36 burgage-holders, 29 of whom are under the influence of the dukes of Dorſet. The county aſſizes for Suſſex are held in this town, though the county gaol is at Horſham. In the year 1616, Sackville, duke of Dorſet, built a college in this town, and endowed it for 24 aged perſons of both ſexes. It is governed by a warden and two gentlemen aſſiſtants. In the town is alſo a reſpectable charity ſchool. Eaſt Grinſted contains 381 houſes, and 2659 inhabitants. It is 28 miles S. E. of London, and ſeated on the great turnpike road between Croydon and Lewes. A market on Thurſday is chiefly for corn. Here are three annual fairs.

GRIP, in *Agriculture*, a ſmall trench, gutter, or ditch, which is cut acroſs a meadow, paſture, or ploughed field, for the purpoſe of draining it. In the laſt it is moſtly called a water or draining furrow.

It may frequently be a good mode in draining meadow lands in this way, to cut out the pieces in a ſomewhat wedge-like form, afterwards taking off the thin bottom parts, and then replacing them; by which means a hollow or opening will be left below for conducting off the water. See WATER-FURROW.

GRIP, in *Rural Economy*, a term ſometimes employed provincially to ſignify the hollow or cavity behind the cattle in cow-houſes or cattle ſheds, into which the dung and urine of the animals are diſcharged. Theſe cavities ſhould always be ſunk about eight, ten, or twelve inches below the ſurface on which the cattle ſtand, in order that they may be kept perfectly clean.

GRIPE, in *Mechanics*. See CRANE.

GRIPE, in *Rural Economy*, a name often provincially applied to ſignify a dung fork.

GRIPE *of a Ship*, in *Sea Language*, is the compaſs or ſharpneſs of her ſtem under water, chiefly towards the bottom of her ſtem.

The deſign of ſhaping her ſo is, to make her gripe the more, or keep a good wind; for which purpoſe, ſometimes a falſe ſtem is put on upon the true one.

GRIPE is alſo a ſea phraſe for a ſhip's being apt to run too much to windward of her courſe, particularly when ſhe ſails with the wind on her beam or quarter; this effect is partly occaſioned by the ſhock of the waves that ſtrike the ſhip perpetually on the weather-quarter, and force the ſtern to leeward; but principally by the arrangement of the ſails, which diſpoſes the ſhip continually to edge to windward, while in this ſituation of ſailing: in ſuch caſe they ſay ſhe *gripes*.

GRIPES, in *Rural Economy*, a name provincially applied to an implement of the forceps kind, which is employed for the purpoſe of eradicating and pulling up weeds of the thiſtle and other ſimilar ſtrong kinds, when growing among grain and other ſorts of crops. See WEEDING.

GRIPES, in *Medicine*, a pain in the lower bowels, of leſs ſeverity, and more moveable than the colic, occurring and ceaſing at intervals, and generally accompanied by a deſire to go to ſtool, and relieved by ſuch evacuation. The *gripes* are a common ſymptom of dyſentery; they are alſo occaſioned by the irritation of purgative medicines, or by any acrid matter paſſing through the bowels, as indigeſted food, an unuſual quantity of bile, &c. and ſometimes by flatulence only. In infants griping pains are very frequent, and ariſe principally from improper food, or from imperfect digeſtion, by which an acid is formed, which gives a green colour to the bile, and probably renders it more ſtimulating to the inteſtines; whence the gripes in children are commonly followed by green ſtools. The abſorbent earths, combined with rhubarb, and the ſlightly aromatic diſtilled waters, as thoſe of dill, fennel, or mint, ſpeedily relieve the complaint in children, in general. See INFANT; ſee alſo COLIC and DYSENTERY.

GRIPES, or *Colic*, in *Farriery*, is an acute diſeaſe, to which horſes are very often ſubject. There are three different ſpecies of this diſorder, *viz.* the flatulent or windy, the bilious or inflammatory, and the dry gripes. The firſt is occaſioned by drinking a large quantity of cold water when the body has been heated by exerciſe; or in horſes of delicate conſtitutions, and that have been accuſtomed to tender treatment by drinking very cold water, even without previous heating exerciſe. It is ſometimes produced by bad hay, oats, or clover, or ſuch as is new, and prone to fermentation. When this diſeaſe comes on without any apparent cauſe, Mr. White ſuggeſts that it may probably depend upon a ſpaſmodic action of the ſtomach or bowels, occaſioning a conſtriction of the inteſtine, and a confinement of air. The immediate cauſe of the formation and confinement of the air, however, is, as he conceives, weakneſs, or loſs of vital energy: and therefore the common flatulent colic is eaſily cured by grooms and farriers, who ſeldom give any other kind of medicines beſides thoſe of a ſtimulating quality. This diſeaſe is known by the horſe's alternately and ſuddenly lying down and riſing; by his ſtriking his belly with his fore feet, ſtamping with his fore feet, and refuſing his meat; and when the gripes are violent, by convulſive twitches, turning up his eyes, ſtretching out his limbs, and alternate ſweats and cold damps; ſtriving to ſtale, turning his head frequently to his flanks, rolling about, and often turning on his back. The confined wind has been ſometimes diſcharged by emptying the ſtraight gut with a ſmall hand dipt in oil, and thus the neck of the bladder is eaſed of its load, and the horſe ſtales. It is always proper to bleed young and plethoric horſes in the neck-vein. The following ball and clyſter ſeldom fail of giving relief: take Straſburgh or Venice turpentine, and pounded juniper berries, of each half an ounce; ſal prunella, or ſalt petre, an ounce; oil of juniper one dram; ſalt of tartar two drams; make theſe ingredients into a ball with any ſyrup; and give it whole, waſhing it down with a decoction of juniper-berries, or a horn or two of ale. If this ball does not ſucceed, and make the horſe break wind and ſtale plentifully, in an hour or two give him another ball, and add to it a dram of ſalt of amber; and this may be repeated a third time, if neceſſary: during the fit, let the horſe have gentle exerciſe. Let the following clyſter be given between the balls, or alone, and repeated occaſionally; take chamomile flowers two handfuls; aniſe, coriander, and fennel ſeeds, of each an ounce; long pepper half an ounce; boil them in three quarts of water to two; and add Daffy's elixir, or gin, half a pint: oil of amber, half an ounce, and oil of chamomile eight ounces The horſe ſhould be well rubbed, clothed, and littered with clean ſtraw up to his belly: and a pint of brandy, rum, or geneva, with as much ſweet oil, may be given for a drink; and if this ſhould not ſucceed, boil an ounce of pepper or ginger in a quart of milk, and add to it a handful of ſalt, and half a pint of oil, which, given warm, will purge in two or three hours.

In the firſt attacks of the colic, Mr. Taplin recommends the following ball to be given, according to the ſtate of the diſeaſe, every two, four, or ſix hours; *viz.* anniſeeds in powder, 1 oz.; mithridate, $\frac{1}{2}$ oz.; ginger and grains of paradiſe, of each in powder, 2 dr.; oil of anniſeed, and oil of juniper, of each, 1 dr.; with ſyrup ſufficient to form theſe ingredients into a ball. In caſes of flatulent colic, the following ball, adminiſtered every two, three, or four hours, according to the urgency of the ſymptoms, has been much recommended; *viz.* Venice turpentine, 6 dr., or 1 oz.; purified opium, from 1 dr. to $1\frac{1}{2}$ dr.; oil of anniſeeds, 1 dr.; and powdered ginger, 2 dr. At the ſame time clyſters, compoſed of the decoction of chamomile, or other common herbs, or of the gruel of oatmeal, with half a pint of olive oil, or an equal quantity of hog's lard, and half a pound of common ſalt, ſhould be occaſionally injected tolerably warm. Opium, it is ſaid, will ſometimes remove the ſpaſmodic affection that attends the flatulent colic, when other medicines have failed. Mr. White, in his "Compendium of the Veterinary Art," recommends to be given, as ſoon as the diſeaſe is obſerved, the following draughts, *viz.* 1. Balſam of

capivi, 1 oz.; oil of juniper, 2 dr.; ſpirit of nitrous ether, 1 oz.; ſimple mint water, 1 pint, to be mixed for one doſe. 2. Venice turpentine, 1 oz. mixed with the yolk of an egg; adding gradually peppermint water, 1 pint; ſpirit of nitrous ether, $\frac{1}{2}$ oz., for one doſe. 3. Camphor, 2 dr.; oil of turpentine, $\frac{1}{2}$ oz.; mint water, 1 pint, mixed for one doſe. A clyſter ſhould alſo be injected, compoſed of ſix quarts of water gruel or warm water, and eight ounces of common ſalt. If the diſeaſe has continued for ſeveral hours, and the pain appears to be great, with a quick pulſe, it will be adviſeable to bleed to three quarts, for preventing inflammation, and removing the ſpaſmodic contraction of the inteſtine. The draught and clyſter, recurred to on the firſt attack, will commonly be ſufficient; but if no relief be obtained in an hour or two, the draught ſhould be repeated, and the belly be rubbed for a conſiderable time with a muſtard embrocation. If the diſeaſe reſiſt theſe remedies, which will ſeldom happen, give a pint of caſtor oil with 1$\frac{1}{2}$ oz. of tincture of opium: when the horſe gets up, let him be rubbed perfectly dry by two perſons, one on each ſide, and let him afterwards be well clothed. The horſe afflicted with this complaint ſhould be provided with a large quantity of litter, that he may not injure himſelf during the violence of the paroxyſm. As this complaint is liable to occur on a journey, Mr. White recommends the following ball to be wrapped up cloſely in a piece of bladder, to be uſed as occaſion requires; *viz.* Caſtile ſoap, 3 dr.; camphor, 2 dr.; ginger, 1$\frac{1}{2}$ dr.; and Venice turpentine, 6 dr.; to be made into a ball for one doſe.

When ſtrong purgatives have been uſed in this complaint, ſuch as 12 or 14 drams of aloes, either alone or with calomel, which ſome farriers have injudiciouſly adminiſtered, and the bowels have been rendered ſo irritable by the violent effect of phyſic, that they become ſubject to troubleſome and even dangerous diſeaſes, and the horſe in this ſtate is attacked with colic or gripes, Mr. White cautions againſt the ſtrong remedies commonly employed, ſuch as ginger, pepper, &c., which often prove fatal by cauſing inflammation. In caſes of this kind the following draught will be found moſt uſeful; *viz.* oil of peppermint, 20 drops; tincture of opium, $\frac{1}{2}$ oz.; gum arabic (diſſolved in a pint of warm water), 2 oz., to be mixed for one doſe; the uſe of which ſhould be accompanied with frequent ſmall quantities of gruel, linſeed tea, or any other mucilaginous fluid, and the injection of a clyſter of the ſame kind.

The bilious inflammatory gripes are attended with a fever, beſides more of the preceding ſymptoms: the horſe alſo generally throws out a little looſe dung, with hot ſcalding water, the blackiſh or reddiſh colour and fœtid ſmell of which denote an approaching mortification. In this caſe three quarts of blood ſhould be immediately taken away, and the bleeding ſhould be repeated, unleſs the ſymptoms abate, in a few hours. The emollient clyſter, with two ounces of nitre diſſolved in it, ſhould be thrown up twice a day, and gum arabic water ſhould be plentifully drank, and a pint of the following mixture ſhould be given every two or three hours, till favourable looſe ſtools are procured, and then only night and morning, till the diſorder is removed. Take ſenna, three ounces, and ſalt of tartar half an ounce; infuſe them for an hour or two in a quart of boiling water, and add two ounces of lenitive electuary, and four of Glauber ſalts. If the diſorder increaſes, recourſe muſt be had to the Jeſuit's bark, which ſhould be given in the decoction to the quantity of a pint every three hours, with a gill of red port wine. In a caſe of leſs conſequence, take diapente, one ounce; diaſcordium, half an ounce; powdered myrrh, two drams; make theſe into a ball with two drams of oil of amber, and give it twice or thrice a day.

The dry gripes ariſe often from coſtiveneſs, and are diſcovered by the horſe's frequent and fruitleſs motion to dung, the blackneſs and hardneſs of the dung, the frequent and quick motion of his tail, the high colour of his urine, and his great reſtleſſneſs. The ſtraight gut ſhould, in this caſe, be ſearched by an oiled hand: then throw up the following emollient clyſter twice a day: take marſhmallows and chamomile flowers, of each a large handful; bruiſed bay-berries and fennel ſeeds, of each an ounce; boil them in a gallon of water to three quarts; and having poured the liquor into a pan, diſſolve it in half a pound of treacle, and a pint of linſeed, or of dry common oil. The purging drink preſcribed for the inflammatory gripes ſhould be alſo given till the ſymptoms are removed. The diet for a horſe with the gripes ſhould be ſcalded bran, warm water-gruel, or water prepared by diſſolving four ounces of gum arabic in a quart of water, and mixing it with other water.

Gripes, in *Sea Language*, is the name of a machine formed by an aſſemblage of ropes, hooks, and dead-eyes, and uſed to ſecure the boats upon the deck of a ſhip at ſea, and prevent them from being ſhaken by the labouring of the veſſel. The hooks, which are faſtened at their ends, are fixed in ring-bolts in the deck on each ſide of the boat; whence, paſſing over her middle and extremities, they are extended, by means of the dead-eyes, ſo as to render the boats firm and ſecure.

GRIPS, in *Agriculture*, a term applied to ſwarths, or ſmall heaps and handfuls of corn, lying in the fields after they have been cut down with the ſcythe or ſickle; but it is more commonly applied in the latter caſe.

GRIPSHOLM, in *Geography*, a town of Sweden, in the province of Sudermanland; 25 miles W of Stockholm.

GRISALBIN, in *Ornithology*. See Loxia *griſea*.

GRISARD. See Larus *Nævius*.

GRISAUNT, William, in *Biography*, an Engliſh phyſician of the 14th century, who ſtudied mathematics and aſtronomy with ſo much ſucceſs at Merton college, Oxford, that he was ſuſpected, like his countryman friar Bacon, of magic. From this cauſe, as it is ſuppoſed, he quitted his native country, and devoted himſelf to the ſtudy of medicine, firſt at Montpellier, and then at Marſeilles, where he fixed his reſidence, and lived by the practice of his profeſſion, in which he acquired much ſkill and eminence. The time of his death is unknown: but we are informed that he was living there, an old man, in 1350, and that his ſon, after being an abbot of canons regular at Marſeilles, at length arrived at the pontificate, under the name of Urban V. Griſaunt was the author of ſeveral works on mathematics, judicial aſtrology, and medicine. Hutchinſon's Biog. Med. Eloy. Dict.

GRISLEA, in *Botany*, in memory of Gabriel Griſley, a Portugueſe chemiſt and botaniſt, author of *Viridarium Luſitanicum*, publiſhed at Liſbon in 1661, and reprinted by Seguier, as well as by Ray. The latter ſpeaks of it as a rich catalogue, but faulty in not diſtinguiſhing the cultivated from the indigenous ſpecies, and evincing a deficiency of botanical learning in the author. Griſley, however, correſponded with the chief botaniſts of his day, eſpecially with Tournefort, to whom he ſent ſome new plants.—Linn. Gen. 189. Schreb. 252. Willd. Sp. Pl. v. 2. 320. Mart. Mill.

Mill. Dict. v. 2. Juss. 331.—Class and order, *Decandria Monogynia*, (*Octandria*; Linn.) Nat. Ord. *Calycanthemæ*, Linn. *Salicariæ*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, tubular, somewhat bell-shaped, with four, five, or six principal teeth, and as many external, minute, alternate ones, coloured, permanent, at length contracted just above the base, sometimes slightly curved upwards. *Cor.* Petals as many as the larger teeth of the calyx and inserted between them, opposite to the small ones, linear-lanceolate, acute, small, scarcely reaching beyond the calyx. *Stam.* Filaments eight, ten or twelve, awl-shaped, ascending, twice as long as the calyx, inserted into the lower part of its tube at the stricture; anthers roundish, versatile, incumbent, simple. *Pist.* Germen superior, ovate, with two furrows, nearly sessile; style thread-shaped, about as long as the stamens, ascending; stigma slightly notched. *Peric.* Capsule enclosed in the base of the calyx, ovate, with two lateral grooves, of two cells; its valves thin and brittle, at length irregularly torn. *Seeds* very numerous, minute, obovate or wedge-shaped, horizontal, closely crowded, covering the large, cylindrical, central, double column, which is united to the partition at each side.

Ess. Ch. Calyx with about five large and as many small teeth. Petals opposite to the latter. Stamens very long, ascending. Capsule invested with the permanent calyx, ovate, two-celled. Seeds numerous. Receptacle large, round.

Obs. The original species has a four-cleft, or often a five-cleft, flower, with eight or ten stamens; the others have a five or six-cleft flower, with ten or twelve; so that ten is the medium number.

1. G. *secunda*. Linn. Sp. Pl. 496. Lœfling. It. 245. —Leaves lanceolate, stalked, smooth. Branches horizontal. Flowers all turned upwards. Calyx half as broad as long.—Gathered by Lœfling in Terra Firma between Cumana and the river Orinoco, in February 1755. It does not appear that any of his specimens reached Europe. The only one we have ever seen was found near Curassow in the same neighbourhood, by J. Mærter, M.D. who returning to Europe in 1791, and being plundered of most of his effects amid the horrors of civil war in Flanders, liberally bestowed on the writer of this a parcel of most beautiful and rare South American plants, which were all he was able to save from ruin. This gentleman, sent out by the emperor, was the finder of the numerous plants in South America, which make so splendid an appearance in the works of Jacquin, though his name is scarcely, if at all, mentioned in books. He was subsequently professor of Botany at Friburgh in Suabia, and we hope still living.—By means of his specimen, and Lœfling's very exact description, we are enabled to give the following account of this rare plant, which is no where figured. The *stem* is shrubby, erect, twelve to eighteen feet high, with a few straight branches. The upper *branches* are scattered, parallel, long, spreading, slightly drooping, simple or subdivided, slender, smooth, leafy except in their lower part. *Leaves* opposite, stalked, two-ranked, spreading, lanceolate, pointed, entire, two or three inches long, smooth on both sides, with one rib, and numerous, nearly opposite, curved, simple veins; dark green above; much paler beneath, and besprinkled with numerous, small, scarcely discernible, glandular dots. *Footstalks* nearly half an inch long, smooth, channelled. *Stipulas* none. *Flower-stalks* axillary, opposite, rather longer than the footstalks, corymbose or cymose, all curved upward to one side, smooth, coloured, from six to ten-flowered. *Bracteas* few, at the base of the partial stalks, ovate, dotted. *Calyx* of a dark brownish crimson, bell-shaped, slightly angular, with usually four, but often five, principal divisions; its smaller ones, unnoticed by Lœfling, being very visible, like little prominent external teeth, before the others expand. The diameter of the calyx towards the top is full half its length, but the base is narrower, and as it advances in age, marked with a stricture. *Petals*, *stamens*, and *style* of an elegant scarlet. All these colours, with the green of the leaves, is lost in one nearly uniform dark brown in the dried plant, but the inside of the anthers remains of a vivid red or orange-colour. *Germen* only half ripe in our specimens, but evidently two-celled, with a transverse partition, joining the large, round, central column.

It is proper to observe that the words "*An Glaucis affinis?*" which finish the description of this plant in Lœfling's p. 246, belong to a widely different one, next described, which should have been numbered 105. This mistake of the editor, who was no other than the great Linnæus, is copied of course in the German edition, p. 318.

2. G. *punctata*. Buch. Cat. MSS. n. 34.—Leaves lanceolate, stalked, smooth. Branches and flowers erect. Calyx four times as long as broad.—Communicated from the East Indies by Dr. Francis Buchanan. The *branches* are opposite, round, smooth, and nearly erect. *Leaves* on short, thick footstalks, opposite, crossing each other in pairs, lanceolate, pointed, entire, two inches or more in length, smooth on both sides, pale and yellowish beneath and marked with much more evident dots than in the preceding. The lateral veins often unite in one common rib near the margin. *Flowers* red, in compound, nearly upright, corymbose, slightly downy clusters, about one-third the length of the leaves. *Calyx* much more slender than in the former, and nearly cylindrical, furrowed, minutely downy, often slightly curved according to the inclination of the stamens and style. The *flowers* are often six-cleft, with twelve stamens. Their buds are turbinate, with horizontally prominent, thick marginal points, which are the outer teeth of the calyx. This species is most allied to the following.

3. G. *tomentosa*. Roxb. Corom. v. 1. 29. t. 31. (Lythrum fruticosum; Linn. Sp. Pl. 641. Andr. Repos. t. 467.)—Leaves sessile, heart-shaped and clasping the stem at their base; downy beneath. Branches erect.—A native of hills and valleys in the northern provinces of Hindoostan, flowering during the cold and beginning of the hot season, according to Dr. Roxburgh, who sent seeds to the writer of this in 1793, which were raised in the botanic garden at Edinburgh. Others have since been raised about London, and the plant has been named *Woodfordia*, after a very liberal cultivator of exotics, but there is no question of its being a *Grislea*. It has the habit of the last, but the *leaves* differ in their insertion, and heart-shaped base, as well as in being downy beneath. The *flowers* are copious, in compound spreading clusters, scarlet and very handsome, often six-cleft. Their *calyx* is four times as long as broad, and usually a little curved, striated, scarcely downy.

The genus of *Lythrum* differs from *Grislea* in its large rounded petals, stamens scarcely exceeding the calyx in length, and capitate stigma. Its habit moreover is herbaceous. S.

GRISLEHAMN, or GRISLEHAVEN, in *Geography*, a sea-port town of Sweden, in the province of Upland; 37 miles E.N.E. of Upsal.

GRISON, in *Zoology*. See VIVERRA *Vittata*.

GRISONS, in *Geography*, a people in alliance with the Swiſs, forming three leagues, *viz.* the *Grey* league, the league of *God's houſe*, and the league of the *ten juriſdictions*, which ſee reſpectively. The reſpective communities of theſe three leagues have their peculiar conſtitutions, enjoy their municipal laws and cuſtoms, and are independent commonwealths in all concerns which do not interfere with the general policy of the whole republic, or the articles of the particular league of which they form a part. The country which they inhabit is bounded on the N. by the canton of Glarus, from which it is ſeparated by a chain of mountains, the higheſt point of which is the "Calendar," and the counties of Sargans and Pludentz, on the E. by the Tyroleſe, on the S. by the Bergamaſco, and the duchy of Milan, and on the W. by the Swiſs Italian bailiwicks, and the canton of Uri. This country conſtituted Upper Rhætia; and, at the decline of the Roman empire, fell under the dominion of the Oſtrogoths, who governed it by dukes. About the ſixth century it became ſubject to the Franks, and in the ninth was united to Germany. The ſeveral alliances or leagues were formed in order to repel the tyranny of the great barons. The league of *God's houſe* is repreſented by ſome writers as the moſt ancient (ſee GOD'S *houſe*); but according to others this league is ſuppoſed to have taken place between the year 1424, which was the era of the formation of the GREY *league* (which ſee), and 1436, the year in which the league of the *Ten* JURISDICTIONS (which ſee) became independent. The two former are ſaid to have eſtabliſhed an alliance in the year 1425 or 1427; and the firſt perpetual alliance was ratified by the deputies of the three leagues in the year 1471, or, as others ſay, in 1436. This confederation was renewed in the year 1544, and again in 1712. In conſequence of this union, the Griſons engage not to make any new alliance, nor declare war, nor make peace, but by common conſent. They alſo agree to favour one another, to guarantee one another's privileges, &c. Of all the conſtitutions in Switzerland, that of the Griſons is the moſt democratic, as their ſubordinates are totally independent of one another with regard to their particular police. The connection between the three leagues is maintained by means of an annual diet, of the congreſs, and of the three chiefs. The diet is compoſed of 63 deputies, and the three chiefs: the Grey league ſends 27, the houſe of God 22, and the Ten juriſdictions 14; theſe are choſen in the ſeveral communities by every male at a ſtated age. The diet aſſembles annually about the beginning of September at Ilants, Coire, and Davos, by rotation, and continues ſitting three weeks or a month. The chief of the league, in whoſe diſtrict the diet is held, is preſident for that term; the ſupreme authority is not abſolutely and finally veſted in the diet, but in the communities at large; for in all offices of importance, ſuch as declaring war, making peace, enacting laws, contracting alliances, and impoſing taxes, the deputies either have poſitive inſtructions from their conſtituents, or refer thoſe points, concerning which they have no inſtructions, to the deciſion of the reſpective communities, ſo that in effect the ſupreme power conſtitutionally reſides in the body of the people, and not in their repreſentatives at the diet. The three chiefs have no ſuffrage, when the communities ſend their inſtructions, becauſe they are not repreſentatives; but in all caſes which are either not referable, or afterwards ſubmitted to the communities, they vote in the ſame manner as the deputies. The deputies receive for their attendance a ſmall ſalary from the public treaſury, which never exceeds 5*s*. a day. The ariſtocratical party is ſtrengthened by the power delegated to the congreſs, which is an aſſembly formed by the three chiefs, and three deputies from each league. This congreſs generally meets in February or March at Coire; its office is to receive the votes of the ſeveral communities, relative to the queſtions referred to their deliberation at the laſt diet, and to communicate to each the reſult of the general deciſion. The three chiefs, as well as each of the other members of the congreſs, receive, towards defraying their expences, 54 florins, or about 4*l*. The three chiefs aſſemble regularly three times in the year at Coire; their principal meeting is in the month of May, when they write circular letters to the ſeveral communities, concerning the queſtions which are to be laid before the general diet. Throughout the three leagues the Roman law prevails, modified by municipal cuſtoms. The courts of juſtice in each community are compoſed of the chief magiſtrate, who preſides, and a certain number of jurymen choſen by the people. The priſoners are examined in private, and frequently tortured, for the purpoſe of forcing confeſſion, when the judges either divide the fines, or remit the puniſhment for a compoſition. Capital puniſhments are extremely rare, becauſe, it is ſaid, the judges receive greater advantage from fining than from executing an offender. The infliction of torture depends wholly upon the arbitrary will of the judges, a majority of whom may order it for an offence which by the ſtatutes is not capital, nor even puniſhable by corporal penalties. Even in the civil courts moſt cauſes are decided by bribing the judges, and appeals in thoſe communities, in which they are admitted, ſcarcely ſerve any other end than to enlarge the ſphere of corruption; but Coire and a few other places are excepted from this general reflection. Literature among the Griſons is at a very low ebb. The Proteſtants who receive a liberal education repair for the moſt part to Zuric or Baſle, and the Catholics to Milan, Pavia, or Vienna. Each community has a ſmall ſchool, in which the children are taught to read, write, and caſt accounts. At Coire there is a Latin ſeminary for the children of the burghers, and another, inſtituted in 1763, for the education of perſons intended for the church. There is alſo a typographical ſociety in this place for Latin, German, and Romanſh, and books in the Romanſh are printed in the Lower Engadina, and at Diſentis. The religion of the Griſons is divided into Catholic and Reformed, the only perſuaſions tolerated in this country. As the reformation was introduced into this country at an early period, about the year 1524, by the diſciples of Zuingle, the religion of the Proteſtant Griſons bears a greater reſemblance to that ſettled at Zuric, than to the church at Geneva; but the difference between the two ſects is very inconſiderable. The Proteſtants among the Griſons are more numerous than the Catholics, being eſtimated at about two-thirds of the inhabitants. In ſpiritual concerns the Catholics are for the moſt part under the juriſdiction of the biſhop of Coire; and for the reformed churches, each league is divided into a certain number of diſtricts, the miniſters of which aſſemble twice every year: theſe aſſemblies are called "Colloquia." Each colloquium

has

has its president, and each league a superintendent, called a dean. The supreme authority is vested in the synod, composed of the three deans, and the clergy of each league; and candidates for holy orders are examined before the synod, which assembles every year alternately in each of the three leagues. The number of reformed churches in the three leagues amounts to 135; 46 in the Grey league, 53 in that of God's house, and 36 in the league of Ten jurisdictions.

The salaries are small; the richest benefices yielding perhaps no more than 20*l.* or 25*l.* per annum, and the poorest scarcely 6*l.* The revenues of the three leagues arise from the following articles; *viz.* the duties upon the merchandise which passes through the Grisons, the Valteline, and Chiavenna, which are farmed at the rate of 17,000 florins, or about 1259*l.* 2. A third of the fines laid upon delinquents in the subject countries, of a fluctuating amount. 3. A tribute of 500 philips (a philip being equal to 5*s.*) from the Valteline, and 100 from Chiavenna. 4. A small fund, the principal part of which is only 4000*l.* vested in the English stocks. The population of the Grisons may be thus estimated: the Grey league contains 54,000 souls, the league of God's House 29,000, and the league of Ten jurisdictions 15,000: and if we add 87,000, the number of inhabitants in the Valteline, Chiavenna, and Bormio, the whole population of the Grisons and the subject countries, will amount to only 185,000 souls, or, allowance being made for deficiencies, will scarcely exceed 200,000.

The comerce of the Grisons is very contracted: the only exports (those of the subject provinces excepted) are cheese and cattle. They import grain, rice, salt, and silk stuffs from Milan; grain from Swabia and Tyrol; salt from Tyrol and Bavaria; fine cloth, chiefly English, French, and Silesian, through Germany; fine linens and muslins from Switzerland. As the only manufacture throughout the country is that of cotton established at Coire, the balance of trade must be against them; but they are enabled to support this deficiency by means of the estates which the Grisons possess in the subject provinces, by the sums which the governors draw from these provinces, by public and private pensions from France and Austria, by money saved in foreign services, and by the duties upon the merchandise passing through their territories.

The principal commerce of the Grisons and subject provinces is carried on with Milan across the lake of Como, by its branch the lake of Lecco, by the Adda, and by the canals of the Adda and Trezzo: Milan receiving from the Grisons only planks, stones for building, and coals.

The languages of the Grisons are the Italian, German, and Romansh. The Italian, which is a jargon similar to the Milanese dialect, is spoken by the inhabitants of Pregalia and Puschiavo, and in the vallies of Masox and Calanca. The German is spoken throughout the whole league of the Ten jurisdictions, a few villages excepted; in the league of God's house, at Avers, Coire, and the four villages; and in the Grey league, in various places. The Rhætian or Romansh is the vernacular tongue among the greater part of the Grisons. It is divided into two principal dialects, the one spoken in the Grey league, and the other in that of God's house. See ROMANSH.

The house of Austria, in modern times, has directed all the affairs of the Grisons with the most unbounded authority. However, as early as 1790, the agents of France were industrious in disseminating the new principles; but the great body of the people were averse from any innovation. At length, in 1794, a society of Grison Jacobins induced the people to abolish the ancient form of government, to substitute a national convention in the place of the general diet, and to throw themselves under the protection of France; and this revolution was accompanied with the usual horrors of pillage, banishment, and bloodshed. Bonaparte had no sooner concluded the armistice with the emperor, than he dismembered the Valteline, Chiavenna, and Bormio, and annexed them to the Cisalpine republic. This perfidious conduct roused the indignation of the Grisons, and served to favour the cause of the anti-revolutionary party, so that, in a subsequent stage of the French revolution, they rejected the mandate of the French directory to incorporate themselves with the Helvetic republic, and re-established the ancient government. However, on the renewal of hostilities between France and Austria, the country of the Grisons became the scene of bloody contests, and was alternately occupied by both armies, till at length it was constrained to submit to the power of France, and to form the sixteenth department or canton of Switzerland, according to the constitution of May 1800, empowered to send six representatives to the diet.

The country of the Grisons is mountainous, interspersed with vallies, which in some parts are impassable during a great portion of the year. The chief of these vallies lie towards the south, sunk in the Alps, which terminate at last in impassable glaciers, or elevated rocks, yielding no kind of vegetable. These glaciers are the sources of the principal rivers, as the Rhine, the Inn, and the Adda. The vallies afford some corn, but not sufficient for the supply of the inhabitants; the chief objects of attention to the farmers are their sheep and cattle, from which they obtain excellent butter and cheese. The mountains furnish good pasture, the hills supply chesnuts, and the vallies produce fruit. The mountains abound in metals, minerals, fossils, and mineral springs. The peasants wear linen and woollen cloth of their own manufacture.

GRISSEY, a town of the island of Java, and capital of a kingdom of the same name. S. lat. 7° 5'. E. long. 112° 48'.

GRIST denotes corn ground, or ready for grinding.

GRISTOW, in *Geography*, a small island in the circle of Upper Saxony, situated in the Direnow, between the town of Cammin and the island of Wollin, in Anterior Pomerania. N. lat. 53° 55'. E. long. 14° 40'.

GRITA, LA, a town of S. America, in the province of the Caraccas; 50 miles S.S.W. of Merida.

GRITHBRECHE, in our *Old Writers*, the same with breach of the peace. In this sense we find it mentioned in leg. Hen. I. cap. 36. "In causis regiis grithbreche 100 sol. emendabit."

It comes from the Saxon, *grithbryce*, which signifies the same.

GRITHSTOLE, a place of sanctuary. Blount. See FRIDSTOLE.

GRITS, in *Natural History*. See SABURRÆ.

GRIT-STONE, is a stone consisting of particles of sand agglutinated together. Of this kind of stone there are many varieties, differing in the size of the particles of sand that compose them, the different properties of these sands, and their different degrees of compactness and agglutination. Some of these stones are used for building, others for grinding, others for whetting sharp steel instruments, and others for filtrating water. See FILTRE, GRIND-*stone*, WHET-*stone*, and STONE.

GRIT-STONE, in *Mining*, signifies a hard granular or gritty stone, composed of grains of silex or quartz, cemented together, generally either by a silicious, or argillaceous or a ferruginous cement; the first of these, or the silicious grit-stones, are alone fit to be used in repairing roads, on account of

of the cements of the other ſorts being ſoftened by wet and the wear of carriage, the whole ſoon becoming a heavy ſandy mire upon the road, which, when the argillaceous parts are diſſolved and waſhed away by the winter rains, leaves theſe roads in the ſummer as intolerable from their depth of looſe ſand; as moſt travellers muſt have obſerved in the argillaceous grit-ſtone diſtrict about Aſhby de la Zouch, in Leiceſterſhire, and numerous other coal-countries, and the ferruginous grit-ſtone diſtrict about Woburn in Bedfordſhire, and other places. The greater part of the numerous grit-ſtone rocks and beds of ſuch ſtone in the coal-meaſures, are argillaceous, of a fine grit, with minute plates of mica, and are unfit for roads until hardened by the action of fire, being ſtill, however, very weak and improper road materials, if better could be procured.

A large portion of the argillaceous grit-ſtones have but a ſlight diſpoſition to periſh or moulder when expoſed, and can be uſed in walls and ordinary buildings; others will periſh in a few years, and a large portion of what appears, when firſt dug, at proper diſtances below the ſurface, to be very hard grit-ſtone, will, after a very ſhort time of expoſure, fall to a loamy or clayey ſand; ſuch very periſhable grit-ſtone ſtrata, are called by the colliers ſtone-binds, grey-beds, &c. except about Newcaſtle, where they are denominated ſand-ſtones.

In ſome places cryſtallized granular lime-ſtones occur, as in the yellow, or magneſian lime-ſtone range, near Mansfield, in Nottinghamſhire, and ſuch are ſometimes, though improperly, called grit-ſtones, or gritty lime-ſtones. See SAND-*ſtone*.

GRITZGALLEN, a town of the duchy of Courland; 20 miles S. S. W. of Seelburg.

GRIVE, JOHN DE LA, in *Biography*, was born at Sedan in the year 1689. He ſhewed a ſtrong inclination for the ſtudy of mathematics in early life, and was ſent to Paris, after a preliminary education in his native city. He entered into the congregation of the prieſts of St. Lazarus, in which he ſpent ſeveral years. Having taken orders, he was ſent by his ſuperiors to Poland, where, in 1713, he filled the poſt of profeſſor of theology in a houſe belonging to his order at Cracow. Still his mind was devoted to ſcientific purſuits, and being very expert in practical mathematics, he publiſhed "A Plan of Paris," which was ably and very accurately deſigned: but was ſpoiled in the engraving. He determined forthwith to be his own engraver, and publiſhed "The Environs of Paris;" "A Plan of Verſailles;" "The Gardens of Marly;" and "A Survey of the Royal Domains in the Vicinity of Paris;" all which are well executed, and held in high eſtimation by connoiſſeurs. He publiſhed "A Manual of Spherical Trigonometry," and was appointed geographer to the city of Paris. The laſt work which he undertook was the Topography of Paris on a large ſcale. But he died in 1757 before he had accompliſhed his deſign. Moreri.

GRIVELNIK, in *Geography*, a town of Walachin; 30 miles E. of Targoſyl.

GRIVENSKOI, a town of Ruſſia, in the province of Uſting; 96 miles E. of Lalſk.

GRIWHEE, a town of Africa, on the ſlave-coaſt. N. lat. 6° 30'. E. long. 1° 16.

GROAI, a town of Africa, on the ſlave-coaſt; 10 miles N. W. of Cape Palmas.

GROAIS *Iſle*, a ſmall iſland near the W. coaſt of Newfoundland. N. lat. 51°. W. long. 53° 50'.

GROAIX, a ſmall iſland, about four miles long and one and a half wide, near the W. coaſt of France and department of the Morbihan; 18 miles N. N. W. of Belleiſle; N. lat. 47° 39'. W. long. 3° 22'.

GROANING, in *Hunting*, a term uſed for the cry or noiſe of a buck.

GROAT, an Engliſh money of account, equal to four pence.

Other nations, as the Dutch, Polanders, Saxons, Bohemians, French, &c. have likewiſe their groats, groots, groches, gros, &c.

We had no ſilver money in the Saxon times bigger than a penny; nor after the conqueſt, till Edward III. who about the year 1351, coined groſſes, *i. e.* groats, or great pieces which went for 4*d.* a-piece; and half groats; and ſo the matter ſtood till the reign of Henry VIII. who, in 1505, firſt coined ſhillings.

GROATS, in *Rural Economy*, the ſmall grains formed from oats by being cut in the mill, after having the huſks or ſhells taken off from the grain.

GROBIN, or *Grobinen*, in *Geography*, a town of the duchy of Courland; 28 miles S. S. W. of Goldingen.

GROCERS, by the ſtat. 37 Edward II. cap. 5. a term uſed for thoſe who engroſs merchandize. See ENGROSSING.

But grocers are now thoſe who deal in ſugars, ſpices, &c. and form one of the incorporated companies of London. See COMPANY.

GRODEK, in *Geography*, a town of the duchy of Warſaw; 40 miles S. W. of Bielſk.

GRODNO, the principal, though not the capital, town of Lithuania, built upon an eminence, overlooking the river Niemen. This is a large ſtraggling place, but contains no more than 3000 Chriſtians, excluſive of the perſons employed in the manufacture, and about 1000 Jews. It has the appearance of a town in decay, containing a mixture of wretched hovels, falling houſes, and ancient palaces, with magnificent gateways, the remains of ancient ſplendour. A few habitations in good repair render the contraſt more ſtriking. The old palace, in which the kings reſided during the diets, ſtood upon a hill of ſand riſing abruptly from the river; but only ſome remains of the ancient walls exiſt. The new palace built, but not inhabited, by Auguſtus III. ſtands oppoſite to the former. It was enacted in 1673, that every third diet ſhould be held at Grodno; but this order has not been regularly obſerved. The late king of Poland eſtabliſhed a royal academy of phyſic in this town, in which ten ſtudents are inſtructed in phyſic and twenty in ſurgery, maintained and taught at the royal expence. The principal manufactures of this place are cloth and camlets, linen and cotton, ſilk ſtuffs, embroidery, ſilk ſtockings, hats, lace, fire-arms, needles, cards, bleaching-wax, and carriages. The country furniſhes ſufficient wood, flax, hemp, beavers'-hair, and wax, for the ſupply of the manufactories, that employ theſe commodities; but the ſilk, cotton, iron, colours, gold and ſilver for the embroidery, and fine thread from Bruſſels for the lace are imported. Theſe manufactories employ 3000 perſons; they were founded by the late king, and reflect conſiderable luſtre on the royal founder. The Roman Catholics have nine churches, thoſe of the Greek church have two; and the Jews here have a ſynagogue: 140 miles N. E. of Warſaw. N. lat. 53 34'. E. long. 24 12'.

GROEMS, a town of the duchy of Holſtein; ten miles S. of Ciſmar.

GROENLBERG, the largeſt of the projecting hills that run acroſs the valley of Drakenſtein, the ſoil of which is productive of fruit, wine, and corn. See DRAKENSTEIN.

GROENVELT, JOHN, in *Biography*, a phyſician, and member of the Royal College of London, in the ſeventeenth century, was born at Deventer, in the province of Overyſſel; he ſtudied and graduated at Utrecht, where he began the practice

practice of his profeſſion. But he likewiſe ſtudied under a celebrated lithotomiſt of Amſterdam, from whom he learnt that art, and whoſe eſteem he acquired by the dexterity with which he performed the operation, inſomuch that by his will this maſter bequeathed all his inſtruments to Groenvelt, with a requeſt that he ſhould employ them for the good of mankind. After this time he practiſed this art almoſt excluſively. He left three treatiſes; the 1ſt entiled "Diſſertatio lithologica variis obſervationibus et figuris illuſtrata." Lond. 1684.—2. "Practica qua humani morbi deſcribuntur." Francfort, 1688.—3. "Tractatus de tuto Cantharidum in Medicina uſu interno." Lond. 1698, &c. Theſe works were tranſlated into Engliſh, and the author's name was changed to *Greenfield*. Eloy. Dict. Hiſt.

GROGRAM, in the *Manufactory*, a ſort of ſtuff, made of ſilk and mohair, being in reality no more than a taffety, coarſer and thicker than ordinary.

GROHNDE, in *Geography*, a town of Weſtphalia, in the principality of Calenberg on the Weſer, where a toll is paid; nine miles S. of Hameln.

GROIN, in *Anatomy*. See INGUEN.

GROINE, in *Geography*. See CORUNNA.

GROINES, or GROYNES, in *Engineery*, are projections of wood from the outſides of a pier at the entrance of a harbour, to break the force of the waves and to retain the beach or gravel. See Smeaton's Reports, vol. i. pages 121, 271. Sometimes theſe are of piles and planks, ſometimes of faggot, or faſcinery ſtaked down, and ſometimes of hedging or thatching, that is made of ſtrong ſtakes and wattles of hedge-wood. Similar projections to theſe, from ſea-walls or banks, are called horſes, jetties, &c.

GROINS, in *Architecture*, a ſpecies of croſs paſſages arched above, ſo that the hollow of the one arch may cut through the ſolid into the hollow of the other arch, and leave a void at their mutual interſection.

It is evident, that the firſt conſtruction of groins muſt have been ſubſequent to that of ſimple vaulting, and that the idea muſt have originated in the formation of croſs-arched paſſages, particularly when it was neceſſary to occupy the whole or a part of the arches of both, or of the number which interſected at the ſame place. It is uncertain at what time they were firſt introduced into architecture: they are, however, of remote date; but their antiquity cannot be traced beyond the times of Roman power and grandeur. They became faſhionable at the decline of the empire, and are to be found in the elliptic paſſages of the Coliſeum, the temple of Peace, and the baths of Dioclefian at Rome. In the two latter buildings, the groins over the great halls ſpring from Corinthian and Compoſite columns, the moſt feeble of all ſupports, inſtead of the maſſive piers, which are only capable of reſiſting the lateral preſſure of the arches. Were it not for the auxiliary ſupport of the walls immediately behind in theſe buildings, the columns would not reſiſt the thruſt of the arches for a ſingle moment. The exterior walls of Dioclefian's palace at Spalatro in Dalmatia, and the Gymnaſium, at Alexandria-Troas in Ionia, are alſo vaulted with groins.

After the decline of the Roman empire, groins continued to be uſed in eccleſiaſtical buildings, and wherever grandeur or decoration was required, they were ſeldom or never omitted; they became the moſt conſpicuous features of all ſumptuous buildings and the pride of theſe times, and accordingly were decorated with ribs ſpringing from the walls, and branching over the groined ſurface of the ceiling interlaced with tracery: but except the pointed form of the arch, the principle of the groins remained the ſame for a conſiderable period of time, at leaſt ſo long as the ceiling remained plain. At laſt pillars decorated with columnar mouldings were attached to the walls inſtead of ſquare piers or the wall itſelf, in order to ſupport the ſpringers which were introduced under the groins; and theſe pillars being terminated with a capital, the abacus of which was of the ſame form, naturally ſuggeſted a ſmall change in the ſurface of the vaulting. For the columns now introduced preſented in the general appearance a ſaliant or external angle before the wall inſtead of a parallel ſide, and therefore the ceiling, to be conſiſtent with the baſe, naturally followed the general form of the abacus, ſo that the angles of the groined ſurface became more obtuſe, and the horizontal ſections of the groins at the ſpringing polygons; but the angles of theſe horizontal ſections at the diagonal ſpringers became more acute and the other angles more obtuſe till the ſides of the obtunding angles terminated in two interſecting ſtraight lines in the ſummits of the arches, and formed right angles, which were alſo the ultimate angles at the diagonal ſpringers. Hence the ſaid ſection of the groin above, any pillar being a ſemi-polygon, approached nearer to a ſemicircle as the number of ſpringers were greater, and this polygon ended in a rectangle in the ſummits of the croſs arches. It is not unlikely that this idea generated that of fan-work, and founded a ſyſtem of vaulting altogether upon a new principle, for the conſtruction of groins with diſſimilar ſections, ſpringing from a ſemicircular baſe, and ending in rectangles at the level of the ſummits, was imperfect.

It would eaſily occur, that any number of equal and ſimilar ribs, ſpringing at the ſame angle from a common centre in vertical planes, would ſupport themſelves, provided their upper ends were ſupported; and as the horizontal ſections of the ribs thus diſpoſed, would be in the ſemi-circumference of a circle, their common abutment at the top would be a ſemi-circle horizontally poſited. This idea would be complete by imagining ribs to riſe from four angles of a ſquare or oblong, in the ſame manner, but moſt perfect in the ſquare; then the four abutments for each ſet of angular ſpringers would be quadrants, and theſe quadrants would encloſe a ſpace, and form four convex boundaries to that ſpace, which, filled in with a flat vault, would key the whole together, and keep the quadrantal abutments ſtationary.

Having thus given a particular and tranſitive idea of groins, in order to illuſtrate this ſhort hiſtorical account, it will not be improper to define more particularly the various ſpecies of ſimple vaulting, and thence the general formation of groins, and to ſhew how to diſcriminate the various ſpecies, according to the ſeveral kinds of ſimple vaults which compoſe them; and laſtly, the geometrical conſtruction of groined centering and ribbing for plaſtering.

Definitions.—A ſimple vault is an interior concavity extended over two parallel oppoſite walls, or over all diametrically oppoſite ſides of one circular wall.

The concavity or interior ſurface of the vault is called the intrados.

The intrados of a ſimple vault is generally formed of the portion of the ſurface of a cylinder, cylindroid or ſphere, never greater than that of the half of the ſolid; and the ſpringing lines which terminate the walls which the vault riſes from, are generally ſtraight lines parallel to the axis of the cylinder or cylindroid.

When the vault is ſpherical, the circular wall terminates in a level plain at top, from which the vault ſprings, and forms either a complete hemiſphere, or a portion of the ſphere leſs than the hemiſphere.

Conic ſurfaces are ſeldom employed in vaulting; but when

when a conic ſurface is employed for the intrados of a vault it ſhould be ſemi-conic, with a horizontal axis, or the ſurface of the whole cone with its axis vertical.

All vaults, which have a horizontal ſtraight axis, are called ſtraight vaults.

All vaults, which have their axis horizontal, are called horizontal vaults.

A groin is that in which two geometrical ſolids may be tranſverſely applied one after the other, ſo that a portion of the ſurface of the groin will have been in contact with a portion of the ſurface of the firſt ſolid, and the remaining part in contact with the ſurface of the ſecond ſolid, when the firſt is removed.

The moſt uſual kind of groins is one cylinder piercing another, or a cylinder and cylindroid piercing each other, having their axis at right angles.

The axis of each ſimple vault forming the intrados of a groin, is the ſame with the axis of the geometrical ſolids, of which the intrados of the groin is compoſed.

When the breadths of the croſs paſſages or openings of a groined vault are equal, the groin is ſaid to be equilateral.

When the altitudes of the croſs vaults are equal, the groin is ſaid to be equi-altitudinal.

Groins have various names according to the ſurfaces of the geometrical bodies which form the ſimple vault.

A cylinder groin is that which is formed by the interſection of one portion of a cylinder with another.

A cylindroidic groin is that which is formed by the interſection of one portion of a cylindroid with another.

A ſpheric groin is that which is formed by the interſection of one portion of a ſphere with another.

A conic groin is that which is formed by the interſection of one portion of a cone with another.

The ſpecies of every groin, or ſingle arch, formed by the interſection of two vaults of unequal heights, is denoted by two preceding words; the former of which ending in *o* indicates the ſimple vault, which has the greater height, and the latter ending in *ic*, indicates the ſimple vault of the leſs height.

When a groin is formed by the interſection of two unequal cylindric vaults it is called a cylindro-cylindric groin, and each arch is called a cylindro-cylindric arch.

When a groin is formed by the interſection of a cylindric vault, with a ſpheric vault, the ſpheric portion being of greater height than the cylindric portion, the groin is called ſphero-cylindric groin.

When a groin is formed by the interſection of a cylindric vault with a ſpheric vault, and the ſpheric portion of leſs altitude than the cylindric portion, it is called a cylindro-ſpheric groin; and each arch is called a cylindro-ſpheric arch.

When one conic vault pierces another of greater altitude, the groin formed by the interſection is called a cono-conic groin, and each arch a cono-conic arch.

A rectangular groin is that which has the axis of the ſimple vaults in two vertical planes at right angles to each other.

A multangular groin is that which is formed by three or more ſimple vaults piercing each other, ſo that if the ſeveral ſolids which form each ſimple vault be reſpectively applied, only one at a time to ſucceeding portions of the groined ſurface, every portion of the groined ſurface will have formed ſucceſſive contact with certain correſponding portions of each of the ſolids.

An equiangular groin is that in which the ſeveral axes of the ſimple vaults form equal angles around the ſame point, in the ſame horizontal plane.

Cellars and other ſtrong places are frequently vaulted with groins of brick or ſtone, the outer ſupports are moſt commonly pilaſters, attached to a wall; the inner ones are ſquare, or rectangular, inſulated piers, from the corners of which, and from thoſe of the pilaſters ſpring the ſquandrals of the groin.

Illuſtration.—A, A, A, and *fig.* 1. No. 1. are the piers, upon which the groin is built.—No. 2. is the elevation of the nave, exhibiting one of its ribs, and the edges of the common and jack-ribs of the tranſept. In this groin the ſection, or generating figure, acroſs the nave, is a ſemi-ellipſis, and that acroſs the tranſept a ſemi-circle. It may eaſily be demonſtrated, that the line in which two vaults meet in a regular groin is all in one plane, the figure will therefore be the ſegment of a circle or ellipſis, cut off by a double ordinate, parallel to the tranſverſe or conjugate axis. For this purpoſe it is only neceſſary to ſhew that when two points are taken, one in each ordinate, which is at right angles to the axis of the vault, in the baſe of each generating figure, upon the ſame ſide of the axis, in ſuch a manner that the diſtance of the one point, from the neareſt extremity of the baſe, is to the diſtance of the other from its extremity, as the baſe of the former is to the baſe of the latter, the two perpendiculars, erected upon theſe points, are equal to one another.

Let the one generating figure be A K H D, *fig.* 2, No. 1; and the other E L H G, No. 2; and let the two baſes A D and E G, be biſected, each in C, and divided in the points B and F, ſo that A B : E F :: A C : E C, alſo let the two heights, C, H, be equal to each other, then will their parallels B K, and F L, be alſo equal to each other, for by a property of the ellipſis $AC^2 : AB \times BD :: CH^2 : BK^2 = \frac{AB \times BD \times CH^2}{AC^2}$ and by the ſame property $EC^2 : EF \times FG :: CH^2 : FL^2 = \frac{EF \times FG \times CH^2}{EC^2}$ but to ſhew the equality of BK^2, and FL^2, it is neceſſary to have the value of F L, in the ſame terms, with B K, for this purpoſe, we have A B : B D :: E F : F G = $\frac{BD \times EF}{AB}$ and A B : A C :: E F : E C = $\frac{AC \times EF}{AB}$ Therefore, by ſubſtituting $\frac{BD \times EF}{AB}$ for F G and $\frac{AC^2 \times EF^2}{AB^2}$ for EC^2 in the quantity $\frac{EF \times FG \times CH^2}{EC^2}$ it will then be $EF \times CH^2 \times \frac{BD \times EF}{AB} \times \frac{AB^2}{AC^2 \times EF^2}$ $= \frac{AB \times BD \times CH^2}{AC^2}$ = E L the ſame, value as found, for BK^2, therefore F L is equal to B K. Now it is evident, that if two ſections, B K H D, and E L H G, be moved along their axis, as has already been defined, until the lines K B and F L meet, the point K, will coincide with L, becauſe B muſt coincide with F, upon the diagonal line, conſequently the points K and L, will coincide in the common ſection, perpendicular to the baſe of the groin.—Now all other two points ſo circumſtanced, would likewiſe meet in a plane perpendicular to the baſe of the groin paſſing through the diagonal lines; therefore the common interſection of two cylindric ſurfaces, piercing each other, of the ſame vertical diameters (that is, the generating ſections, having their two parallel diameters equal to each other,) are in the ſame plane, and the common line is an ellipſis, whoſe centre is in the middle of the diagonal line. Now it has been ſhewn, that the nave is completely boarded in without having any reſpect to the tranſept.—In order to get the foot of the jack-ribs, it is found convenient to draw the two diagonals upon the nave, where the ſurfaces of the two vaults meet each other; this is nothing elſe than finding the covering of a cylindric ungula. Make a thin rule of a ſufficient breadth,

to fit the curved edge of the ſuperficies.—This rule is to be applied from the bottom or top of the interſection, and bent round upon the boards till the other extremity meet the top or bottom, and a line is to be drawn by the curved edge. The other three angles are to be drawn by the ſame rule, obſerving to reverſe the lines that are upon the ſame ſide to each other. To ſave time in fitting the boards of the tranſept, a mould is made for the ſuperficies of the ungula of this vault in the ſame manner. The boards for the covering are laid together upon a flat ſurface, to the breadth of the circumference of the vault, and a line is to be drawn by the edge of this mould acroſs the ends of the boards, obſerving to apply the mould at the proper angle from the bottom or top. A B D, N° 4, is half a rib of the nave; the circumference A D may be divided into the equal parts A, *t*, and lines drawn parallel to D B, cutting the diagonal A C, in the points *v*, and the baſe A B in *u*; I H or I G, N° 5, is made equal to the arc A D, by bending a thin ſlip of wood round the curve, and marking it at the points *t*, *t*, *t*: this ſlip of wood is to be ſtraightened, and the diviſion transferred to I G at *w*, *w*, *w*, &c. N 5; draw the perpendiculars *w*, *x*; make the lines *w*, *x*, equal to the lines *u*, *v*. A line being drawn through the points *x*, *x*, *x*, &c. will be the curve for the edge of the mould for finding the angular interſections upon the nave, with that of the covering of the tranſept. In like manner, the mould for cutting the ends of the boards will be found: A F E, N 4, is half the rib of the tranſept; divide the circumference into the equal parts A *z*, *z z*, *z z*; draw the lines *z y*, *z y*, parallel to E F, cutting the diagonal A C at the points *v*, *v*, *v*, and the baſe A E in the points *y*: put in ſmall tacks, or pins, at the points *z*, and bend a thin ſlip of wood round the arc; mark upon it the points *z* and the extremities of the arc; then ſtraighten it, and lay it upon any indefinite line.

From *o* to M, and *o* to L, N° 6, and mark the points *p*: draw the perpendiculars *p*, *q*; make the lines *p*, *q*, equal to *y v*; and through the points *q* draw a curve, and it will be the edge of the mould for cutting the boarding. In finding theſe moulds, it is not neceſſary that the diviſions round the arcs be equal; but it is convenient, as the arc may be divided into equal parts which form ſegments, whoſe chords differ in length, but an exceeding ſmall quantity from the arc itſelf. Theſe chords, repeated to the number of diviſions of the arc, upon a ſtraight line, will give the rectification of the curve nearly. When the rib of the nave is a ſemi-ellipſis, and that of the tranſept a ſemi-circle, it may be found very convenient to divide the circular arc firſt into equal parts; then drawing perpendicular lines to its baſe, to cut the diagonal from theſe interſections; draw lines perpendicular to the baſe of the other rib, to cut its curve, which will be divided into ſmall ſegments, whoſe curvatures are more proportional to each other, than thoſe of equal chords, as an elliptic arc upon the tranſverſe axis is much quicker towards each extreme than at the middle.

Groin Ribbing.

Timber Groins—Timber groins are thoſe which are conſtructed with timber, and plaiſtered, which form the concave ſurface of the groin, in the ſame manner as thoſe of brick or ſtone turned upon a centre.

There are two methods of forming and diſpoſing of the common ribs, the one, in which they are curved and placed at right angles to the axis of each of their reſpective vaults, and the other, in which they are all ſtraight, and placed parallel, excepting one placed between every two oppoſite piers, for the purpoſe of ſhortening the bearings of the ſtraight ribs. The former of theſe methods is ſhewn at A B C D, *fig.* 3, the latter at B E F C, and the conſtruction on the right-hand of the ſame figure. Suppoſe it were required to have the rib A G H of the tranſept a ſemi-circle, then that acroſs the nave I K L will, conſequently, be an ellipſis to the ſame height. The moſt expeditious method of finding the one from the other: take any number of points, in circumference H G A, and draw lines parallel to the axis, or ſides of the vault, cutting the diagonals from theſe interſections; draw lines parallel to the ſides, or axes, of the other vault. From the baſe J L make all the perpendiculars for the ellipſis I K L equal to thoſe of the ſemi-circle; from the interſections on either diagonal, draw perpendiculars to that diagonal, on either ſide of it; make theſe perpendiculars alſo equal to thoſe of the ſemi-circle.

In warehouſes, as the walls are frequently placed at remote diſtances, it becomes neceſſary to introduce many intermediate ſupports to the floors, which are frequently loaded with the greateſt weight; and as timber-floors are ſubject to both fire and rot, and thereby expoſed to ſudden danger, every means ſhould, therefore, be taken to render buildings of this deſcription proof againſt ſuch caſualties, at leaſt as far as appears eligible in the profits ariſing from the goods which are lodged in the building, being a full compenſation for the additional expences, nothing will contribute further to this end than groins, which, though not applicable to the upper ſtories of a building, (owing to the great expence which would be incurred by the extraordinary thickneſs of walling, and the diminution of ſpace which this would naturally occaſion,) may at all times be uſed in the cellars and ground ſtories, without much addition of labour, or expenditure of materials. It has been found, however, that brick groins, riſing from rectangular piers, are very inadequate to the weight they have to ſupport: we will, therefore, lay before our readers an ingenious tract by Mr. George Tappen, architect, where he clearly points out the diſadvantages of the preſent form, and ſhews how to remedy theſe evils by the introduction of a new manner of groining, which not only gives double the ſtrength, but occupies leſs ſpace, and is much more convenient for turning goods round the corners.

"On a new and more effectual method of building groined arches in brickwork, that they may better anſwer the various uſes they are intended for, in warehouſes of different deſcriptions, ſubterranean ſtructures, or undercroft, and other buildings; as is more particularly ſhewn by a model, made for practical demonſtration, which may be viewed at Mr. Narrien's, N 70, St. James Street.

It has long been experienced, and univerſally acknowledged, that the preſent eſtabliſhed method of erecting groined arches is a weak and imperfect conſtruction, and, conſequently, improper to be introduced into warehouſes, or ſuch other buildings as require a much greater degree of ſtrength and ſolidity than is uſual, in order to ſupport, with more ſafety, the immenſe weights and burthens which are conſtantly placed therein.

But, notwithſtanding this general opinion, I have never heard that any profeſſional man, or other qualified perſon, has hitherto given himſelf the leaſt trouble or concern in attempting to apply a remedy to the evil, by deviſing ſome more ſecure and judicious manner of conſtructing them, although it is unanimouſly confeſſed that ſuch an improvement would be attended with conſiderable commercial advantage.

Indeed, upon a ſlight inveſtigation of the ſubject, the objections raiſed againſt this kind of arches, as they are now built, appear to be too well founded to require much comment.

In the firſt place, it muſt be manifeſt to every obſerver who examines them, that a very material part of the ſubſtance of the bricks, forming the groined angle, is pared and cut away, with an intent of producing additional length to the

curve of that angle by which the joints of all the brick-work are preſerved on an exact level line, as well as from the unavoidable neceſſity of uniting and bonding the ſame into the face of the arch with which it is immediately connected.

Secondly.—The ſlanting, or oblique direction in which the bricks are cut and bedded at the angles of the groins (ſee W, *figure* 1, in the diagram hereto annexed), with an horizontal line at top, render them extremely liable to be thruſt out of their ſituations by any ſudden momentum, or extraordinary impulſe operating on the crown of the arch.

Thirdly.—Were the groins viewed in a ſectional repreſentation, they would preſent the pooreſt and moſt feeble of all forms thus applied, that of a wedge placed vertically on its blade; and at the ſame time diſcover ſo ſmall an area, and conſequently ſuch a want of ſolidity, as to appear incapable of ſuſtaining, ſo ſecurely as they ought, the combined lateral preſſure of the contiguous arches.

Laſtly.—The groins (being the parts where the greateſt reſiſtance ſhould be made), inſtead of ſpringing from a broad ſubſtantial baſe, have nothing elſe to reſt upon, than the moſt flimſy of all ſupports, namely, an extreme corner of a ſquare pier. Again, what may be urged, not only as a confirmation, but as an augmentation of the evils juſt mentioned, is, that when the crowns of theſe arches are loaded with ſtores and merchandiſe, the ſuperincumbent weight has been found, by experience, to act chiefly in the direction of the groins, although they are allowed to be the weakeſt parts of the arch; therefore it follows, as a natural concluſion, that the ſtronger theſe parts are made, the better the whole arch will be able to counteract the tendency of a fracture, and conſequently the greater burthen it will be capable of ſupporting, without the danger of giving way.

Thus having, I preſume, ſufficiently explained my objections to the old groined arches, I will now ſubmit a conciſe deſcription of my new method of building them, referring my readers to the conſideration of the model made for that purpoſe, which, though conſiſting of a ſingle arch only, will nevertheleſs impart a competent idea of a continuation of them where circumſtances may make it neceſſary.

Inſtead of the ſquare piers, ſo commonly uſed, I have adopted octangular ones, being better ſuited to the principles of the new method, as will readily be perceived by the inſpection of the model, or of the diagram hereto annexed: alſo, they occupy leſs ſpace on the ground than the ſquare piers, (being octagons inſcribed therein); nor are they ſo ſubject to injury at the angles, by the rolling of caſks or removal of goods, as thoſe which are ſquare.

The four-inch receſſes between the baſes of the ribs may, if thought beſt, be filled up to the height of the ſpringing courſe, and then the piers would be perfect octagons (as ſhewn by the pier O in the diagram); and conſequently all the angles, by becoming obtuſe, would be leſs expoſed to harm than they are even by this method; but the ſuperficial ſpace of two feet ſix inches in each pier would be loſt.

The octangular piers, meaſured acroſs each way from the feet of the ribs, are four feet eight inches, which is the ſize of the ſquare ones uſed in the tobacco warehouſes at the London docks, but the octagonal piers are attended with this ſuperior and apparent advantage: in each of them there will be a ſaving of room amounting to three feet nine inches, excluſive of the ſpaces between the ribs before mentioned, which ariſes from the truncation of the four triangles (marked *t*) produced by the inſcribing of an octagon within a ſquare. That is to ſay, each of the ſquare piers in the tobacco warehouſes of the London docks, though only the ſame ſize from out to out, occupy three feet nine inches more of the area, or ſuperficial content of the warehouſe, than the octagonal piers, excluſive of two feet ſix inches before mentioned, which added together, would make a ſaving of ſix feet three inches in every pier, if the ſmall ſpaces between the ribs were not filled up. This ſum, multiplied by the number of them throughout the whole building, would amount to a conſiderable loſs of room in regard to ſtowage. And here it ought to be particularly obſerved, that though the octangular piers contain leſs ſubſtance, by the cutting of the four angles than the others, they are nevertheleſs made conſiderably firmer; becauſe the croſs ribs of the contiguous arches, which reciprocally ſupport and reſiſt each other, have a broader footing on the main body of the pier, independently of the intervening ſpandrils, which are to be carried up to the level of the extrados of the arches.

The diſtance of theſe octangular piers from each other I have ſuppoſed to be twenty-one feet, which alſo tallies with the ſpace obſerved in the tobacco warehouſes at the London docks, and which has been proved by experience to be an advantageous diſtance between the piers, for the accommodation of various ſtowage in large warehouſes. I only allude to theſe works by way of a datum, (they being of national notoriety, and very juſtly of public approval,) ſince it is clear to every underſtanding, that the new method, as well as the old, may be practiſed with equal eaſe to any dimenſions, and with any kind of arch.

I have intended the diagonal ribs to conſiſt of two bricks and a half on the face, and two bricks in thickneſs; which alſo may be made larger or ſmaller, agreeable to the ſpan of the arch, the ſize of the piers, or the weight intended to be put upon them. The filling-in arches are meant to be one and a half brick in thickneſs, as is uſual, which may alſo be made thicker whenever it may be thought proper to increaſe the ſize of the ribs and piers. Now it is evident, by inſpecting the model, that theſe ribs, ſpringing not from a ſmall corner or edge of a ſquare pier, but from the ſides of a ſolid octagon, made ſtill more firm and immoveable by the counteracting agency of the oppoſite ribs, with flat ſpandrils above, muſt poſſeſs extraordinary ſtrength and durability. They abut againſt a ſtout ſquare key-ſtone, placed in the central interſection, or which may be brick-work inſtead; and, by their having to bear the whole of the weight placed upon the filling-in arches, they are to be worked throughout with ſolid unmutilated bricks, except ſuch cuttings as may be neceſſary for bond alone; and the whole being carried up at the ſame time, namely, the ribs R, filling-in arches F, and ſpandrils S, and well worked and bonded together in ſtrong flowing mortar, would, according to the ſubjoined mathematical calculation, be capable of ſupporting upwards of twice and a half the weight which the common groined arch of equal magnitude could ſuſtain.

As the diagonal of a ſquare is longer than one of its ſides, ſo it is equally obvious that the girth of the elliptic croſs-ribs muſt be greater than the girth of the ſemi-circular arch, on which account I found that it was not poſſible to keep the joints of the brick-work of the filling-in arches upon the ſame level as the joints of the brick-work compoſing the ribs, without cutting away and diminiſhing the real body and ſubſtance of the bricks, and thereby falling into one error by ſhunning another. But as it frequently happens, that which at the firſt appeared to be attended with conſiderable difficulty, ended in a novel expedient of connecting the ribs and the filling-in arches together in a much better and more ſubſtantial manner, than could poſſibly have been the caſe by any contrivance of making them coincide at the angles. That is, I was induced to ſet back the filling-in

arches four inches from the face of the ribs, which renders the cutting of groins totally unneceſſary, and thereby occaſions a ſaving of 3*l.* in point of labour to every arch, which, in an extenſive warehouſe, would amount to a large ſum of money; and it ought, at the ſame time to be recollected, that in many ſituations it is not eaſy to find a workman who perfectly underſtands the principle of cutting the groined angle; ſo that it muſt either be executed in a very imperfect manner, or elſe the work delayed, and perhaps with great inconvenience, until a more experienced bricklayer can be procured.

But what appears to be more deſirable than any pecuniary advantage is, that this method of ſetting back the filling-in arches affords to them a moſt excellent ſhoulder or abutment againſt the whole body of the ribs, as well as a better opportunity of bonding and connecting the ribs and filling-in arches together, in the interior part of the work, and occaſionally on the face, as will be more practically illuſtrated, by conſulting the ſeparate fragment (on a larger ſcale) appertaining to the model of the new improved method; by the inſpection of which, every perſon will be convinced, that all the bond and connection which can be either uſeful or neceſſary to the work, may be obtained with the greateſt eaſe, notwithſtanding the joints of the brick-work of the filling-in arches, and thoſe of the ribs are, not generally ſpeaking, upon the ſame level, though many of the courſes in the progreſs of the work will accidentally come ſo. Now, had the filling-in arches been brought forward ſo as to meet the angles of the ribs, there would inevitably have appeared a continued joint or line of ſeparation in the very worſt place of which it could have happened, *viz.* the angles of the ribs; becauſe, as before obſerved, the courſes of the brick-work cannot be preſerved altogether on the ſame level. Therefore, by ſetting back the filling-in arches, this practical deformity is not only avoided, but the arches themſelves, inſtead of thruſting againſt the extreme corner of the ribs, will, by this diſpoſition, exert their force againſt the whole ſubſtance of them, where there is evidently a greater power to reſiſt it.

All arches require a certain thickneſs for ſupporting their own weight, yet how to determine it is not eaſily done. Indeed the moſt able engineers and architects differ widely in the dimenſions they give, becauſe it is a ſubject which has never been reduced to mathematical inveſtigation, like the equilibrium of arches, but wholly depends upon practical experience, juſt as the thickneſs of walls in houſes and other buildings. But as the ſtrength of all arches, whether ſemi-circular, ſegmental, or elliptical, when of equal thickneſs at the crown, is in an inverſe proportion to their radii, as that of beams of equal and ſimilar ſections is to their lengths; and ſince it has been proved, by many practical inſtances, that an arch 14 inches thick is ſufficient for a radius of ten feet ſix inches, when ſtrengthened by horizontal ſpandrils above, and capable of bearing great weights, as is the caſe in the warehouſes at the London docks, the proportional thickneſs of an arch to any other radius of curvature at the crown will be readily found; or any other thickneſs, if neceſſary, may be aſſumed as a datum, to be employed in the above theorem, for the calculation of the thickneſs of arches of different radii. However, in the groined arch, which is the chief object of our enquiry, the groins alone have to ſuſtain, not only the weight immediately over them, but alſo that which is thrown upon the filling-in arches; they, therefore, demand as great a thickneſs as can conveniently be allotted them on a pier whoſe ſize is given: upon which account I have made the diagonal ribs of the new groined arch nineteen inches thick and twenty-three inches broad, which is as large a rib as could well be placed upon piers meaſuring only four feet eight inches from ſide to ſide, and thereby a great increaſe of ſtrength is gained over the old groined arch, where the groin is only fourteen inches ſquare, no thicker than the filling-in arches.

To conclude this diſſertation, it may not be improper to obſerve, that Dr. Hutton, in his Treatiſe on the Principles of Bridges, recommends the ſtones of the wall (or ſpandril,) over the extrados of the vouſſoirs of an arch to be bonded into the ſtones of the pier, and with one another; becauſe the pier will then carry part of their weight, and thereby oppoſe a greater power of reſiſtance to the thruſt of the arch: for the ſame reaſon, it would be equally adviſable in the new method of building groined arches, to carry up at the ſame time the diagonal ribs, filling-in arches, and ſpandrils, well bonding the whole together in one ſolid maſs.

Laſtly, the author feels confident, that if the prejudice of old cuſtoms be not permitted to overcome truth and uſeful improvement, the ſeveral ſuperior properties of his new method of erecting groined arches in brick-work, will be the means of bringing it into general practice in works of magnitude, to the utter excluſion of the old ſyſtem; ſince it has been proved, that the octagonal piers occupy leſs ſpace on the plan than the ſquare ones; alſo the new arch, by the introduction of the diagonal ribs, is two and a half times ſtronger than the old arch; and there will likewiſe be a conſiderable ſaving in point of labour, by the omiſſion of the groins; ſo that under the impreſſion of theſe united advantages he has extreme ſatisfaction in preſenting theſe explanatory remarks, with the practical model, to the conſideration of the public in general, and of the architect and builder in particular.

N. B. The difference of expence between the centering of the old and new method is ſo ſmall, that it has not been conſidered worthy of computation in the foregoing treatiſe.

Theory upon which the conſtruction of groined arches in brick-work is founded: with a compariſon of their ſtrength according to the preſent manner of building them, and the new method invented by Mr. George Tappen, architect.

Inveſtigated by John Narien.—In any ground arch, the diagonal ribs or groins being kept in equilibrio by the preſſure of the ſuperincumbent ſpandrils immediately over them, it is evident that if the weight of the filling-in arches which reſt upon the ribs with their proper ſpandrils and the loading above them, were in a conſtant ratio to the preſſure neceſſary for keeping the ribs in a ſtate of equilibration, then the whole groined arch would be in equilibrio in all its parts, and would therefore be the moſt perfect conſtruction for ſupporting the greateſt weight.

In the improved arch deſigned by Mr. Tappen, the filling-in arches evidently reſt upon, or are borne by the diagonal ribs; and in the old conſtruction they are ſupported in the ſame manner; becauſe in their mutual interſections, which produce the groined angle, a certain arch is included: but the principles of perfect equilibration cannot be adhered to in any practical work which requires an horizontal floor above, without a loſs of room below the arch. (See Dr. Hutton's Principles of Bridges, ſection ii. page 43, for an arch of equilibration.) Nor can the filling-in arches, with the loading over them, be made to throw upon every part of the ribs a weight proportional to that which is neceſſary to keep them in equilibrio: hence, in whatever way groined arches are conſtructed, there will always exiſt a certain defect in them, on both theſe accounts.

But, as groined arches are abſolutely neceſſary in warehouſes, and many other buildings, for the purpoſe of giv-

ing

ing communication throughout the ſame in every direction, which cannot be obtained where parallel walls are uſed; and as there is moreover a great ſaving of materials reſulting from the arches bearing on piers only, inſtead of ſuch continued parallel walls; it therefore follows, that every improvement which can be made in them muſt be a valuable acquiſition: eſpecially, as the firſt defect, of a want of equilibration in the ribs, exiſts in all arches built in the common way; and as the aberration from a true equilibrium, ariſing from the diſproportionate preſſure of the filling-in arches, is not ſo conſiderable but that its effects may, in a great degree, be counteracted by increaſing the ſtrength of the diagonal ribs.

From what has been juſt ſaid, it will clearly appear, that, as the filling-in arches are bonded with the groins independently of the ſpandrils above, the whole force of the ſuperincumbent weight will be found to exert itſelf againſt the ſubſtance of the groins alone; on which account they require the greateſt ſtrength that can be given them; at the ſame time, the filling-in arches ſhould be made to throw as little weight as poſſible upon them, particularly about the interſections of the ribs, that the tendency they have to fracture towards the crown may be diminiſhed as much as the nature of the caſe will admit. The advantages of the new groined arch over the old one, in theſe two points, will be the ſubject of the following inveſtigation; its ſuperiority in practice having been ſufficiently explained by the inventor himſelf in the preceding deſcription.

In the old arch, where the groins which have to ſupport the filling-in arches, ſpring from the extreme corners of the ſquare piers, the ſections of theſe groins form a ſquare (ſee *a*, *fig.* 2, in the annexed diagram), having one of its angles turned towards the centre of the curve, and its ſides equal to the thickneſs of the filling-in arches; whereas in the new arch, the ſection, taken in the ſame manner, forms a rectangle, equal in breadth to the ſide of an octagon inſcribed in the ſquare pier, and of a thickneſs which may exceed that of the old groin in any aſſigned proportion. Now the ſtrength of an arch, in its different points, is meaſured by the greateſt weight which it is able to carry on thoſe points without breaking; that is, in a ratio compounded of the reciprocal triplicate ratio of the ſine of the angle, formed by the curve or its tangent and the vertical line in its various points, and the reciprocal ſimple ratio of the radius of curvature in the ſame points. But, ſince the relative ſtrength of arches is to be determined by comparing them in their weakeſt parts (namely, the crown), the ſtrength of any arch at the crown, whether circular or elliptical, will be reciprocally as the radius of curvature at that point, ſince the angle formed by the tangent of the curve and vertical line at the point is a conſtant quantity, *viz.* a right angle in every arch; or reciprocally as the ſpan of the arches when the riſe of them is the ſame (as is the caſe of the diagonal ribs and groins of the new and old method), the thickneſs of the arches themſelves being alſo ſuppoſed the ſame. From this it will be evident, that the ſtrength of the ſame ribs, when of different thickneſſes, will be directly as the areas of their ſections and diſtances of the centres of gravity from the place where the fracture would end, and reciprocally as the ſpans of the arches: that is, if A repreſents the area of the ſection, G the diſtance of its centre of gravity, and S the ſpan of the arch; then the ſtrength of one arch to another will be as $\frac{A \cdot G}{S}$. Hence the ſtrength of the groins in the old arch, and the diagonal ribs in the new one, may be eaſily compared by taking the proportional meaſures of both.

Let the ſide of the ſquare pier be $= a$; then the thickneſs of the filling-in arches will be $= \frac{a}{4}$, which conſequently will be the ſide of the ſquare ſection of the groins in the old arch; its area, therefore, will be equal $\frac{a^2}{16} = A$, and its half diagonal $= \frac{1}{2}\sqrt{\frac{a^2}{8}} = G$, becauſe the diagonal of this ſquare groin is in the direction of the radius. The diſtance of the piers being $4.5\,a$, the ſpan of the diagonal groins will be $= \sqrt{2 \times (4.5\,a)^2} = 6.364\,a = S$; we have, therefore, $\frac{A \cdot G}{S} = \frac{\frac{a}{32}\sqrt{\frac{a^3}{8}}}{6.364}$ for the ſtrength of the old groin.

The ſide of the ſquare pier remaining ſtill $= a$ in the new arch, the breadth of the rib $= \sqrt{2\,a^2} - a$, which is the ſide of an octagon inſcribed within the pier. the thickneſs neceſſary for the rib will be $= \frac{a}{3}$: then the area of its ſection will be $= \frac{a^2\sqrt{2} - a^2}{3} = A$; $\frac{a}{6} = G$, and $5.364\,a + \sqrt{2\,a^2} = S$; conſequently $\frac{A \cdot G}{S} = \frac{a^2\sqrt{2} - a^2}{122.004}$, the ſtrength of the new rib.

If we aſſume $a = 4$ feet eight inches (the dimenſions aſſigned by Mr. Alexander to the piers of the ground arches at the London Dock tobacco warehouſes), the ſtrength of the old groins will be to that of the new ribs as 5.44 to 10.64, or as 1 to 1.96; which is nearly two to one in favour of the new conſtruction: and this will be the caſe whatever may be the extent of the arch, while the ſame proportions are preſerved throughout.

We have already obſerved, that the filling-in arches reſt upon the diagonal ribs, except ſuch ſmall parts as come directly on the ſides of the piers; and that any weight placed upon thoſe arches ultimately fall upon the ribs; it is, therefore, plain, that every half-rib ſupports the weight of two half filling-in arches, one on each ſide; and, conſequently, may be ſuppoſed to carry one whole arch. This, as we ſaid before, is productive of a certain evil, becauſe the weight incumbent on the filling-in arches affects the groins with a preſſure which has not a conſtant ratio to that which conſtitutes their equilibrium; we ſhall, however, preſently prove that this evil is not ſo great in the new arch as in the old one; becauſe the ribs in the former being broader than the diagonal of the ſquare formed by the ſection of the common ground-angle, the filling-in arches will contain ſmaller areas, and conſequently throw leſs weight on any given point of the ribs, eſpecially when the upper part is loaded with merchandiſe.

If the filling-in arches, with their horizontal ſpandrils, and the loading on the floor above, be cut by parallel vertical planes at equal diſtances from each other, into indefinitely narrow ſections, (as at S in the annexed *fig.* 2.) whoſe ends *c* and *d* bear upon the ribs, thoſe ſections will be to each other as their areas; but as the loading above is ſuppoſed to be equally diffuſed over the whole ſurface of the arch, the height, *k b*, will be always the ſame; in which caſe the weight upon the ribs, ariſing from the preſſure of the merchandiſe, will be nearly as the chord *c d*, which is known at any point of the rib or groin, it being equal to twice *g l*, the diſtance of the ſection of the filling-in arch from the interſection of the ſides of the diagonal ribs or groins, which form a right angle. For example, at two feet from V, the vertex or centre of the crown, which is at ten

inches

inches from *m*, the interſection of the ſuppoſed ſquare ribs in the groin of the old arch, the chord = twenty inches; while, in the new arch, where the ſame ſection of the filling-in arch is only diſtant 7.6 inches from *g*, the angle of interſection of the diagonal ribs, the chord is but 15.2 inches: hence, the weight incumbent on the ribs in the old arch will be to that in the new, at the ſame point, as 20 to 15.2; conſequently, the tendency the latter may have to break in its weakeſt parts, on this account alone, will be leſs than the former in the proportion of 1 to 1.3, nearly: and by compounding the two proportions juſt found, *viz.* 1 to 1.96, and 1 to 1.3, we have the comparative ſtrength of both arches in the weakeſt parts, namely, about the crown, as 1 to 2.55, or as 1 to $2\frac{1}{2}$ nearly. So that, if the old arch is capable of ſuſtaining 50 tons without danger, the new groined arch would, with the ſame eaſe, bear 125 tons, and in that proportion whatever might be the weight placed thereon.

It muſt be owned, that the ratio of the difference of weight of the ſections of the filling-in arches, in both methods, is variable in different parts, being greateſt in the parts adjacent to the interſection of the ribs or groins, and leſs the farther they are removed from it. Yet, as the parts near the vertex are thoſe where an exceſs of weight would be moſt productive of injury to the arch, it is evident that whatever tends, as the new ribs do, to leſſen the ſuperficies of the filling-in arches, and, conſequently, their weight, and the loading upon them at that place muſt be of the greateſt advantage.

The ſpan of the diagonal ribs being greater in the improved conſtruction than the groins of the old one, thoſe parts of the filling-in arches which lie over the ſmall triangles *s*, where the extreme corners of the ſquare piers would have come had they not been made octangular, are incumbent on the ribs in the former, which in the latter reſt immediately upon the piers themſelves: but this will be of no ſenſible diſadvantage, becauſe they fall ſo near the piers, while the greater length of the arch enables it to admit an horizontal line at top better than in the old conſtruction.

Several attempts have been made by engineers and architects to ſtrengthen the old groined arch, ſometimes by laying in the bricks circularly about the crown; but another method, which has been recently practiſed, is that of placing a certain number of the courſes of bricks from the vertex downwards, at right angles with the direction of the groins; as may be ſeen in the groining at the London Dock tobacco warehouſes But, for the information of builders in general, I will make a few obſervations on this laſt expedient, which, as well as the others, I do not conceive productive of any great utility; at beſt, it does not make the parts round the crown ſtronger than I have conſidered them in the above inveſtigation: for though the bricks, being ſo placed, oppoſe a reſiſtance to fracture more directly than when they ſtand ſo obliquely to each other as they do in the old way, yet, as it is not poſſible to continue them (where the ſquare pier is uſed) of the ſame form and dimenſions, down to the ſpringing of the groin, the effective ſtrength of the whole arch can, after all, be only equal to an uniform ſquare rib, ſuch as I have ſtated to belong to the old arch. Hence, the concluſions I have drawn, upon the comparative advantages of the old and new methods of building groined arches in brick-work, will not be in the leaſt altered: and I cannot help obſerving, that this laſt contrivance for ſtrengthening the angle of the old arch is a proof how much it has been thought neceſſary to increaſe the power and value of the groins, by endeavouring to make them broad, and give the bricks of which they are compoſed a direct bearing one againſt another; a benefit which, though it cannot be obtained by any partial application of thoſe principles, is certainly gained in a very complete manner by Mr. Tappen's new method; where the ribs are not only compoſed of bricks placed perpendicularly to the direction of the arch, but are alſo kept of an equal ſize from the octagonal baſe or pier on which they reſt, to the very ſummit of the arch, where they mutually join, by which means alone they can be ſaid to impart ſuperior ſtrength to the whole, and thereby render a groined arch built upon ſuch principles a valuable acquiſition in warehouſes, and other large buildings, where the greateſt weights are to be ſuſtained.

In a right ſphero-cylindric groin, *fig.* 2, are given the vertical ſection, paſſing through the centre of the ſphere, and the ſection of the cylindric vault, to determine the ſeat of the angle.

Let A B C D E F G H I K A be the plan whence the ſphero-vault riſes, and K L E the vertical ſection of the ſaid vault; M N O be the ſection of the cylindric part of the groin, and the line N K J be in the vertical plane paſſing through the axis of the cylinder, and centre of the ſphere. In the cylindric arc M N O, let there be taken any number of points *p*, *p*, *p*, &c. and draw the lines M R, *p q*, *p q*, &c. parallel to N S, cutting the ſpheric ſection K L E at the points R, *q*, *q*, &c.; deſcribe arcs *t u*, *t u*, &c. and through the points *u*, *u*, &c. draw a curve, and it will be the ſeat of the ſphero-cylindric curve on the ichnography. To find the ſeat or projection of the ſphero-cylindric curve on the ſection, let there be given the ſeat B *y y y* L inſtead of A *u u u* S. Draw M V parallel, and *p v*, *p v*, *p v*, N V perpendicular to N J, cutting M V at *v*, *v*, &c. Make W *x*, W *x*, W *x*, W X, equal to M *v*, M *v*, M *v*, M V. Draw W *z*, *x z*, *x z*, *x z*, X Z, perpendicular, and B *z*, *y z*, *y z*, *y z*, *y z* parallel to N J, and through the points *z*, *z*, *z*, *z*, *z*, draw a curve, which will be the ſeat of the ſphero-cylindric curve.

Given the ſections of the two arches of a cylindric groin to find the ſeats of the cylindric line.

Let A B C, *fig.* 3, be the arch, and D E F the other, and let A C and D F be their chords; produce C A to I, and F D to H, ſo as to cut each other at G. Draw B F perpendicular to A C, and E F perpendicular to D F, the former biſecting the chord A C at K, and the latter, D F at L. Draw B H parallel to C A, and E I parallel to F D; from the centre G deſcribe the quadrant H I. Take any number of points in the arc F B, and through theſe points draw lines parallel to B H: to cut H G from the cutting-points, deſcribe quadrants, which will cut G I: from the cutting-points in G I draw lines parallel to D F, cutting the arc D E. From the aſſumed points in the arc A B, and the cutting-points in the arc D E, draw lines perpendicular and parallel to A C, meeting each other, and through the meeting-points draw a curve, K F, and it will be the ſeat of the cylindric curve.

Given the ſeats A, B, C, D, *fig* 4, of the ſpringing points of the angular curves of a groin, ſuppoſing the axis of the one vault to be parallel to the horizon, and the other inclined to it, let B A repreſent the level line, and the angle B A D the inclination to the horizon; let the quadrangle A F H B A be an oblong, and A E F the ſection of the level vault, which let be a ſemi-circle, and ſuppoſe the angular curves to be in vertical planes. Draw the diagonals A H and F B, which will be the ſeats of the angular curves, cutting each other in G: draw B D perpendicular to A B. Aſſume any number of points in the arc A E, and draw lines parallel to A B, to cut A G and B G; from the cutting points draw lines parallel to B D, which produce beyond A D. From the points of interſection on A D, and on the parts produced, ſet off corre-

ſponding

ſponding ordinates of the quadrant A E, and draw a curve A C D through the extremity, and this will be the ſection of the other part. *Fig.* 5. is the boarding to cover the vaulted ſurface over A G F.

GROIN, in the *Pointed Style of Architecture*, a ſpecies of vaulting, in which the arches and ribs meet together in a common centre, as the limbs of the human body may, in a certain degree, be conſidered as meeting together in the natural groin.

GROLL, in *Geography*, a town of Holland, in the county of Zutphen, ſtrongly fortified, ſituated on the river Slinghe, whoſe waters fill the ditches around the fortifications; 19 miles E. of Zutphen. N. lat. 52° 5′. E. long. 6° 32′.

GROMA, among the *Romans*, a way-wiſer, or ſurveying inſtrument; whence thoſe who uſed it were called *gromatici*, and the place in the camp where it was kept, *groma*. Pitiſc.

GROMI, in *Geography*, a town of Ruſſia, in the government of Irkutſch; 112 miles N. of Balaganſkoi.

GROMING, a town of the duchy of Stiria; 25 miles W. of Rottenmann.

GROMMETS, in a *Ship*, are ſmall wreaths, formed of a ſtrand of rope, and uſed to faſten the upper edge of a ſtay-ſail to its reſpective ſtay, in different places. By means of the grommets the ſail is accordingly hoiſted or lowered. Inſtead of theſe, hanks have been lately introduced.

GROMPHENA, in *Botany*, Plin. lib. 26. cap. 7, a ſynonym of a plant, called alſo by Pliny *Symphonia*, which he ſays bears leaves alternately green and roſe-coloured, and which is therefore ſuppoſed to be the *Amaranthus tricolor* of Linnæus. By the tranſpoſition of a letter this name became *Gomphrena* in ſome old writers, in which form it was adopted by Linnæus for the *Amaranthoides* of Tournefort, *Caraveron* of Vaillant, our Globe Amaranthus. See GOMPHRENA.

GROMWELL, or GROMILL. See LITHOSPERMUM.

GRONA, from γρωνη, *a cavern*. Loureir. Cochinch. 459. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, four-cleft, permanent; its ſegments nearly equal; the upper one notched. *Cor.* papilionaceous. Standard inverſely heart-ſhaped, ſomewhat folded together; wings turbinate, obtuſe, ſhorter; keel inflexed, concave, its petals united on each ſide, in their lower part, to the wings, divaricated, and forming a hollow, beneath. *Stam.* Filaments ten, (ſimple and nine-cleft,) their ſheathing baſe aſcending; anthers roundiſh, minute. *Piſt.* Germen linear; ſtyle thread-ſhaped, equal to the ſtamens; ſtigma ſimple. *Peric.* Legume linear, ſtraight, compreſſed, pointed, hairy. *Seeds* numerous, compreſſed, minute.

Eſſ. Ch. Calyx four-cleft; upper ſegment notched. Keel of the corolla united to the wings at each ſide; gaping and hollow beneath. Legume linear, with many ſeeds.

1. G. *repens*. Dâu Lan rūng of the inhabitants of Cochinchina, where it grows on uncultivated riſing ground. The *ſtems* are numerous, ſomewhat ſhrubby, proſtrate, creeping. *Leaves* alternate, ſtalked, ovate, entire. *Stipulas* awl-ſhaped, in pairs. *Flowers* purple, in axillary and terminal, upright ſpikes. *Bractæas* pointed, two-flowered. *Loureiro.*

GRONAU, in *Geography*, a town of Weſtphalia, in the biſhopric of Hildeſheim; 9 miles S S.W. of Hildeſheim.—Alſo, a town in the biſhopric of Munſter; 25 miles N.W. of Munſter.

GRONDEUR, a name given by the French in America to a fiſh which is commonly eaten there; the jaws of which have been brought into Europe, and being examined by Mr. Juſſieu, were found beſet in a remarkable manner with teeth, which perfectly reſembled the bufonitæ, called *crapandines*, and by ſome *ſerpents-eyes*; and which, in their foſſile ſtate, had been for many ages accounted gems. The arrangement of theſe teeth is ſuch, that the whole flat ſurfaces of the upper and lower jaw are in a manner paved with them. They are of different ſhape and ſize in the different parts; thoſe placed towards the edges were of the ſmall and flat kind, commonly found in Malta, and called *ſerpents-eyes*; and the larger *toad-ſtones*, as they are called, were placed more towards the middle; the largeſt of all being placed in two ſtraight rows, or lines, along the centre of each jaw. Each of theſe teeth is articulated by a gomphoſis in the jaw, and when taken out, they all have that natural cavity which is found in the hinder part of the foſſile ones. The ſockets of theſe teeth have much the appearance of thoſe from whence teeth have been frequently changed, and probably the fiſh ſheds them often in the courſe of its life. Mem. Acad. Par. 1723.

GRONDINES, LES, in *Geography*, a town of Canada, on the river St. Laurence. N. lat. 46° 36′. W. long. 71° 58′.

GRONES, a cape on the N.W. coaſt of the iſland of Jerſey; ſix miles N.W. of St. Aubin.

GRONHAMN, a ſmall iſland in the gulf of Bothnia. N. lat. 62° 55′.

GRONINGEN, one of the ſtates of Holland, bounded on the N. by the German ocean, on the E. by Eaſt Frieſland and Germany, on the S. by Overyſſel, and on the W. by Frieſland. See HOLLAND.

GRONINGEN, the capital of the ſtate juſt-mentioned, is a large, rich, ſtrong, well-peopled, city; adorned with many excellent buildings, well fortified and guarded by ditches. The port is commodious, into which ſhips may enter by a canal, about nine miles from the ſea. It is interſected by the river Hunes, which paſſes through it to the ſea northward, and the Dunſter runs eaſtward from it to the river Ems. Some deduce its name from Grunnius, a commander of the Gauls; but others derive it from the excellent green paſtures which ſurround it. This city is governed by four burgomaſters, and a common council of twelve, who are ſovereign judges without appeal; beſides a chamber of juſtice, called "Oudermans," for the inhabitants of the country about Groningen, compoſed of the principal citizens. An univerſity was eſtabliſhed here in 1614, and endowed with the revenues of ſeveral monaſteries. This was anciently a free and imperial city; and it was likewiſe erected into a biſhopric. In 1795, it was taken by the French; 81 miles W. of Bremen. N. lat. 53° 11′. E. long. 6° 24′.

GRONNA, in our *Old Writers*, a deep pit, or bituminous place, where turfs are dug for burning.

GRONOVIA, in *Botany*, ſo named by Houſton, who engraved its parts of fructification in one of his unpubliſhed plates, ſubſequently given to the world by ſir Joſeph Banks, in honour of Dr. John Frederick Gronovius of Leyden. (See GRONOVIUS.) Rel. Houſt. 4. t. 7. This plate indeed is but a copy, like ſome of the others, the original having been loſt.—Linn. Gen. 111. Schreb. 154. Willd. Sp. Pl. v. 1. 1176. Mart. Mill. Dict. v. 2. Juſſ. 394. Lamarck. Illuſtr. t. 144.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Cucurbitaceæ*, Linn. Juſſ.

Gen. Ch. *Cal* Perianth of one leaf, ſuperior, bell-ſhaped, coloured, permanent, divided more than half way down into five lanceolate, equal, upright ſegments. *Cor.* Petals five, ſmall, ſpatulate, rather longer than the tube of the calyx,

calyx, and inſerted into its baſe. *Stam.* Filaments five, the length of the petals, inſerted alternately with them into the baſe of the calyx, awl-ſhaped, fringed, approximated with the petals into a tubular poſition; anthers erect, heart-ſhaped, two-lobed, projecting a little beyond the petals. *Piſt.* Germen inferior, turbinate, five-cornered; ſtyle cylindrical, the length of the filaments; ſtigma capitate, undivided. *Peric.* Berry dry, roundiſh, five-cornered, coloured, crowned with the calyx, of one cell. *Seed* ſolitary, roundiſh, large.

Eſſ. Ch. Petals five, inſerted, between the ſtamens, into the baſe of the bell-ſhaped calyx. Berry dry, five-cornered, inferior, with one ſeed.

1. G. *ſcandens*. Linn. Sp. Pl. 292. Mant. 343. Jacq. Coll. v. 3. 197. Ic. Rar. t. 338. (G. ſcandens lappacea, pampineâ fronde; Mart. Cent. 40. t. 40.)—Gathered by Houſton, near Vera Cruz. *Root* annual. Whole *plant* fœtid, rough with minute hooked and ſtinging briſtles, by which it adheres to every thing within its reach, and ſupports its weak, and long-branched, but not twiſting nor properly, climbing *ſtem*. *Leaves* alternate, ſtalked, heart-ſhaped, three-lobed, coarſely ſerrated, acute, flat. *Flowers* in ſtalked, three-cleft cymes, oppoſite to the leaves, inodorous. *Calyx* pale yellow. *Petals* orange. *Anthers* brown.

We have derived much additional knowledge of this plant from Jacquin, who cultivated it in his ſtove, where he ſays it flowered from June to October. It has nothing but rarity to recommend it, and is therefore merely mentioned in the Hortus Kewenſis becauſe the ſeeds were ſent into this country by Houſton in 1731, and raiſed at Chelſea, but it does not appear that the plant ever flowered, and being annual, not perennial, was probably ſoon loſt. There can be no doubt reſpecting the natural order to which this genus belongs, notwithſtanding its imperfect reſemblance to *Loaſa*, and the heſitation of Juſſieu; for the notch in the ſtigma is more viſible in the copy of Houſton's figure than in the original, nor does it exiſt in nature.

GRONOVIUS, JOHN FREDERIC, in *Biography*, was born at Hamburgh in 1611. He received a learned education, and afterwards travelled over the greater part of the continent for improvement. His extenſive learning cauſed him to be invited to occupy the profeſſorſhip of Greek and Belles Lettres at Leyden, vacant by the death of Daniel Heinſius. He died in that city in 1672. He was author of "A Diſſertation on the Sylvæ of Statius," and of three books of "Obſervations," containing corrections and explanations of many paſſages of the ancients. In 1656 he publiſhed "A Treatiſe on the Seſterce," which was afterwards reprinted at Leyden with the title "De Vetere Pecunia." Of the Claſſics, he edited Plautus, Salluſt, Livy, Seneca, Pliny, Quintilian, and Aulus Gellius. Moreri.

GRONOVIUS, JAMES, ſon of the preceding, was born at Deventer in 1645, and, at an early period, was initiated into the ſtudy of the claſſics: in this department of knowledge, as alſo in the ſtudy of the law, he made a very rapid progreſs. In 1688 he came to England, where he contracted an intimacy with the moſt learned men in the two univerſities, and in the metropolis. He afterwards went into France and Flanders, and in 1672 he accompanied the ambaſſador from the States-General to Spain, and returning by way of Italy, he was received with diſtinction by Coſmo, grand duke of Tuſcany, who gave him the profeſſorſhip at Piſa. Soon after his return to Deventer he was appointed profeſſor of Greek and hiſtory in the univerſity of Leyden, and in 1701 he was nominated geographer to the univerſity. He died in 1716, leaving behind him a great character for learning; but he was apt to treat thoſe who differed from him, however wiſe and eminent for literature, with contempt. As the editor of many of our moſt eſteemed claſſics his reputation is ſtill very great. He corrected and wrote annotations on Macrobius, Polybius, Tacitus, Seneca, Pomp. Mela, Aul. Gellius, Cicero, Ammianus Marcellinus, Q. Curtius, Suetonius, Phædrus, Arrian, Minut. Felix, Herodotus, &c: he wrote notes upon ſome other authors, and diſſertations on various ſubjects of antiquity. He publiſhed a "Theſaurus Antiquitatum Græcorum," in thirteen volumes folio, and a Latin verſion of "Agoſtini on Ancient Gems."

GRONOVIUS, JOHN FREDERICK, a phyſician and botaniſt of conſiderable learning, was born, we preſume in Holland, in 1690. He took his doctor's degree at Leyden in 1715, on which occaſion he publiſhed a diſſertation upon *Camphor*, of the natural hiſtory and preparation of which, he gives much new information, properly diſtinguiſhing between the camphor of Japan, and of Borneo, a ſubject concerning which little was known before his time, and which is ſtill far from being exhauſted. (See CAMPHOR.) He ſettled at Leyden, and became one of the chief magiſtrates. He adopted the prevailing taſte of his countrymen for making collections of natural hiſtory, and in 1740 publiſhed his *Index Suppellectilis Lapideæ*, or a ſcientific catalogue of his own collection of minerals, drawn up under the inſpection, and with the aſſiſtance of, Linnæus, as in a great meaſure appears from the dedication of the 2d edition to that eminent man in 1750, as well as from the latter having included this pamphlet in the choſen, and uniformly bound, collection of his own works for his library. In a letter to Haller, in 1737, he mentions Gronovius, with Burmann and Adrian Van Royen, as principally anxious to increaſe their collections of dried plants, inſtead of ſtudying genera; for indeed that ſtudy was juſt then more neglected every where than it had for ſome time been, and Linnæus was deſtined to revive it. Gronovius received from Clayton various ſpecimens of Virginian plants, which he, with the aſſiſtance of Linnæus, then reſident in Holland, arranged according to the ſexual ſyſtem, and with proper ſpecific characters, deſcriptions, and ſynonyms, publiſhed under the title of *Flora Virginica*, in 1739, in 8vo. A ſecond part or ſupplement of the ſame work appeared in 1743, and a third was preparing when he died. This laſt being afterwards incorporated with the two former, the whole was publiſhed in quarto by his ſon in 1762.

In 1755 came out his *Flora Orientalis*, in 8vo., the materials of which were afforded by the very magnificent herbarium of Rauwolf, collected in his travels in the Eaſt during the years 1573, 1574, and 1575, and which, by favour of queen Chriſtina of Sweden, came afterwards into the hands of the learned Vossius, who allowed the chief Britiſh botaniſts of his day to ſtudy and quote it, and after whoſe death it was purchaſed for the public library at Leyden, where, if not recently removed, it ſtill remains. This collection is one of the beſt preſerved, and more remarkable for the ſize and perfection of its ſpecimens, than any we have ever ſeen. Gronovius determined by it above 330 ſpecies of oriental plants, no doubt an inconſiderable part of the botanical riches of ſo various and fertile a ſoil, but a valuable addition to the knowledge of that day. The work is arranged after the Linnæan method, but trivial names, though invented and publiſhed in the firſt edition of the *Species Plantarum* two years before, are not adopted, nor does the author appear to have uſed this publication. He was however in frequent correſpondence with Linnæus, whom he furniſhed with numerous ſpecimens of American plants ſent by Clayton, and with whom he conferred on the ſubject

ſubject of fiſhes amongſt others. Haller mentions him as having written learned notes to the 20th and following books of Pliny. He continued to enrich his muſeum, and to devote it to the uſe of all who were deſirous of conſulting it, as long as he lived. In the year 1750 Gronovius is repreſented as labouring under the gout, as well as a hernia, but he lived to the age of 72, dying in 1762. His herbarium was, after the death of his ſon, purchaſed by ſir Joſeph Banks. Hall. Bibl. Bot. and Epiſt.—Gronovii opera.

Gronovius, Laurence Theodore, ſon of the preceding, was born at Leyden in 1730. He took the degree of doctor of laws, and, like his father, attained to the chief civil honours of his native place. From him he imbibed a taſte for natural hiſtory, and, as we have already mentioned, edited the lateſt and completeſt edition of the *Flora Virginica*. He particularly excelled in the knowledge of fiſhes; but moſt departments of ſyſtematic zoology engaged his attention.

He publiſhed in 1754 his *Muſeum Ichthyologicum*, a handſome folio, with ample deſcriptions of the ſpecies. The ſecond part appeared in 1756, accompanied by deſcriptions of the ſerpents in his father's muſeum.

In 1763 appeared the *Zoophylacii Gronoviani faſciculus primus*, containing deſcriptions of a few quadrupeds, more *amphibia*, and a ſtill greater number of fiſhes, all from the ſame muſeum; the latter illuſtrated by 13 good plates, exhibiting 38 ſpecies. The ſecond faſciculus of the ſame work, publiſhed in 1764, deſcribes the inſects of his collection, of which numerous ſpecies are engraved on four copper plates. A third and laſt, with three plates, came out in 1781, after the death of the author, which happened in 1777.

He publiſhed in 1760 a very valuable work in quarto, entitled *Bibliotheca Regni Animalis atque Lapidei*, on the plan of the *Bibliothecæ Botanicæ* of Linnæus and Seguier, with an excellent *Index Rerum*, highly uſeful in ſuch a publication. He furniſhed moreover an appendix of 65 quarto pages to the ſaid work of Seguier.

GROOM, denotes a ſervant in ſome inferior poſt: in which ſenſe it amounts to the ſame with the old word, *garcio*, and the French *garçon*.

The word is formed from the Flemiſh, *grom*, *puer*, a boy.

Groom is the denomination of ſeveral officers and ſervants in the king's houſehold.

There are grooms of the almonry, grooms of the compting houſe, grooms of the great-chamber, the privy-chamber, and the bed-chamber, grooms of the robes, of the ward-robe, &c.

Groom *of the Stole*. See Stole.

Groom *Porter* is an officer of the houſehold, whoſe buſineſs is to ſee the king's lodging furniſhed with tables, chairs, ſtools, and firing; as alſo to provide cards, dice, &c. and to decide diſputes ariſing at cards, dice, bowling, &c.

Groom is more particularly uſed for a ſervant, appointed to attend on horſes in the ſtables. See Equery.

GROOVE, in *Architecture*, a channel cut in a piece of wood, by taking away a rectangular priſm adjacent to any of its ſuperficies, and thereby forming two internal angles and two external angles on the ſaid piece; and hence a groove differs from a rebate in this, that the ſame ſolid is taken away in both; the part taken away in the former always leaves the ſurface equally prominent on both ſides of the groove, whereas in the latter it is only ſo on one ſide, the arris being cut away, and has only one internal angle. Grooves are ſometimes uſed by way of ornament and ſometimes to inſert the tongue of ſome other piece of work, and by this means faſten the part which contains the groove to the other which contains the tongue.

Groove alſo denotes a gardener's tool for tranſplanting flowers.

Groove, or *Groof*, in *Mining*, ſignifies a mine or ſhaft, ſometimes alſo called a delf.

Groove-*cloaths*, are a dreſs of very coarſe flannel, which the miners wear when at work: often their whole dreſs conſiſts of a pair of ſuch trowſers and ſhoes; a practice which cannot be too much condemned in mines ſubject to fire-damp exploſions; ſince the univerſal though ſlight burning which naked men receive on ſuch occaſions often proves fatal, when if properly, or rather extra cloathed, on ſuch occaſions, they would ſcarcely have ſuffered any inconvenience, as juſtly obſerved by Mr. John L. Radley, in an excellent paper on the ſubject of Damps, written ſince that article in our work was publiſhed. See the Philoſophical Magazine, vol. 35, p. 1.

Groove-*fellows*, in *Mining*, ſignify the partners or fellow-workmen in a mine.

Groove-*ſpade* is a ſhort-handled ſpade uſed by miners and the dreſſers of ore.

GROOVERS, ſignify the miners or workmen in a mine.

GROOZDISHYS, in *Botany*, a name given by the Ruſſians to a ſpecies of muſhroom reſembling our pepper, or milky-muſhroom, deſcribed by Liſter, Ray, &c. but larger. The groozdiſhys is very broad and thick, and abounding with an acrid juice. The Ruſſians preſerve them in pickle, and eat them with their meats. When eaten freſh they inflame the mouth and throat, and endanger ſuffocation. Phil. Tranſ. N° 89.

GROPZIC, in *Geography*, a town of Germany, in the principality of Anhalt-Deſſau, on the Fuhne; 12 miles S. W. of Deſſau. N. lat. 51° 45'. E. long. 12° 1'.

GROS, Peter le, in *Biography*, an eminent ſculptor, was born at Paris in 1666. He was inſtructed by his father in the art of deſign, and at an early age he had made ſo much proficiency that he was nominated, among other young perſons, to be ſent to Rome, at the king's expence, to ſtudy the fine arts. He quickly obtained a high reputation, and had a ſhare in ſome conſiderable pieces of ſculpture that were carrying on. He remained at Rome a few years, and returned to France, where, during a reſidence of two years, he executed ſome works at Paris and Montmorenci, but the jealouſy of the artiſts rendered his life uncomfortable, which haſtened his return to Rome. He ſtood very high in his profeſſion, but was ſubject to the ſtone, for which, in the midſt of his labours, he underwent the uſual operation. He died in 1719, at the age of fifty-three. His works are chiefly found in the churches of Rome, and ſome of them are much admired. At the Tuilleries is a ſtatue of a Roman lady in a Grecian dreſs, of antique ſimplicity, which he copied, with ſome improvements, from an original at Florence.

Gros, Joseph le, a French ſinger with a very powerful, natural counter-tenor voice. We know not what effect the performing of the principal part in the operas of Gluck, Piccini, and Sacchini, may have had on this ſinger's ſtyle of ſinging; but in the year 1770, when we heard him at Paris, in the *Concert Spirituel*, ſinging a ſolo verſe in a motet, it was ſo much *à gorge deployer*, that he ſeemed crying out for help againſt aſſaſſins or wild beaſts, with which the audience, however, were extremely delighted. In the opera of Zaide, compoſed by Royer in 1739, who was formed entirely on the ſchool of Lulli, M. le Gros performed the principal man's part, in the national ſtyle of ſinging, of ſtill a higher period; yet ſo much improved was this ſinger in 1780, or

his biographer, M. Laborde, was ſo partial to his talents, that we find the following ſplendid eloge in the third volume of Eſſais ſur la Muſique, p. 511.

"Joſeph le Gros, an excellent muſician, a good compoſer, and the firſt ſinger in the ſerious opera ever ſince the year 1764, began his vocal career by the part of Tithonus, in which he had the moſt brilliant ſucceſs, and ever ſince that time he has continued to merit new favour.

"He is the ſon of a country ſchoolmaſter, and was born in 1739. Having diſcovered early in his life a diſpoſition for muſic, he was received as a choriſter in the cathedral of Laon. It was there that he laid the foundation for becoming one of the firſt muſicians in Europe, by his aſtoniſhing manner of executing, at ſight, the moſt difficult muſic. It is wholly unneceſſary to extend our encomiums on his fine voice, which is ſo well known as to need no deſcription; we ſhall content ourſelves with obſerving, that ſuch a one, with all its perfections, was neceſſary to conſole the public for the loſs of the inimitable Jeliotte.

"M. le Gros was ſo well inſtructed in the firſt principles of muſic by the maitre de chapelle at Laon, that he has ſometimes attempted compoſition; and has even produced in partnerſhip with M. Deſormery, an act of an opera which had ſome ſucceſs. We know other works of his that would merit ſtill more praiſe.

"In 1777 he undertook the direction of the *Concert Spirituel*, and his efforts to render that eſtabliſhment intereſting and worthy of the patronage of the public, has hitherto been juſtly crowned with ſucceſs; as he neither ſpared trouble nor expence in engaging the firſt muſicians in Europe of every kind to exhibit their talents at theſe concerts.

"His zeal, abilities, profeſſional punctuality in the performance of his parts, his paſſion for his art, and his worth and good conduct, have juſtly rendered him one of the ſingers moſt beloved by the public.

All this may be very true, yet his ſtyle of ſinging remains offenſive to all but the natives of France.

Gros, a foreign money, in divers countries, anſwering to our groat.

Gros, a French weight, of the old ſyſtem, = 3 deniers or French penny-weights = 72 French grains = 87.7562 Engliſh grains = 3.8248 grammes of the new metrical ſyſtem = .012587 pounds avoirdupoiſe.

GROSBURG, in *Geography*, a town of Sileſia, in the principality of Breſlau; 15 miles S. of Breſlau.

GROSCA, a ſmall iſland in the Black ſea. N. lat. 44° 19'. E. long. 29° 14'.

GROSE, Francis, in *Biography*, was born about the year 1731; his father was a jeweller at Richmond, who, at his death, in the year 1769, left the ſubject of this article an independent fortune, which he ſoon ſquandered away. His wants awakened in him a deſire to employ his talents in literary purſuits. He had received an excellent education, and poſſeſſed beſides a taſte for drawing, which induced him to commence his "Views of Antiquities in England and Wales." This work, which was the ſource both of reputation and profit, he completed in the year 1776; and in the following year he added two other volumes to them, which include the iſlands of Guernſey and Jerſey. In 1789 he paid a viſit to Scotland, and in 1790 began to publiſh, in numbers, his views taken in that country. He next proceeded to Ireland, with the view of giving a ſimilar deſcription of that country; but on the 6th of May, 1791, he was ſeized with an apoplectic fit and expired. He was buried at Dublin. He was an ingenious and pleaſant writer, and a remarkably good natured and facetious man. He was author of many other works beſides thoſe already mentioned, as "A Treatiſe on Ancient Armour and Weapons;" "A Claſſical Dictionary of the vulgar Tongue;" "Military Antiquities, being a Hiſtory of the Engliſh Army from the Conqueſt to the preſent Time," &c. &c.

GROSEN, in *Geography*, a town of the duchy of Courland; 28 miles S. of Goldingen.

GROS-FA, *Fr.* certain old muſic, conſiſting of breves, ſemibreves, and minims, was formerly ſo called in France. See Alla-breve.

GROSIO, in *Geography*, a town of the Valteline; 12 miles S. W. of Bormio.

GROSLEY, Peter John, in *Biography*, a lawyer and polite writer, the ſon of an advocate at Troyes, was born in 1718. He was brought up to the bar, and became an advocate in parliament, but his taſte for general literature rendered him more known than his profeſſional abilities. He was fond of foreign travel, and twice viſited Italy and England, he went likewiſe to Holland, and made annual viſits to the capital, where he was received in the beſt ſocieties. He preſented to his native city ſeveral marble buſts of eminent men born there. He died at Troyes in 1785, leaving behind him ſeveral valuable works, of which the principal are "Recherches pour ſervir á l'Hiſtoire du Droit François," 1752; "Vie des Frères Pithou," which gives an intereſting account of theſe friends of literature. "Obſervations de deux Gentil-hommes Suedois ſur l'Italie," 4 vols. 12mo.; "Londres," in three volumes, the reſult of obſervations made in his viſits to England, which are ſaid to be deſerving of much notice, though mixed with the miſtakes of a foreigner. "Eſſais Hiſtoriques ſur la Champagne;" "Ephemerides Troyennes." He had a ſhare in the "Memoires Academ. de Troyes," and the laſt tranſlation of Davila.

GROSS, Nicholas le, a learned French prieſt, was born at Rheims in the year 1675. Here he received the elementary parts of a learned education, and at the univerſity he diſtinguiſhed himſelf by his proficiency in the learning of the times, particularly in rhetoric and philoſophy. In 1694 he was appointed claſſical tutor in the college of the univerſity: the duties of this office he performed with great diligence, which, however, did not prevent him from purſuing with ardour and avidity his theological ſtudies, to which he was zealouſly attached. He was elected rector and afterwards prior of the univerſity. In the year 1700 he was ordained prieſt, and created a doctor two years after. He obtained much preferment in the church, and was at length made canon of the collegiate church at Rheims. He now devoted much of his time to the gratuitous inſtruction of a number of young perſons in the claſſics, philoſophy, and theology, and uſing, at the ſame time, every means to form their minds to the love of piety and virtue. As a diſputant he entered warmly into the diſcuſſion relative to the bull "Unigenitus," to which he was an active and ſpirited opponent. His zeal in this cauſe provoked the reſentment of the archbiſhop, M. Mailly, who excommunicated him, and even obtained a lettre de cachet to ſecure his perſon. M. le Gros obtained information of the fact in good time, and withdrew into Holland, where he continued till the death of Lewis XIV. In 1716 he returned to his canonry, and was in a ſhort time afterwards deputed to go to Paris, where he delivered a courſe of ſermons, which was attended by very crowded auditories. About the year 1720 he was perſecuted by the Jeſuits and the court on account of his zeal for Janſeniſm; a new lettre de cachet was iſſued for his apprehenſion, and for his baniſhment to the frontiers of Spain. He fortunately evaded the purſuit of the officers, and after remaining concealed

feveral years in France, he embraced an opportunity of retiring into Holland. Here he lived the laſt twenty-five years of his life, and obtained a high reputation as a learned theologian. He died in the year 1751, aged about 76. Independently of his controverſial writings, he left behind him "A tranſlation of the Bible;" "The Chriſtian's Manual;" and other valuable theological works, and ſome pieces againſt uſury.

Gross, or *Groſſus*, in our *Ancient Law Writers*, denotes a thing abſolute, and not depending on another. Thus, *villain in groſs*, *villanus in groſſo*, was a ſervant who did not belong to the land, but immediately to the perſon of the lord; or a ſervile perſon not appendant or annexed to the land or manor, and to go along with the tenures as appurtenant to it; but like other perſonal goods and chattels of his lord, at his lord's pleaſure and diſpoſal.

Gross, *Advowſon in*. See Advowson.

Gross-*Bean*, in *Zoology*, a name by which we commonly call the *coccothrauſtes*, called alſo at other times the *haw-finch*. This is the *loxia coccothrauſtes* in the Linnæan ſyſtem.

Gross, *in common*. See Common.

Gross *Weight*, is the weight of merchandizes and goods, with their duſt and droſs, as alſo of the bag, caſk, cheſt, &c. wherein they are contained; out of which groſs weight allowance is to be made of tare and tret.

Gross *Average*. See Average.

Gross is alſo uſed for the quantity of twelve dozen.

GROSSA, a groat. "Conceſſa eſt regi una groſſa, quæ continet quatuor denarios, de quolibet viro et muliere." Knighton, ann. 1378.

Grossa, in *Geography*, an iſland in the Adriatic, twenty-five miles long and two wide, near the coaſt of Dalmatia. N. lat. 44° 18'. E. long. 15° 7'.

GROSSE Isle, an iſland ſituated in the river Detroit, in Upper Canada; containing ſeveral thouſand acres of excellent land, and plenty of good wood, in a high ſtate of improvement.

Grosse, *Iſle la*, the name given by the Canadians to the Michilimachinac.

GROSSETO, a town of Etruria, the ſee of a biſhop, ſuffragan of Sienna, on a branch of the Ombrone; 14 miles E. S. E. of Piombino. N. lat. 42° 49'. E. long. 11° 4'.

GROSSETTESTE, or Grosthead, Robert, in *Biography*, was born at Stradbrook, in Suffolk, about the year 1175. Of the early part of his life nothing is known, but being qualified for an univerſity courſe, he was admitted at Oxford, where he ſoon diſtinguiſhed himſelf by his proficiency in different branches of literature, particularly in the Greek language, at that time but little known in the country. From Oxford he went to Paris, and made himſelf maſter of the French language. Upon his return he read lectures at Oxford on philoſophy and theology, and he was preſented with the prebend of Lincoln by the biſhop of that ſee, Hugh de Welles, who was, to him, a generous patron. Upon the death of this prelate he was appointed to ſucceed him, but he had ſcarcely taken poſſeſſion of the biſhopric, when a mandate, arriving from Rome, enjoined him to admit a nephew of the pontiff, who was under age, to the firſt canonry that ſhould become vacant in the ſee of Lincoln. This mandate he was reſolved to reſiſt, and accordingly ſet out to Rome, hoping that he ſhould be able to ſatisfy the pontiff that he could not, and ought not, to comply with the demand. He expected, likewiſe, that he ſhould be able, by perſonal application, to obtain relief from ſome exactions by which he, in common with the other Engliſh prelates, was burthened. With regard to the immediate objects of his journey he was unſucceſsful, and upon his return he wrote a letter to the pope's ſecretary, in which, while he acknowledged a moſt reſpectful ſubmiſſion to the apoſtolic orders of the Roman ſee, yet he ſaid that he ſhould deem it his bounden duty to reſiſt thoſe commands that tended to the deſtruction and not the edification of the church. He ſaid he would induct no perſons to incomes, appointed for the maintenance of paſtors, who were not capable of executing their offices, and that he ſhould conſider any commands to the contrary impoſſible to have been iſſued by the holy ſee. He then ſpoke in a different tone, and reflected moſt ſeverely on the degeneracy of the manners of the modern popes from the ſanctity of their predeceſſors, and ſolemnly adjured his holineſs to correct thoſe enormous vices, which, flowing from the court of Rome, as from a poiſoned fountain, contaminated the whole Chriſtian church. The pope threatened our worthy prelate with a heavy vengeance; he had been accuſtomed to iſſue his bulls, but never before to be admoniſhed by a perſon of inferior rank, and took every opportunity in his power of haraſſing him during the remainder of his life. The Engliſh biſhop had, however, counted the coſt before he undertook to reaſon with the biſhop of Rome, and he never once abandoned the high ground on which he ſtood; he was fortified by the principles of rectitude and honeſty, and was generally ſucceſsful in reſiſting the powers brought againſt him, and in preventing encroachments upon the Engliſh church. He died at Buckden in the year 1253, having preſided over the ſee of Lincoln nearly twenty years, with the moſt vigilant attention, and unremitting application, taking the greateſt care to have the parochial churches well ſupplied, and ſetting before his clergy an excellent example of the manner in which the paſtoral duties ought to be diſcharged. He had a clear head and a pure heart. He was undaunted in a right cauſe, his integrity was incorruptible, and the ſanctity of his manners was unimpeachable. He was the patron of learning and learned men, and his own acquirements are reckoned very extraordinary, conſidering the times in which he lived. As a friend he was eaſy of acceſs, and in company he was lively and affable; to thoſe who needed his help he was beneficent, and he was kind and hoſpitable to all. As a churchman his notions were very elevated; his biographer, Dr. Pegge, ſays of him, "he ſoars ſo high in his ideas concerning the privileges and prerogatives of the clerical order, that he even leaves archbiſhop Becket far behind him." He left numerous treatiſes on theological, philoſophical, and miſcellaneous ſubjects, ſome of which are printed, and the reſt are extant in MS. Among the former are "Opuſcula Varia," publiſhed at Venice in 1504: "Compendium Sphæræ Mundi:" "Commentarius in Lib. poſter. Ariſtotelis;" "Diſcourſes;" and "Letters."

GROSSO, *Ital. Grand*, great: as *concerto groſſo*, in *Muſic*, a grand concerto. Pl. *Concerti groſſi*, grand concertos. Trombone groſſo, great or double trumpet. Baſſo groſſo, a double baſe.

GROSSULARIA, in *Botany*, a Latin name, of no good authority, for the gooſeberry, borrowed undoubtedly from *groſſula*, a little unripe fig. Tournefort retained it for the whole genus of gooſeberries and currants, the *Ribes* of Linnæus, in which he and Plumier included the very diſtinct and diſſimilar South American genus, *melaſtoma*. See Melastoma and Ribes.

GROTESQUE, in *Painting* and *Sculpture*, a word adopted from the French, and ſignifies, together with the Italian *groteſca*, the repreſentation of deformed and monſtrous objects, in which the utmoſt extravagance of imagination is allowed to revel, without regard to nature or probability.

bability. A taſte and ſtyle of ornament which has been employed to decorate walls, ceilings, furniture, &c. ever ſince the diſcovery of antique, monumental paintings, and ſculptures in ſubterranean chambers near Rome, and throughout Italy, which were adorned by it in the times of the ancient Romans. Hence the name is derived, the Italians calling all ſuch places *grotte*.

Its origin is diſcernible in the Egyptian hieroglyphic writing, where the heads and limbs of men and beaſts are attached to blocks of ſtone, to vaſes, or to foliage, &c. thereby characterizing the inclinations and the powers of the Deity, or perſon whoſe hiſtory they record, or whoſe peculiar tranſactions they are intended to preſerve in the remembrance of future ages.

With the Egyptians it remained rude and unpoliſhed; but when the Greeks adopted it, they made an ornamental uſe of it, and it became a medium to exhibit their general knowledge of nature. The taſte with which they united in one form, not only parts of various animals, but objects ſo totally diverſe in their nature and appearance, as the productions of the animal and vegetable kingdoms, is in the higheſt degree delightful to contemplate. The formation of chimerical beings, as the dragon, the ſphinx, the griffin, &c. owe their origin to this taſte; which received much of its force and intereſt in heathen days, from the mythological enigmas couched under theſe compound forms. Such is the character of that ornament ſo common on Egyptian ſtructures, the winged ſerpent ſurrounding an egg. Now, that theſe myſterious emblematic meanings are diſregarded, and no longer treated with reverence, groteſque painting and ſculpture are continued in uſe merely becauſe the forms they produce are pleaſing to the eye; and although the underſtanding is inſulted by them, yet ſuch is the power of the beauty of form, that we are gratified by it, in ſpite of our reaſon.

Groteſque work is at preſent chiefly confined in its application to monumental ſculpture, where it retains ſomewhat of its emblematic origin; to carvings or painting of furniture, wherein beauty of ornament is principally ſought for in it; and ſometimes it is employed in painting and ſtucco on the interior of rooms, but rarely to any great extent; a better and more ſimple taſte having in great meaſure ſuperſeded it.

Thoſe who wiſh to make themſelves acquainted with it, will find the beſt exemplars on ancient Greek ſarcophagi, altars, vaſes, friezes, &c. of which Piraneſi and Rocchegiani have given an ample ſtore to the public in their valuable works. Mr. C. H. Tatham has given likewiſe a taſteful and judicious ſeries of examples of this kind, in his collection of etchings of ornamental architecture from the antique at Rome. Le Roy's, Le Pôtre's, and many other works of the like kind, may alſo be conſulted with advantage.

We alſo extend the word groteſque to any thing whimſical, or wildly pleaſant, in a perſon's dreſs, diſcourſe, &c. Maſquerade habits are the more valued, the more groteſque they are. Our theatres preſent us with entertainment in groteſque characters, *i. e.* perſons quaintly dreſſed; as harlequins, ſcaramouches, &c. Planudes has given us a very groteſque picture of Æſop. Arioſto and the Italian poets are full of groteſque deſcriptions.

GROTESQUE is a light ſtyle of ornament, conſiſting of mixed repreſentations of foliage, animals, utenſils, implements of war, &c. or any mixture of theſe. This ſtyle was uſed by the ancient Romans in the decorations of their palaces, villas, baths, amphitheatres, temples, and ſometimes even in their tombs, and chiefly to be found in the vaulted apartments of their ruined ſtructures, moſtly covered with rubbiſh, which have been cleared away by the modern Italians, who gave theſe ornaments the name of grotte, and hence the modern term groteſque, and the Engliſh term grotto, ſignifying a cave.

This beautiful ſtyle of ornament was employed by Raphael and others in the decorations of the Logias, of the Vatican, the villas of Madama, Pampli, Caprarola, the old palace at Florence, and indeed in the moſt elegant finiſhings of modern Italy; and there is little doubt but the remains were much more ample in the time of Raphael and others, who firſt introduced them, than are now to be found.

GROTIUS, HUGO, in *Biography*, was born at Delft, April 10th, 1583. His father, John de Groot, was a learned and reſpectable citizen of Delft, of which he was burgo-maſter and ſheriff, and alſo curator of the univerſity of Leyden. Hugo was remarkable, from his earlieſt years, for great brilliancy of parts, and his application was as indefatigable as his talents were ſuperior. At the age of eight years, he compoſed Latin elegiac verſes, and at fourteen he maintained public theſes in mathematics, law, and philoſophy. He had been under the tuition of Francis Junius, and now the great Scaliger, ſtruck with the abilities of Hugo, condeſcended to direct his ſtudies. His reputation was quickly eſtabliſhed, and he is mentioned, at this early period, by the principal ſcholars of the age, as a prodigy of learning, and as one who was deſtined to make a conſpicuous figure in the republic of letters. In 1598, he accompanied Barneveldt, the ambaſſador extraordinary of the States, in a journey to France. Here he was introduced to Henry IV., who gave him a polite reception, and preſented him with his picture and a gold chain. He took the degree of doctor while he was in France; and during his reſidence there he received many attentions from men of the firſt eminence for rank and learning. He was deſirous of an interview with De Thou, whom, of all perſons, he moſt highly eſteemed in that country; but this he was unable to accompliſh. Upon his return, he addreſſed a complimentary letter to the venerable preſident, which was the commencement of an intimate correſpondence between them. In 1599, Grotius, who was deſtined to the profeſſion of the law, pleaded his firſt cauſe at Delft. He now publiſhed his "Capella," a work which was received with great admiration by the learned. This was followed by a Latin tranſlation of a treatiſe by Stevinus, containing directions for finding a ſhip's place at ſea. His edition of the "Phenomena of Aratus," which he publiſhed in the year 1600, obtained for him a high reputation for learning with Scaliger, De Thou, and Lipſius, and other great men of the age. We ſhall not be able to notice all the works of this great man, but it may be obſerved, that he had now, though only ſeventeen years of age, ſo thoroughly eſtabliſhed his character as a writer, that he was choſen hiſtoriographer to the United Provinces, in preference to ſeveral learned men who were candidates for the office. After this, the office of advocate-general of the treaſury for Holland and Zealand was conferred upon him unanimouſly. In 1608 he married Mary Reigerſberg, a lady deſcended from one of the beſt families in Zealand, and who, as we ſhall ſee farther on, was in every reſpect worthy of the man who had ſelected her, as the partner of his joys and his cares. In the following year he publiſhed his "Mare Liberum," aſſerting the right of the Dutch to trade to the Eaſt Indies, in oppoſition to the claims of Portugal. It alſo laid claim to the general liberty of the ſeas, in oppoſition to the demands of this country, which produced an anſwer from the learned Selden. His next work was a treatiſe "De Antiquitate Reipublicæ Batavæ;" the object of this performance was to prove the continued freedom and independence of the Batavian nation from the Roman times. A boaſt, alas! no

longer to be made, the tyrant of the continent having annihilated the name, as well as the independence of the Batavian ſtates. Theſe now make a part only of the French empire: the ſame mighty potentate is contending for what he calls the liberty of the ſeas, by which he unqueſtionably means the ruin of Britain's independence, but we truſt that we have a multitude of practical Seldens, that, under providence, will ſay, hitherto thou mayeſt come, but no farther. In the year 1613, he was offered the poſt of penſioner of Rotterdam, which he accepted only on the condition that it ſhould be permanent during his life. This was readily acceded to, and the poſt gave him a ſeat in the aſſembly of the ſtates of Holland, and afterwards in the States-General. About this time ſome differences ſubſiſted between the Dutch and Engliſh, on account of the claim made by the latter of an excluſive right of fiſhery in the Greenland ſeas. Grotius was ſent over to adjuſt the matter in diſpute: he was received with kindneſs and reſpect by king James, and ſhewed himſelf an able defender of what he regarded as his country's rights. Here he contracted a friendſhip with the celebrated Caſaubon, then reſiding in England, who reſembled him by the depth of his erudition, and by his ardent deſire of procuring a fraternal union among Chriſtians. Grotius was early inſtructed in the principles of Arminianiſm, and he was now connected with the grand penſionary Barneveldt, whoſe brother he had ſucceeded in his poſt at Rotterdam. Hence he became of the party of Remonſtrants in the church, and of ſtrict republicans in the ſtate. After his return from England, he was appointed to draw up the edict of the States intended to reſtore tranquillity, but it was done with ſo much toleration as to give offence to the oppoſite party, which was ſupported by the majority of the people and clergy. He now became deeply involved in the political diſputes of the day, and was, by order of prince Maurice, arreſted, together with the grand penſionary. They were thrown into priſon at the Hague, and ſo cloſely confined, that even the wife of Grotius was denied acceſs to him, although he was dangerouſly ill. The city of Rotterdam petitioned for the liberation of their penſionary; but the prince refuſed to liſten to their prayers. He had contrived to overthrow the Arminian party, to depoſe and baniſh its miniſters, and now he determined to carry his plans farther, and to deſtroy Barneveldt. He accordingly brought him to trial, and, from a mock trial, he was obliged to aſcend the bloody ſcaffold. Grotius was intended as the next victim, but he eſcaped with his life, and was ſentenced to perpetual impriſonment. The place of his confinement was the fortreſs of Louveſtein, near Gorcum, in South Holland. His wife, with much difficulty, obtained permiſſion to be his fellow-priſoner, and in one of his Latin poems he has deſcribed moſt pathetically the conſolation which her preſence afforded him in his priſon-gloom. The greatneſs of her mind elevated her above feminine lamentation, and her ſole ſtudy was to alleviate the rigour of his fate. He now ſat down to ſtudy the law, with all the ardour of which his great mind was capable. Some part of his time was devoted to morality, and he ſpent his Sundays in reading arguments in favour of the Chriſtian revelation, and in drawing up notes on the New Teſtament. It was in priſon that he compoſed the ground-work of his famous work "De Veritate." He alſo wrote in Dutch "Inſtitutions of the Laws of Holland," thus conſulting the good of his countrymen, even while ſuffering under their hardſhips and ſeverity. After he had been kept in priſon a year and a half, he was delivered by the advice and contrivance of his wife. She perſuaded him to conceal himſelf in a large cheſt, which ſhe ſent away under the pretence of ſending off a load of books, to prevent Grotius from killing himſelf with hard ſtudy. A ſervant, who was entruſted with the ſecret, accompanied the cheſt in a boat to Gorcum, and got it conveyed to a friend's houſe. Grotius quitted it uninjured, and immediately dreſſing himſelf like a maſon, and taking his rule, trowel, and other implements of the trade, he paſſed through the market-place, and ſtepping into a boat, was tranſported to Antwerp. This happy eſcape was effected on the 22d of March, 1621. His wife, in the mean time, kept up the belief that he was confined to his bed by ill health, till having heard of his ſafety, and that he was out of the reach of his perſecutors, when ſhe avowed the fact. She was immediately detained in cloſe cuſtody by the enraged commandant, but a petition to the States-General procured her diſcharge. There were not wanting ſome baſe ſpirits who voted for continuing her impriſonment, but the majority were aſhamed of puniſhing a woman for an act of conjugal fidelity, which could not but command univerſal applauſe.

He retired to France, and was furniſhed with letters of recommendation by Du Maurier, ambaſſador of that country at the Hague. He arrived at Paris in the month of April, where he met with a moſt gracious reception from that court, and from the king, Lewis XIII. who ſettled a penſion on him. The hatred of ſome of his countrymen followed him wherever he went, and they ſpread all ſorts of calumnies againſt him, which, in the true ſpirit of Chriſtianity, he generouſly repaid, by ſpeaking of his country with the attachment of a zealous citizen. He was particularly hurt by a report which they raiſed, of his intention to ſolicit a pardon of the States. This he publicly contradicted, obſerving, that it was not likely he ſhould acknowledge an offence now he was at liberty, which he refuſed to do while in priſon. In France he compoſed his celebrated work "De Jure Belli et Pacis." In the year 1625, the death of Maurice, prince of Orange, raiſed the hopes of Grotius, that he might be reſtored to his country. With the ſucceſſor of the prince, Frederic Henry, Grotius had been on intimate terms; they had even maintained a correſpondence with one another at the period when Grotius was moſt unpopular, but prudence on the part of the new prince prevented him from taking any decided meaſures in favour of the illuſtrious exile. The glory which he acquired by his book "De Jure Belli et Pacis," printed this ſame year, might recompenſe him for the diſappointment. It was received with admiration by the learned throughout Europe, was commented upon and criticiſed, tranſlated, and had all the honours of a work calculated to lead men to think deeply and freely upon a very important topic. When cardinal Richelieu became prime miniſter, he wiſhed to engage Grotius in his ſervice, and in that of France; but the noble-minded exile could not forget his country, and becauſe he would not give himſelf ſolely to France, he was made to feel all the mortifications of a dependant out of favour. He determined, after eleven years' exile, to return to Holland; but in a ſhort time he found that the animoſities of his enemies had not ſubſided, and his friends, timid and daſtardly, were afraid to ſhew him that reſpect and attachment to which he was juſtly entitled. A reward was offered for his apprehenſion, and the prince, who did not dare to avow himſelf his defender, refuſed to take meaſures for his ſecurity. Grotius, therefore, was obliged to ſeek an aſylum at Hamburgh, where he reſided two years. In 1634, queen Chriſtina of Sweden made him her counſellor, and ſent him ambaſſador into France. Thus aſſured of an honourable ſituation, he wrote to the prince of Orange and the States-General, that he wiſhed no longer to be conſidered as a Dutchman;

Dutchman; the wrongs which he had received from a tyrannical government, and the ſlights which he had experienced from thoſe who ought to have afforded him an aſylum againſt his avowed enemies, ſeem to have made a deep and laſting impreſſion on his mind, and to have rendered him indifferent to his country's concerns. After having diſcharged the duties of this office above eleven years, he obtained his recal, and ſet out, by way of Holland, to give to the queen an account of his miſſion. He left France in the ſpring of 1645, and proceeded to Holland, where he was now received with great honour. The city of Amſterdam entertained him at the public expence, and fitted out a veſſel to convey him to Hamburgh: thence, by the way of Lubec, where he had every mark of reſpect ſhewn him, he entered Sweden, and repaired to Stockholm. Chriſtina was eager to ſee him, not only as her ſervant, but as a man, highly diſtinguiſhed in the republic of letters, and ſhe gave him a long audience, with which he was well ſatisfied. He hoped for a reward for his long ſervices, but received only compliments; he would willingly have entered on ſome new employment, but could obtain none: he requeſted therefore a paſſport, that he might return to his own country; this ſmall boon was refuſed, in the hope, that he would conſent to remain at the court of Sweden as counſellor to the queen. He at length ſet out without the formality of a paſſport, but the news of his departure being carried to Chriſtina, ſhe ſent after him to requeſt another interview, which he readily granted, and this paſſed ſo amicably, that ſhe preſented him with a conſiderable ſum in money, and a handſome ſervice of plate. A veſſel was now provided for his conveyance, on board of which he embarked on the 12th of Auguſt. They had ſoon to encounter a violent ſtorm, which obliged him to go on ſhore, at a ſmall diſtance from Dantzic. From thence he travelled by land to Roſtock, where he died on the 28th of Auguſt, 1645. His body was carried to Delft, to be interred in the ſepulchre of his anceſtors. Three ſons, one daughter, and his wife ſurvived him. Few writers have diſtinguiſhed themſelves in more branches of literature than Grotius. "His great work, "On the Rights of Peace and War," was the firſt attempt to ſyſtematiſe the law of nations, which, though imperfect, is perhaps the moſt complete that the world has yet owed, at ſo early a ſtage in the progreſs of any ſcience, to the genius and learning of one man." As a divine, Grotius is known by his work "On the Truth of the Chriſtian Religion," which has been tranſlated into all languages. He is alſo greatly eſteemed as a commentator on the Scriptures.

GROTON, in *Geography*, a town of America, in the county of Grafton, New Hampſhire, 15 miles N.E. of Dartmouth college, containing 391 inhabitants.—Alſo, a townſhip in Caledonia county, Vermont, on Connecticut river, nine miles N.W. of Stephen's fort on the ſame river, containing 248 inhabitants.—Alſo, a poſt-town in Middleſex county, Maſſachuſetts, 35 miles N.W. of Boſton; containing 1802 inhabitants.—Alſo, a townſhip in New London county, Connecticut, ſeparated by Thames river from New London, to which it formerly belonged. It was incorporated in 1705, and conſiſts of two pariſhes, containing 4372 inhabitants.

GROTSKAW, a town of Servia; 15 miles S. of Belgrade

GROTTA, a town of Italy, in the department of the Upper Po; ſeven miles N.W. of Cremona.

GROTTAGLIA, a town of Naples, in the province of Otranto; nine miles E. of Tarento.

GROTTA MENARDA, a town of Naples, in Principato Ultra; 12 miles E.S.E. of Benevento.

GROTTA St. LORIA, a town of Naples, in Capitanata; 12 miles W. of Manfredonia.

GROTTARI, a town of Naples, in Calabria Ultra; ſix miles N. of Gierace.

GROTTGAU, or GROTTKAU, a town of Sileſia, and capital of a circle in the principality of Neiſſe, ſituated on the river Neiſſe; 14 miles N. of Neiſſe. N. lat. 50° 37'. E. long. 17° 20'.

GROTTO, or GROTTA, in *Natural Hiſtory*, a large deep cavern, or den in a mountain or rock.

The word is Italian, *grotta*, formed, according to Menage, &c. from the Latin *crypta*: Du Cange obſerves, that *grotto* was uſed in the ſame ſenſe in the corrupt Latin.

The ancient anchorets retired into dens and grottos, to apply themſelves the more attentively to meditation.

Okey-hole, Elden-hole, Pool's-hole, and the Devil's A—ſe in the Peake, are famous among the natural caverns or grottos of our country.

The entrance to Okey-hole, on the ſouth ſide of Mendip-hills, is in the fall of thoſe hills, which is beſet all about with rocks, and has near it a precipitate deſcent of near twelve fathoms depth, at the bottom of which there continually iſſues from the rocks a conſiderable current of water. The naked rocks above the entrance ſhew themſelves about thirty fathoms high, and the whole aſcent of the hill above is about a mile, and is very ſteep. As you paſs into this vault, you go at firſt upon a level, but advancing farther, the way is found to be rocky and uneven, ſometimes aſcending, and ſometimes deſcending. The roof of this cavern, in the higheſt part, is about eight fathoms from the ground, but in many particular places it is ſo low, that a man muſt ſtoop to get along. The breadth is not leſs various than the height, for in ſome places it is five or ſix fathoms wide, and in others not more than one or two. It extends itſelf in length about two hundred yards. People talk much of certain ſtones in it, reſembling men and women, and other things, but there is little matter of curioſity in theſe, being only ſhapeleſs lumps of a common ſpar. At the fartheſt part of the cavern there is a good ſtream of water, large enough to drive a mill, which paſſes all along one ſide of the cavern, and at length ſlides down, about ſix or eight fathoms, among the rocks, and then preſſing through the clefts of them, diſcharges itſelf into the valley.

The river within the cavern is well ſtored with eels, and has ſome trouts in it; and theſe cannot have come from without, there being ſo great a fall near the entrance. In dry ſummers, a great number of frogs are ſeen all along this cavern, even to the fartheſt part of it; and on the roof of it, at certain places, hang vaſt numbers of bats, as they do in almoſt all caverns, the entrance of which is either level, or but ſlightly aſcending or deſcending; and even in the more perpendicular ones they are ſometimes found, provided they are not too narrow, and are ſufficiently high. The cattle that feed in the paſtures, through which this river runs, have been known to die ſuddenly ſometimes after a flood: this is probably owing to the waters having been impregnated, either naturally or accidentally, with lead-ore. Philoſoph. Obſerv. N° 2. p. 2.

In the Philoſophical Tranſactions, N° 480. p. 223. we have an account of a ſubterranean grotto, or cavern, near Weredale, about twenty miles ſouth-weſt of Newcaſtle.

Elden-hole is a huge profound perpendicular chaſm, three miles from Buxton, ranked among the natural wonders of the Peak. Its depth is unknown, and is pretended to be unfathomable. Cotton tells us he ſounded 384 yards; yet the plumbet ſtill drew. But he might eaſily be deceived, unleſs

unleſs his plumbet was very heavy; the weight of a rope of that length might well make the landing of the plumbet ſcarcely perceivable. Phil. Tranſ. N° 407. p. 24.

Peak's-hole, and Pool's-hole, called alſo the Devil's A—ſe, are two remarkable horizontal ſprings under mountains; the one near Caſtleton, the other juſt by Buxton. They ſeem to have owed their origin to the ſprings which have their current through them: when the water had forced its way through the horizontal fiſſures of the ſtrata, and had carried the looſe earth away with it, the looſe ſtones muſt fall down of courſe: and where the ſtrata had few or no fiſſures, they remained entire; and ſo formed there very irregular arches, which are now ſo much wondered at. The water which paſſes through Pool's-hole is impregnated with particles of lime-ſtone, and has incruſted the whole cavern in ſuch a manner that it appears as one ſolid rock. Martyn, in Phil. Tranſ. N° 407. p. 27. et ſeq.

In grottos are frequently found cryſtals of the rock, ſtalactites, and other natural conglaciations, and thoſe often of an amazing beauty.

M. Homberg conjectures, from ſeveral circumſtances, that the marble pillars in the grotto of Antiparos vegetate, or grow. That author looks on this grotto as a garden, whereof the pieces of marble are the plants; and endeavours to ſhew, that they could only be produced by ſome vegetative principle. Mem. Acad. anno 1702.

At Foligno in Italy, is another grotto, conſiſting of pillars and orders of architecture of marble, with their ornaments, &c. ſcarcely inferior to thoſe of art; but they all grow downwards: ſo that if this too be a garden, the plants are turned upſide down. Mem. de l'Acad. anno 1711.

The Zirchinitzer-ſea, or lake, in Carniola, famous for being full of water, fiſh, &c. the beſt part of the year, and quite dry, and bearing graſs, corn, &c. the reſt proceeds from ſome ſubterraneous grotto, or lake; as it is made highly probable by Mr. Vavaſor. Phil. Tranſ. N° 191.

GROTTO, in *Geology*, is a term frequently applied to the natural caverns, opens, and ſhake-holes, which are met with in thick ſtrata, or rocks of lime-ſtone, as in the mountainous parts of Derbyſhire, in Mendip hills, and other places. The immenſely large empty ſpaces which are thus found at conſiderable depths below the ſurface, have much puzzled the learned to account for their formation: ſome have ſuppoſed, with little appearance of probability, that the lime-ſtone which once occupied theſe grottos has been diſſolved and waſhed out by the ſprings and ſtreams of water frequently found running through them. Mr. Farey, who has paid much attention to this ſubject, and prepared a liſt of all the principal caverns in or near to Derbyſhire, for his report on that county, is of opinion that the mineral veins both of the rake and pipe kind, have all had the ſame origin with the caverns in Derbyſhire, *viz.* the great ſhrinking of the maſs, as of lime-ſtone, at the time, or ſince their induration: while the baſaltic ſtrata, or toad-ſtone rocks, which inter-lay them, ſeem not to have been ſuſceptible of the ſame contraction; and hence the mineral veins frequently have a ſole and lid-ſtone of ſolid toad-ſtone, and ſometimes the caverns, or empty pipe veins, have a roof, or floor, of the ſame kind. The roofs of the wider caverns, like the entrance to Peak-hole at Caſtleton, are compoſed of a rude or imperfect cryſtallization of calcareous matters, as diſtinct from the lime-ſtone rocks in which ſuch caverns are ſituate, as the riders and vein-ſtuff of the mineral veins are from the ſame rocks. The ſides, or walls of the caverns, are alſo for the moſt part coated with ſimilar vein-ſtuff, and ſo are the faces of the greater part, if not all, of the natural cliffs, or façades of lime-ſtone, in theſe diſtricts (ſee Phil. Mag vol. 31. p. 39.); which coatings have cemented the different beds of ſtone together, like one vaſt ſtone, or unſtratified rock, as may be ſeen in the face of the entrance to Caſtleton cave, of Matlock, High-Tor, &c. &c. and have deceived many perſons as to the ſtructure of theſe rocks. The water continually percolating through the roofs of moſt of the caverns has, and ſtill is accumulating ſtalactites pendent from the roofs, and ſtalagmites on the floor under the drippings of them: many of theſe have met, and formed numerous groteſque pillars, ſupporting the roof as it were. The more minute and beautiful ſtalactites and ſtalagmites have long ſince been ſtripped from the acceſſible caverns of this diſtrict to ſatisfy vulgar curioſity. Bagſhaw's, or Mule-ſpinner cavern, in Bradwell, near Caſtleton, lately diſcovered, and particularly Merlin's cave in Eyamdale, the private property of William Longſdon, eſq., are the places where the moſt perfect ſtalactites are now to be ſeen.

We have ſeveral grottos famous in natural hiſtory; as

GROTTO *del Cani*, a little cavern near Pozzuoli, four leagues from Naples, the ſtreams whereof are of a mephitical, or noxious quality; whence alſo it is called *bocca venenoſa*, the poiſonous mouth. See MEPHITIS.

Two miles from Naples, ſays Dr. Mead, juſt by the Lago de Agnano, is a celebrated moſeta, commonly called *la Grotta del Cani*, and equally deſtructive to all within the reach of its vapours.

It is a ſmall grotto, about eight feet high, twelve long, and ſix broad; from the ground ariſes a thin, ſubtile, warm fume, viſible enough to a diſcerning eye, which does not ſpring up in little parcels here and there, but in one continued ſtream, covering the whole ſurface of the bottom of the cave; having this remarkable difference from common vapours, that it does not, like ſmoke, diſperſe itſelf into the air, but quickly after its riſe falls back again, and returns to the earth; the colour of the ſides of the grotto being the meaſure of its aſcent: for ſo far it is of a darkiſh-green, but higher, only common earth. And as I myſelf found no inconveniency by ſtanding in it, ſo no animal, if its head be above this mark, is the leaſt injured. But when, as the manner is, a dog, or any other creature, is forcibly kept below it; or, by reaſon of its ſmallneſs, cannot hold its head above it; it preſently loſes all motion, falls down as dead, or in a ſwoon; the limbs convulſed and trembling, till at laſt no more ſigns of life appear than a very weak and almoſt inſenſible beating of the heart and arteries; which, if the animal be left a little longer, quickly ceaſes too, and then the caſe is irrecoverable; but if it be ſnatched out, and laid in the open air, it ſoon comes to life again, and ſooner, if thrown into the adjacent lake.

The true explication of the noxious effects of this vapour may be ſeen under the articles *Fixed* AIR, AZOTE, DAMP, &c.

GROTTO *del Serpi* is a ſubterranean cavern near the village of Saſſa, eight miles from the city of Braccano, in Italy; deſcribed by Kircher thus:

The Grotta del Serpi is big enough to hold two perſons: it is perforated with ſeveral fiſtula apertures, ſomewhat in manner of a ſieve; out of which, at the beginning of the ſpring-ſeaſon, iſſues a numerous brood of young ſnakes, of divers colours, but all free of any particular poiſonous quality.

In this cave they expoſed their lepers, paralytics, arthritics, and elephantiac patients, quite naked; where the warmth of the ſubterraneous ſtreams reſolving them into ſweat, and the

the ſerpents clinging variouſly all around, licking and ſucking them, they become ſo thoroughly freed of all their vicious humours, that upon repeating the operation for ſome time, they become perfectly reſtored. This cave Kircher viſited himſelf, and found it warm, and every way agreeable to the deſcription given of it. He ſaw the holes, and heard a murmuring hiſſing noiſe in them. Though he miſſed ſeeing the ſerpents, it not being the ſeaſon of their creeping out; yet he ſaw a great number of their exuviæ, or ſloughs, and an elm, growing hard by, laden with them.

The diſcovery of this cave was by the cure of a leper going from Rome to ſome baths near this place; who, loſing his way, and being benighted, happened upon this cave; and finding it very warm, pulled off his clothes; and being weary and ſleepy, had the good fortune not to feel the ſerpents about him till they had wrought his cure. Muſeum Wormian.

The ſalutary effects of this cavern were probably of the ſame nature, and to be aſcribed to the ſame cauſe with thoſe of the Pyrmont and Spa waters, abounding with a great quantity of the gas, or fixed air, which lies alſo to a certain height on the ſurface of the ground; and whither diſeaſed perſons reſort, and find relief in a variety of diſorders. The antiſeptic ſalutary quality of this air is now ſufficiently known.

Grotto, *Milky*, *Crypta Lactea*, a mile diſtant from the ancient village of Bethlehem, is ſaid to have been thus denominated on occaſion of the bleſſed Virgin, who let fall ſome drops of milk in giving ſuck to Jeſus in this grotto. And hence it has been commonly ſuppoſed, that the earth of this cavern has the virtue of reſtoring milk to women that are grown dry, and even of curing fevers.

Accordingly, they are always digging in it, and the earth is ſold at a good rate to ſuch as have faith enough to give credit to the fable. An altar has been built on the place, and a church juſt by it.

Grotto is alſo uſed for a little artificial edifice made in a garden, in imitation of a natural grotto.

The outſides of theſe grottos are uſually adorned with ruſtic architecture, and their inſide with ſhell-work, foſſils, &c. finiſhed likewiſe with jets d'eaus, or fountains, &c.

A cement for artificial grottos may be made thus: take two parts of white roſin, melt it clear, and add to it four parts of bees' wax; when melted together add two or three parts of the powder of the ſtone you deſign to cement, or ſo much as will give the cement the colour of the ſtone; to this add one part of flour of ſulphur; incorporate all together over a gentle fire, and afterwards knead them with your hands in warm water. With this cement the ſtones, ſhells, &c. after being well dried before the fire may be cemented.

Artificial red coral branches, for the embelliſhment of grottos, may be made in the following manner: take clear roſin, diſſolve it in a braſs-pan; to every ounce of which add two drams of the fineſt vermilion: when you have ſtirred them well together, and have choſen your twigs and branches, peeled and dried, take a pencil and paint the branches all over whilſt the compoſition is warm; afterwards ſhape them in imitation of natural coral. This done, hold the branches over a gentle coal fire, till all is ſmooth and even as if poliſhed.

In the ſame manner white coral may be prepared with white lead, and black coral with lamp-black.

A grotto may be built, with little expence, of glaſs, cinders, pebbles, pieces of large ſtone, ſhells, moſs, ſtones, counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above deſcribed cement.

The grotto at Verſailles is an excellent piece of building. Solomon de Caux has an expreſs treatiſe of grottos and fountains.

GROTTOLA, in *Geography*, a town of Naples, in the Baſilicata; 4 miles S. W. of Matera.

GROVA, a town of Africa, on the Grain Coaſt; 10 miles N. W. of Cape Palmas.

GROVE, Henry, in *Biography*, was born at Taunton, in Somerſetſhire, in the year 1683. He was deſcended, both by his father and mother, from families of great reſpectability, and who had been remarkable for their ſteady attachment to religious liberty, and the rights of conſcience. Henry was formed to the love and practice of virtue, by the inſtructions and example of his parents. He was ſoon diſcovered to poſſeſs talents of a ſuperior order, and ſuch proficiency did he make in grammar learning that at fourteen years of age he was ſent to purſue his ſtudies under Mr. Warren of Taunton, with a view to the Chriſtian miniſtry. When he had completed the uſual courſe, under the ſuperintendance of this gentleman, he removed to London, and proſecuted his ſtudies under Mr. Rowe; here he was led to cultivate the Hebrew language, and here he embraced the Newtonian ſyſtem of philoſophy, in oppoſition to that of Deſcartes, to which his tutor ſteadily adhered. At this period he contracted an intimacy with Dr. Watts, which continued with mutual eſteem till his death; though on many points, warmly controverted in that day, as in this, they differed in opinion. In 1706 he ſucceeded his tutor, Mr. Warren, in the academy at Taunton, having previouſly commenced the office of preacher with ſingular reputation. The town of Taunton was now the place of his reſidence, and here he continued to preach for eighteen years to two ſmall congregations. His ſalary, as miniſter from both his charges, did not amount to 20*l.* a year, nevertheleſs he went through the duties with cheerfulneſs and aſſiduity, greatly beloved by thoſe who were brought up under his inſtructions. "An exact judgment," ſays his biographer, "a lively imagination, a warmth of devotion, and a rational and animated repreſentation of Chriſtianity, made his ſermons, delivered by a voice, which, though not ſtrong, was ſweet and well governed, generally admired." As an author, his firſt publication was a treatiſe entitled "The Regulation of Diverſions," this was printed in 1708, and ſoon after he engaged in a correſpondence with the celebrated Dr. Clarke, on the ſubject of the being and attributes of God. The doctor had drawn his proof from our neceſſary ideas of ſpace and duration, by which the mind of Mr. Grove was by no means ſatisfied; he wrote for an explanation, but after the interchange of ſeveral letters, the correſpondence was dropped with expreſſions of mutual eſteem. Mr. Grove next appeared as a writer in the Spectator, and is known to be the author of Nos. 588, 601, 626, and 635: the laſt was afterwards republiſhed by Dr. Gibſon, biſhop of London, in the treatiſe commonly known by the title of "Addiſon's Evidences of the Chriſtian Religion." In 1718 Mr. Grove publiſhed an "Eſſay towards the Demonſtration of the Soul's Immateriality," in which he relies on the argument that Dr. Clarke had urged in his debate with Mr. Collins. Hitherto he had engaged chiefly, as a tutor, in moral philoſophy, and thoſe branches of knowledge connected with it; but now, on the reſignation of Mr. Darch, one of his colleagues, he undertook the department of mathematics and natural philoſophy, which conſiderably extended his labours, and is thought to have contributed to injure his conſtitution, which was naturally weak and tender. In a very few months the ardour of his ſtudies brought on a fever, attended with extreme

extreme languor, which threatened his valuable life; the diſorder, however, did not prove fatal, and upon his recovery he compoſed "An Ode," which was afterwards printed, and has been greatly admired for the harmony of the numbers, and the exalted piety of the ſentiments. Small as his income was for the ſupport of an increaſing family, he refuſed ſeveral invitations, which would have rendered his circumſtances much eaſier, in a pecuniary point of view, but which would probably have expoſed him to ſome diſquiet, owing to the controverſy at that time agitated among the diſſenters. He loved Chriſtianity for its ſimplicity, as well as for the excellence of its doctrines, and for the rules of action which it enforces, as tending to the happineſs of man, but he was totally averſe from thoſe inventions of weak and fallible creatures, which in all caſes are highly injurious to the cauſe of ſcriptural truth. For adhering to the doctrines of the Bible, he was expoſed to the cenſures and anathemas of thoſe violent men who had ſet up, or embraced, a ſyſtem of their own, and then went to the oracles of heaven for detached paſſages in its ſupport. Many of his brethren, whoſe names ſhall not be called from the oblivion to which they have juſtly paſſed, aſſuming to themſelves the excluſive title of orthodox, repreſented Mr. Grove as indifferent to the truths of the goſpel; but their calumnies produced no change in his conduct, nor any alteration in his firm conviction, that the interpoſition of the authority and deciſions of fallible men was an improper method of determining controverſies of faith, or eſtabliſhing divine truth. He gave his reaſons for this conduct in "An Eſſay on the terms of Chriſtian Communion." In the year 1723, at the requeſt of ſeveral miniſters, he publiſhed a treatiſe on "Secret Prayer," being the ſubſtance of many ſermons on this important ſubject; in this work the wiſdom and advantage of that practice are eſtabliſhed by weighty and irrefragable arguments. In 1725, the office of divinity tutor devolved on him; the duties of which he diſcharged with the moſt exemplary zeal, and greatly to the advantage of thoſe young men who ſtudied under his direction. His next publication in 1728, conſiſted of two ſingle diſcourſes, one entitled the "Friendly Monitor," intended to point out the errors and imperfections in the conduct of ſome Chriſtians, by which they not only injure their own reputation, but bring diſcredit on the religion which they profeſs: the other was entitled, "The fear of death, as a natural paſſion, conſidered, both with reſpect to the grounds of it, and the remedies againſt it." We may alſo notice another or two of his publications, particularly "A diſcourſe concerning the nature and deſign of the Lord's Supper:" and "Wiſdom, the firſt ſpring of action in the Deity." In this latter piece, which appeared without the author's name, he endeavours to prove, that the moral perfections of God, as well as moral virtue and goodneſs in man, are founded in the unalterable relation of things, and the eſſential fitneſs and unfitneſs of actions and diſpoſitions ariſing hence. He died in February 1737, deeply regretted by all the wiſe and the good who knew him. He was in every reſpect amiable and excellent, beloved by his pupils and honoured by his contemporaries, who had an opportunity of appreciating his worth. His learning and general knowledge were various, deep, and extenſive: his judgment was ſolid, and his imagination ſtrong and lively.

GROVE, in *Gardening*, a ſort of avenue formed by trees of ſtately growth, diſpoſed in rows, in graſs grounds, gardens, and parks, on, or contiguous to, ſpacious lawns, &c. deſigned for ornament, ſhade, and ſhelter. Theſe ſorts of walks are much leſs in eſtimation at preſent than formerly, in conſequence of their very formal appearance.

In extenſive gardens or grounds they may be formed in different parts; a large one contiguous to the dwelling, where it may be conſpicuous, is often proper, both to effect ornament, and that it may afford convenient ſhade for occaſionally walking in the heat of ſummer; others may be ſtationed more remote, on the boundaries of lawns, or other open ſpaces of graſs ground, and near garden buildings, ſuch as ſummer-houſes, temples, and other ſtructures, as whereever they are ſituated they always exhibit an air of grandeur, and are great ornaments to ſpacious gardens. Such gardens are indeed incomplete without one or more of ſuch plantations.

The trees, in forming groves, are uſually diſpoſed in ſeveral ſtraight rows, and at ſuch diſtances that their branches may ſo far approach each other, as to afford a moderate ſhade from the ſummer's ſun, yet ſo diſtant that each tree may have full ſcope to ſpread its branches all around, ſo as to exhibit their ſtraight trunks and ſpreading heads diſtinct, according to their natural growth, and that a due proportion of air and light may be admitted to promote the growth of the graſs between and under them, ſo as to form a cloſe, firm ſward, and conſtant verdure; they are alſo ſometimes formed with the trees placed irregularly, and the ſpaces between planted with various ſorts of ſhrubs to form underwood, and with ſerpentine gravel walks variouſly winding through the whole. The trees and ſhrubs that are moſt proper for this uſe are thoſe of the occiduous and ever-green tall growing kinds, which form handſome heads.

They are diſtinguiſhed into two ſorts, *open groves*, and *cloſe groves*.

For the firſt ſort, the handſomeſt growing ornamental foreſt trees, with the moſt ſpreading heads, ſhould be choſen, and diſpoſed in ranges from fifteen to twenty or thirty feet wide, and the ſame diſtance between the trees in each row, that each tree may have full ſcope to form a ſpreading head, and ſo as to admit of the growth of graſs under them without injury. Where a ſhady grove is required to be formed as ſoon as poſſible, it may be planted contiguous, but diſtinct from the above, arranging the rows only at ten or fifteen feet diſtance, by which it will afford ſhade ſeveral years ſooner than the other; and as exhibiting a darker and more gloomy ſhade, will afford the greater variety in contraſt with it. Open groves, chiefly for ſhade, may alſo be formed by diſpoſing all the trees irregularly, that they may produce an imitation of a natural grove, and ſooner afford a perfect ſhade and gloomineſs, which they effect conſiderably ſooner than in ſtraight rows.

The latter ſort of groves are formed of large trees, ſome planted in ſtraight lines, others irregularly diſpoſed, having the ground between them filled with various under ſhrubs, and gravel or ſand-walks continued through them in winding or ſerpentine turns; and are ſometimes continued round the outer boundaries of pleaſure grounds, parks, &c. as ornamental plantations, and to afford ſhady and private walking, as well as ſhelter from the inclemency of cold cutting winds. The various ſhrubs forming the underwood have a delightful effect in the whole of the walks quite round. In forming groves in general, it ſometimes happens, when gardens or pleaſure-grounds are laid out, that large old trees are found growing in a proper ſituation to conſtitute a grove, which, if they do not too greatly approach to the habitation, or obſtruct any principal proſpect or diſtant view, ſhould be preſerved with care; and although they ſhould ſtand ever ſo irregularly or cloſe, they may be ſomewhat regulated by grubbing up the moſt irregular and ill formed, or thinning out ſome, where they form too cloſe a thicket for the deſign, either for an open or cloſe grove. By proper care in this

this reſpect a grove may often be formed in a very ſhort ſpace of time, and with but very little trouble.

GROVES have been in all ages held in great veneration. The *proſeuchæ*, and high-places of the Jews, whither they reſorted for the purpoſes of devotion, were probably ſituated in groves. (See Joſhua, xxiv. 26.) The proſeuchæ in Alexandria, mentioned by Philo, had groves about them, becauſe he complains that the Alexandrians, in á tumult againſt the Jews, cut down the trees of their proſeuchæ: that at Rome, in Egeria's grove, was of the ſame ſort. The veneration which the ancient druids had for groves is well known. See DRUIDS.

The ancient Romans had a ſort of groves near ſeveral of their temples, which were conſecrated to ſome god, and called *luci*, by Antiphraſis, *á non lucendo*, as being ſhady and dark: theſe groves are expreſsly enjoined by the twelve tables as a part of the public religion. The inſtitution of conſecrated groves is ſuppoſed to be as ancient as the patriarchal ages; for we are informed, that "Abraham planted a grove in Beerſheba, and called there on the name of the Lord." (Gen. xxi. 33.) But it cannot be juſtly inferred from this paſſage, that the patriarch planted the grove for any religious purpoſe. However this be, the inſtitution of conſecrated groves is ſo ancient, that ſome have thought it to be antecedent to that of temples and altars. At firſt theſe groves had neither temples nor altars; they were ſimple retreats to which the profane had no acceſs; meaning by profane thoſe who were not devoted to the ſervice of the gods. Afterwards, they built chapels and temples in them; and they alſo took care, whenever it was practicable, to encloſe them with walls, hedges, or ditches; and theſe groves were not only conſecrated to the gods, in honour of whom the temples in the centres of them had been built, but they were themſelves a place of ſanctuary for criminals, who fled thither for refuge. As the idolatrous nations worſhipped in groves, Moſes, under divine inſtruction, with a view of guarding the Iſraelites from idolatry, expreſsly forbade "the planting a grove of trees near his altar." (Deut. xvi. 21.) Nor would he ſuffer them to offer their ſacrifices on the tops of hills and mountains as the heathens did; but ordered that they ſhould be brought to one altar, in the place which God appointed. (Deut. xii. 13, 14.) And as for the groves which the Canaanites had planted, and the idols and altars which they had erected on the tops of high mountains and hills for the worſhip of their gods, the Iſraelites are commanded utterly to deſtroy them. (Deut. xii. 2, 3.) The groves and high places ſeem to have been the ſame places, or groves planted on the tops of hills, probably round an open area, in which the idolatrous worſhip was performed. See Hoſea, iv. 13.

Various conjectures have been offered in order to account for the reaſon and origin of planting ſacred groves. Some have imagined this was done in order to render the ſervice more agreeable to the worſhippers by the pleaſantneſs of the ſhade, whilſt others ſuppoſe that the gods were thus allured to be preſent. This ſeems, according to Virgil, to have been the reaſon of Dido's building the temple of Juno in a delightful grove:

"Lucus in urbe fuit mediâ, lætiſſimus umbrâ:
Hic templum Junoni ingens Sidonia Dido
Condebat." Æn. l. i v. 445.

The one or other of theſe reaſons ſeems to be intimated in the paſſage of Hoſea above cited. Others conceive their worſhip was performed in the midſt of groves, becauſe the gloom of ſuch a place is apt to fill the mind with a religious awe (ſee Seneca, Ep. xli. And Virgil's Æn. viii v. 347 et ſeq.); or elſe, becauſe ſuch dark concealed ſituations ſuited the lewd myſteries of their idolatrous worſhip. In proof of the lewdneſs and obſcenity of many of the religious rites of the heathens, we may refer to Herodot. Euterpe, v. 64. et Clio § 199. Diod. Sic. l. iv. init. Valer. Max. l. ii. c. 6. § 15. Juv. Sat. ix. v. 24. and to what Euſebius ſays of a grove on mount Libanus, dedicated to Venus, in his "Life of Conſtantine," l. iii. c. 55. See alſo 1 Kings, xiv. 23, 24.

There remains to be mentioned another conjecture which ſeems as probable as any; *viz.* that this practice began with the worſhip of dæmons or departed ſouls. It was an ancient cuſtom to bury the dead under trees, or in woods. (See Gen. xxxv. 8. 1 Sam. xxxi. 13.) An imagination prevailed among the heathens, that the ſouls of the deceaſed hover about their groves, or at leaſt delight to viſit their dead bodies; and hence the idolaters, who paid divine honours to the ſouls of their departed heroes, were led to erect images and altars for their worſhip in the ſame groves where they were buried (ſee Plato de Republ. l. v.); and from thence it became afterwards a cuſtom to plant groves, and build temples near the tombs of departed heroes (2 Kings, xxiii. 15, 16. Arrian de Exped. Alex. l. vi.); and to ſurround their temples and altars with groves and trees. From this cuſtom of planting trees near temples, the poets, as Strabo informs us (Geog. l. ix.) ſtyled all their temples groves, even thoſe which had no plantations around them. The ſacred groves being conſtantly furniſhed with the images of the heroes or gods that were worſhipped in them, a grove and an idol came to be uſed as convertible terms. (2 Kings, xxiii. 6.) Theſe ſacred groves were uſually planted on the tops of hills or mountains, from which circumſtance they were called in Scripture בָּמוֹת, (bamoth) or "high places." Perhaps, ſuch an exalted ſituation was choſen by idolaters in reſpect to their chief god, the ſun, whom they worſhipped, together with their inferior deities, on the tops of hills and mountains, that they might approach as near to him as they could. To this purpoſe, Tacitus (Annal. l. xiii. § 57.) ſpeaks of ſome places which were thought "maximè cœlo propinquare, preceſque mortalium á Deo nuſquam propius audiri." It is no improbable conjecture concerning the Egyptian pyramids, that they were intended as altars to the ſun, as well as for ſepulchral monuments, like thoſe ancient groves. Accordingly they are all flat at the top, to ſerve the purpoſes of an altar. It is ſaid, that altars to the ſun, of the ſame form, though not ſo large as the pyramids, were found among the American idolaters. (See Young's Hiſtorical Diſſertation on idolatrous Corruptions in Religion, vol. i. p. 222—223.) Another reaſon for planting the ſacred groves on the tops of hills and mountains, was the benefit of retirement from noiſe and interruption in acts of worſhip: "Lucos et ipſa ſilentia adoramus," ſays Pliny (Nat. Hiſt. l. xii. c. 1.). It was probably on this account that the worſhippers of the true God had alſo their proſeuchæ, or places of retirement for worſhip, generally on hills or high places. Thus we read (Matt. xiv. 23.) that Chriſt "went up into a mountain apart to pray." At his transfiguration he retired with three of his "diſciples to the top of a high mountain apart." (Matt. xvii. 1.) Hence it appears, that we have no reaſon for concluding that the high places mentioned in the Old Teſtament, where holy men and worſhippers of the true God paid their devotion, were the ſacred groves of the idolaters; but that they were rather Jewiſh proſeuchæ, or ſynagogues. (See 1 Sam. ix. 12—14. x. 5—13. 1 Kings, iii 4, 5. Jennings's Jewiſh Ant. vol. ii.) See PROSEUCHÆ and SYNAGOGUE.

GROVE-

GROVE-*wood*, in *Mining*, ſignifies very ſtout underwood, or the thinnings of plantations, of which the puncheons, ſtemples, ſtauncheons, or poſts are made, which are uſed to ſupport the roof or ſhafts of mines.

GROUND, in *Agriculture*, a term commonly applied to land, whatever the nature of it may be. It is alſo occaſionally uſed to ſignify a graſs-land incloſure which lies out of the way of floods; and ſometimes in contradiſtinction to meadow-land. See SOIL.

GROUND, in *Mining*, ſignifies the ſpace or field occupied by a mine; thus, mining ground ſignifies a place where there are mineral veins or ſeams.

GROUND *Angling*. See ANGLING.

GROUND *Arms*, in *Military Language*, a word of command, on which the ſoldiers lay down their arms upon the ground: but this term is exploded, and ſoldiers are now ordered "to pile their arms."

GROUND, *To Take*. A battalion or company is ſaid to take ground, when it extends in any given direction. A ſimilar expreſſion is uſed in duelling, *e. g.* they took their ground at eight or ten paces from one another.

GROUND-*bailiff of a Mine*, or under-ground agent, is the foreman, overlooker, or perſon having the charge of the works in a mine; in ſome places ſuch perſon is called the overman.

GROUND *Baſe*, a term in *Muſic*, for a few bars, or notes, repeated in the baſe as a foundation to different trebles: ſuch were the ſounds upon which the *Chaconne* was uſually built, during the 17th and part of the 18th century. See STRADELLA and PURCELL.

GROUND *Battable*. See BATTABLE.

GROUND, among *Bowlers*. See BOWLING.

GROUND *Breaking*. See BREAKING.

GROUND, *Commanding*. See COMMANDING.

GROUND-*drove*, *in a Mine*, is ſaid of ſuch parts as have been worked, or excavated for the ore or minerals.

GROUND-*end of a Mine*, ſignifies the foreſield or foremoſt place of working, in the whole or foot ground.

GROUND, in *Etching*, denotes a varniſh ſmeared over the ſurface of the metal to be etched, to prevent the aqua-fortis from eating, or having effect, except in places where this ground is cut through, or pared off, with the points of needles. For the method of preparing it, ſee ETCHING.

GROUND *Ivy*, in *Botany*, &c. See GLECHOMA.

GROUND *levelling Machine*, in *Agriculture*, the name of an implement contrived for the purpoſe of reducing land into a level and even ſtate. See MACHINE.

GROUND *Line*, in *Perſpective*, is the interſection of the picture with the ground plane.

GROUND, in the *Manege*. See TERRAIN.

GROUND, *Manuring*. See MANURING.

GROUND *Niche*. See NICHE.

GROUND *Nut*. See EARTH-*nut*.

GROUND, *Oazy*. See OAZY.

GROUND *Officer*, in *Agriculture*, the name of a perſon who has the managing and overlooking of land.

GROUND *Paſture*. See PASTURE.

GROUND *Pine*, in *Botany* and *Medicine*, &c. See GERMANDER.

GROUND *Plane*, in *Perſpective*, is the ſituation of the original plane in the ſuppoſed level of our horizon; it only differs from horizontal plane in this, that the horizontal plane is any plane parallel to our horizon, whether above or below it; whereas ground plane is ſuppoſed to be at one diſtance only from the centre of the earth: and this diſtance, the ſuppoſed level on which the object to be drawn, is placed on the earth's ſurface.

The ground plane is ſtill more confined with regard to ſituation than the original plane, which may be either parallel or inclined in all poſitions to the ground plane; we ſhall therefore, in reſpect of the original object, the interſection of the picture, the directing, and other lines ſituated in the original plane, refer our readers for further information to *Original* PLANE, and to the article PERSPECTIVE.

GROUND *Plate*, or *Ground-ſill*, the loweſt horizontal timbers on which the exterior walls of a building are erected. It chiefly occurs in timber buildings, or buildings, the outſide walls of which are of brick, ſurrounded by timber framings.

GROUND *Plot*, a piece of ground ſelected for building upon. For dwellings its chief properties are, a healthy ſituation, a convenient ſupply of water and of all other neceſſaries of life, and an agreeable ſituation: if for trade or manufacture, its communication muſt be ready for receiving the materials, and exporting the articles of manufacture.

GROUND *of a ſhield*, or *eſcutcheon*, in *Heraldry*, is properly called the *field*.

GROUND, in *Painting*, is the ſurface upon which the figures, and other objects, are raiſed or repreſented. See PAINTING.

Ground is properly underſtood of ſuch parts of the piece as have nothing painted on them, but retain the original colour, upon which the other colours are applied, to make the repreſentations.

A drapery, piece of building, or the like, are ſaid to ſerve as a ground to a figure, when the figure is painted on the drapery or building.

In the like ſenſe, we alſo ſay, the ground of a piece of tapeſtry, of an embroidery, of a medal, coin, &c.

GROUND *Steward*, a perſon who has the direction of land.

GROUND *Tackle*, a *Sea Term*, denoting a ſhip's anchor, cables, &c. with what is neceſſary to make her ride ſafe at anchor in a proper *ground*.

GROUND *Timbers*, in a *Ship*, are thoſe whoſe timbers lie on her keel, and are faſtened to it with bolts through the keelſon. They are ſo called, becauſe the ſhip lies at reſt upon them when ſhe is aground.

GROUND-*work*, in *Building*. See FOUNDATION.

GROUND-*worm*. See WORM, and EARTH-*worm*.

GROUNDAGE, a cuſtom or tribute, paid for the ſtanding of a ſhip in a port. Blount.

GROUNDING *of a Ship*, is the bringing her on *ground*, to be trimmed, made clean, or to have ſome leak ſtopped in her.

The term is alſo applied to a ſhip's running aground accidentally, when under ſail, or driving in a tempeſt.

GROUNDLING, an Engliſh name for a ſmall ſpecies of the *cobitis*; which ſee.

GROUNDSEL, in *Botany*. See SENECIO.

GROUNDSEL, *African*. See *Foreign* COLTSFOOT.

GROUNDSEL, *German*. See STELLERA.

GROUNDSEL *Tree*, in *Gardening*, the common name of a plant. See BACCHARIS.

GROUP, in *Painting* and *Sculpture*, is a combination of objects in one maſs, to prevent diſtraction or confuſion in a work of art. The word is French, *grouppe*, from the Italian *groppo*, a knot or cluſter.

A group has ſomewhat in it of the nature of a ſymphony, or concert of voices: as, in the one, the voices muſt ſuſtain each other, in order to fill the ear with an agreeable harmony from the whole; whence, if any part were to ceaſe, ſomething would neceſſarily be miſſed; ſo in the other, if the

parts, or figures, be not well balanced, ſomething will be found diſagreeable.

GROUP, in *Muſic*, is one of the kinds of diminutions of long notes, which in the writing forms a ſort of group, or cluſter.

The group uſually conſiſts of four crotchets, quavers, or ſemiquavers, tied together at the diſcretion of the compoſer.

GROUPADES is corruptly uſed in the *Manege* for croupades.

GROUPED COLUMNS, or *Pilaſters*, are thoſe of which more than two are conjoined; precedents of this deſcription are not to be found among the ruins of the ancients, nor are they conformable to the ſtrict rules of architecture, and though ſome few examples exiſt in modern buildings, they are not very numerous.

GROUPING, in *Painting* and *Sculpture*, is in fact the ſame as the art of compoſing, or combining the objects of a picture, or piece of ſculpture. So much has been ſaid upon this ſubject under the article COMPOSITION *in the Arts of Deſign*, that little can here beneficially be added. We ſhall only obſerve, that in a work of great extent in painting, there ſhould not only be found well compoſed groups, but alſo groups of groups. That is, the larger maſſes ſhould be diviſible into ſmaller ones, and all the groups ſhould unite to form the whole; and the parts ſhould alſo be ſo connected in their approximation to each other, that the eye may be readily conveyed from each to each, and unite them agreeably in one view.

The nature of the ſubject propoſed to be treated is the only guide for the formation of groups; which may conſiſt of two or more figures, according to what is required for the illuſtration of it.

GROUSE, or GROUS, in *Ornithology*, is a general name comprehending ſeveral ſpecies of birds, which Linnæus has claſſed under the genus of *Tetrao*; which ſee.

The wood-grous, called alſo the *urogallus major*, and cock of the mountain, or wood, is the *tetrao urogallus* of Linnæus. The male of this ſpecies ſometimes weighs fourteen pounds: its bill is of a pale yellow colour; the noſtrils are covered with duſky feathers; the head, neck, and back, are elegantly marked with ſlender lines of grey and black, running tranſverſely. The feathers on the hind part of the head are long, and beneath the throat is a large tuft of long feathers. The upper part of the breaſt is of a rich gloſſy green; the reſt of the breaſt and belly black, mixed with ſome white feathers; the ſides are marked like the neck; the coverts of the wings are croſſed with undulated lines of black and reddiſh brown: the exterior webs of the greater quill-feathers are black, and at the ſetting on of the wings in both ſexes is a white ſpot; the tail conſiſts of eighteen black feathers, marked on each ſide with a few white ſpots; the legs are covered with brown feathers, and the edges of the toes pectinated. The bill of the female is duſky; its throat red; its head, neck, and back, marked with tranſverſe bars of red and black; the breaſt has ſome white ſpots on it, and the lower part is of a plain orange colour; the belly is barred with pale orange and black; the tips of the feathers are white; the feathers of the back and ſcapulars are black, the edges being mottled with black and pale reddiſh brown; the ſcapulars are tipt with white; the tail is of a deep ruſt-colour, barred with black, tipt with white, and conſiſts of ſixteen feathers. The female is conſiderably leſs than the male. Theſe differences between the male and female led ſome writers to make the male and female of this ſpecies two different ſpecies; and Geſner has diſtinguiſhed them in this manner, calling the female the *grygallus minor*, and the male the *grygallus major*. This ſpecies is found in no other part of Great Britain except the Highlands of Scotland, where it is known by the name of *capercalzie*, and in the old law books *caperkally*, the horſe of the woods. It inhabits woods and mountainous countries, and feeds on the tops of pines and birch-trees, and the berries of juniper. Theſe birds are common to Scandinavia, Germany, France, and ſeveral parts of the Alps; and are generally reckoned well-taſted food.

Another ſpecies of the grouſe is the black game, heath-cock, or black cock, being the *tetrao tetrix* of Linnæus; the male, which is called the *urogallus minor*, has a duſky bill; the plumage of the whole body is black, gloſſed over the neck and rump with a ſhining blue; the coverts of the wings are of a duſky brown, the inner coverts white; the thighs and legs are covered with dark brown feathers, and on the former are ſome white ſpots; the tail conſiſts of ſixteen black feathers, and is much forked; the feathers under the tail are of a pure white. The weight of an old black cock is about four pounds. The female weighs about two pounds; the head and neck are marked with alternate bars of dull red and black; the breaſt with duſky black and white; the back, coverts of the wings, and tail, are of the ſame colours with the neck; the inner coverts of the wings are white; and in both ſexes form a white ſpot on the ſhoulder; the tail conſiſts of eighteen feathers, variegated with red and black, and ſlightly forked. This ſpecies of birds frequent the ſame ſituations with the former: they feed on bilberries and other mountain fruits, and in winter on the tops of the heath: in ſummer they often deſcend from the hills to feed on corn. They never pair, but in ſpring the male gets on an eminence, crows, and claps his wings; on which ſignal, all the females within hearing reſort to him. The hen lays from ſix to eight eggs, which are hatched late in the ſummer. The young males, which quit their mother in the beginning of winter, keep together in flocks of ſeven or eight till ſpring, during which time they inhabit the woods. There is another variety of the black cock, which differs from the common ſort in being ſpotted on the neck, breaſt, wings, and thighs, with red: ſuch is alſo the *tetrao hybridus* of Linnæus. Pennant.

Another ſpecies of grouſe is the red-game, moor-cock, or gor-cock, a variety of the TETRAO *lagopus*. A fourth ſpecies is the white game, TETRAO *lagopus* of Linnæus, or *ptarmigan*. For other ſpecies that paſs under the denomination of grouſe, ſee TETRAO.

GROUT, in *Engineery*, is a thin or ſemi-liquid mortar, of quick lime, with a portion of fine ſand, which is prepared and poured into the internal joints of the walls of locks, bridges, &c. and over the tops of arches on canals, &c. for cementing the whole more firmly together; the proceſs is called *grouting*.

GROUT, or *Growt*, in *Building*, is a very thin coarſe mortar; when it is mixed with bullock's hair, it is called *hair grout*. See *Extinguiſhing of* FIRE. Alſo *Calcareous* CEMENT.

GROWA, in *Geography*, a town of Africa, on the Slave coaſt. N. lat. 4° 25'. W. long. 7° 20'.

GROWAN, in *Natural Hiſtory*, a word uſed by the miners in Cornwall to expreſs a ſort of coarſe and gritty ſtone, which they are uſually obliged to dig through before they come to the veins of ore. This is uſually grey or whitiſh, but ſometimes it is of various colours, often yellowiſh, and ſometimes ſpotted with iron colour, and an inky black; and often its texture is ſo looſe and ſpongy, that there are holes in it of the ſize proper to receive a pea or a horſe-bean; theſe are ſometimes empty, but more uſually they

they are filled up either with chalk or with ſpar. Beſide the ſtrata of this ſtone that lie over the ore, there is alſo a large quantity of it placed by its ſide. They have this, and two other ſorts of ſtone, lying in the way to the tin ore in Cornwall. The firſt of the others they call *moor-ſtone*, a very uncertain name, as it is alſo given by ſome to the common white granite of that country; but the miners only mean by it a looſe ſort of free ſtone, ſomewhat ſofter than that uſually employed in building. The other ſtone is called *killos*: this is a grey ſtone of the ſlate kind, eaſily ſplitting into thin plates, and is very full of talcy flakes: this *killos* is, however, a very indeterminate name, as well as the other, for the ſame people ſometimes uſe it alſo to ſignify a white earth common among them; this laſt, however, they ſometimes diſtinguiſhed by the epithet *white*. The word growan ſeems the only name they have kept to any determinate ſignification, for they never expreſs by this word any other ſubſtance than the ſtone above deſcribed.

GROWERS, in *Agriculture*, a term provincially applied to farmers.

GROWING, in *Sea Language*, denotes the direction of the cable from the ſhip toward the anchors: thus, the cable *grows* on the ſtarboard bow, when it ſtretches out forward on the ſtarboard or right ſide.

GROWME, in our *Old Writers*, an engine to ſtretch woollen cloth after it is woven; it is mentioned in the ſtatute 43 Edw. III. cap. 10.

GROWTH HALFPENNY, a rate ſo called, and paid in ſome places for the tithe of every fat ox or other unfruitful cattle.

GRUAPET, in *Geography*, a town of Hindooſtan, in the Carnatic; 15 miles N.N.W. of Bomrauzapollam.

GRUARII, in our *Old Writers*, the principal officers of the foreſt in general. The word comes from the old French *gruyer*, which ſignifies the ſame.

GRUB, the Engliſh name of the hexapode worms or maggots hatched from the eggs of beetles. (See SCARABEUS.) Grubs are an excellent bait for many kinds of fiſh. In angling for the grayling, the aſh-grub is to be preferred to all others. This is plump, milk white, but round from head to tail, and has a red head. There is alſo another grub, which is very common, and is longer and ſlenderer than the aſh-grub; it is yellower and tougher, and is known by having a red head, and two rows of legs all along the belly. The trout and grayling uſually frequent the ſame places, and it is not uncommon to take the trout, while fiſhing for the other. Theſe grubs are to be kept in bran, in which they will grow tougher than they were at firſt; but the aſh-grub is always ſo tender, that it is difficult to make a good bait of it. The beſt method is to wrap it in a piece of ſtiff hair with the arming, leaving it ſtanding out about a ſtraw's breadth at the head of the hook, ſo as to keep the grub from totally ſlipping off when baited: the horſe-hair that the hook is faſtened to ſhould be as white as poſſible, that it may reſemble the colour of the bait, and not be ſuſpected.

GRUB, in *Agriculture*, the name of a large maggot produced from the *ova* of a certain ſpecies of inſect; and which is of a large ſize, and frequently does great injury to grain crops, by undermining and feeding upon the roots of the plants. It is a ſort of beetle, which by ſome is denominated the rook-worm, in conſequence of the rooks being extremely fond of it. Such ground as has been newly brought into cultivation is in common the moſt ſubject to this inſect. It is probable that the beſt mode of deſtroying grubs, is by good and frequent ploughing, rolling, and the uſe of lime in pretty large proportions in its more cauſtic ſtate, which generally clears the land for ſeveral years, however it may be infeſted with this ſort of grub.

In the Farmer's Magazine it is ſtated, that there is a ſort of grubs "met with in wet ſituations every year, in greater or ſmaller numbers, in proportion to the heat or cold of the preceding ſeaſon. While the inſect remains in the egg ſtate, no inclemency of weather can hurt it; a fact, of which laſt year, it is ſaid, affords a convincing proof; for, notwithſtanding the ſeverity of the winter 1799, and the coldneſs and inclemency of the following ſpring, immenſe numbers were produced, which, by their ravages upon the oat crop, contributed not a little to increaſe the public diſtreſs. While in the grub ſtate, it is likewiſe invulnerable; and the fly produced is equally hardy. The only ſtage of its exiſtence, in which it appears ſuſceptible of injury, is, it is ſuppoſed, in paſſing from the grub to the aurelia ſtate, when rains and cold weather are fatal to it; and as, in ordinary years, that change takes place about the end of May, or beginning of June, a period at which rain commonly falls in conſiderable quantity, nearly the whole race periſh every year, except ſuch as have taken up their reſidence in the ſoft dry mole hills that are met with in meadows, or in the ſides of ditches; for, upon all the arable lands, it is believed, very few remain to propagate the ſpecies, unleſs in ſeaſons when the weather is uncommonly dry during the whole of the period they remain in the aurelia ſtate, as was the caſe in 1798. A part of May, and the whole of June, paſſed over with very little rain; in that way, a great proportion of the eggs, depoſited in the arable lands, ſurvived, and became grubs."

But "in tracing the hiſtory of an inſect ſo very deſtructive, and which, were every ſeaſon alike favourable to its production, would ſoon render the world a deſart, we are ſtruck with the circumſtance of its being ſo readily deſtroyed by moiſture, at the time when the rains, to it ſo fatal, are ſo highly neceſſary and uſeful to the crops."

However, "this grub is not the only one by which the crops are injured. There are ſeveral others, pretty numerous, and equally deſtructive, produced in dry ſoils, and in all ſeaſons: theſe, like that already noticed, reſiſt every injury of the weather throughout the year, and in every ſtage of their exiſtence, except when they are in the aurelia ſtate, when cold and moiſt weather kills them. The whole of the grubs bred upon dry lands are of the moth tribe. One of the moſt deſtructive of theſe comes into exiſtence, if the autumn has been very warm, about the end of October, and continues to increaſe in ſize, as long as any tolerable degree of vegetation is going on; after which, owing evidently to the want of food, it remains ſtationary till the following ſpring; at an early period of which, its depredations are obſerved. About the end of February it begins to grow, and continues increaſing in ſize till the beginning of May, when it is upwards of an inch in length, and about one-third of an inch in circumference. It is then exceedingly deſtructive, and eats through the roots of the ſtrongeſt ſtalks of grain in a very ſhort time." The writer "this year took one of them, and put it into the earth, which conſiſted of ſoft black loam, at the root of a plant of oats that had ſent out thirty-ſeven offsets, and had been well earthed up. The grub was put in about mid-day, and well covered up. The plant was examined next day about the ſame hour; when the leaves were found hanging down, ſeemingly in a dying ſtate. Upon looking at the root, he found not only the main ſtem, but the whole of the offsets, ſo much injured, that there appeared little hopes of their recovery. Accordingly, in a few days thereafter, they were all dead." He ſtates, in addition, that, "in ſeaſons when they are numerous,

rous, the miſchief they occaſion is certainly very great: fortunately, however, nearly the whole race periſh every year; and the ſtock is kept up from the eggs depoſited in the ſides of ditches, in plantations, and amongſt coarſe-fogged herbage, which preſerve the aurelia from being injured by moiſture. In deſcribing an inſect ſo very deſtructive, it would afford him great ſatisfaction to be able to point out a remedy for the evil; of that, however, he confeſſes himſelf in a great meaſure ignorant. Lime, in the act of ſlacking, is certainly fatal, not only to the grub, but to inſects of every deſcription, which come within the reach of its influence. But, though it is thus baneful in a hot active ſtate (a circumſtance that well deſerves the attention of all farmers), he does not find it equally ſo, after it has re-abſorbed a proportion of carbonic acid, ſufficient to reduce it to a powder. It is certain that grubs are leſs numerous in fields that have been recently limed, than in lands of the ſame quality, to which no lime has been applied. Still, however, they live in ſuch ſoils, and propagate their kind; and he is inclined to think, that after the lime has completely ſaturated itſelf with fixed air, and got into a mild ſtate, the vermin will thrive equally well in ſuch fields, as if no lime had been applied. One mode of prevention certainly is in the power of every farmer, namely, that of keeping the tops of ditches and hedge ſides clean and free from that rough noxious herbage with which they are for the moſt part covered, and which, along with their ſerving as a nurſery for grubs, and many other kinds of vermin, are a fruitful ſource of miſchief, from the numerous weeds yearly produced upon them, the ſeeds of which are wafted into the adjoining fields by the winds, and, in ſpite of fallowing, and every other attention that can be paid, furniſh a freſh ſtock annually, by which the ſoil is conſtantly kept in a dirty ſtate, and much labour and expence incurred, that might, with a ſmall degree of attention, be avoided."

Notwithſtanding theſe judicious obſervations, there ſtill remains much to be done, in order to perfect our knowledge of the nature and modes of deſtroying theſe very deſtructive and miſchievous grubs.

GRUB, in *Rural Economy*, a term ſignifying to dig up by the roots, as in the caſe of trees, &c.

Grub *of the box*, or *box-puceron*, in *Natural Hiſtory*, a name given to a ſort of inſect approaching to the nature of the puceron of the elder and other trees, but differing from that animal in ſome eſſential characters, and being more properly of the ſame genus with the fig-inſect or falſe puceron. Reaumur's Hiſt. Inſ. vol. vi. p. 100. See Fig-*inſect*.

Theſe inſects change their ſkin ſeveral times, in the manner of the pucerons, and they change their colour at the ſame time. They are at firſt reddiſh, but they are then extremely ſmall; after this they throw off a ſkin and become yellowiſh; after this they are of a deeper yellow, ſpotted with black; and finally, when at their full growth, they are greeniſh, and have black antennæ. The exuviæ which theſe creatures leave behind them, have often a grain of the excrement remaining fixed to them.

Mr. Reaumur, who took great pains to know the hiſtory of theſe minute animals, found that they finally became flies of a peculiar kind, reſembling thoſe of the fig-inſect; they hopped in the manner of graſshoppers, but only a little way at a time, and he was able to diſcover the parts peculiar to the male and female ſex, in the different individuals, but never could find any eggs or embryo-animals in the latter.

Grub, *Vine*, in the *Hiſtory of Inſects*. See Vine.

Grub-*felling*, in *Rural Economy*, a term applied to the method of felling trees by means of grubbing them up by the roots.

GRUBBIA, in *Botany*, ſo named by Bergius, Pl. Cap. 90, in compliment to his friend Michael Grubb, a director of the Swediſh Eaſt India company, and member of the Academy of Stockholm, who furniſhed him with his whole collection of Cape plants. Juſſieu conſiders it as very nearly, if not entirely, the ſame genus with *Empetrum*. However that may be, it is certainly the very ſame plant as the *Ophira ſtricta* of Linnæus, to which we refer the reader.

GRUBBING, in *Agriculture*, the work of extirpating and clearing land from trees, roots, ſtumps, ſtones, buſhes, ſhrubs, &c. It has long ſince been noticed by Worlidge, that the beſt and cheapeſt mode of grubbing up thorns, broom, gorſe, &c., is adviſed by Platt, and is that of wrenching them up by means of a ſtrong lever all at once. The tool recommended for this purpoſe has much the reſemblance of a three-pronged ſtrong fork, but conſiderably larger and ſtronger in every way, ſo as to ſuit the ſtrength of the objects it has to contend with. The handle conſtitutes the lever. In working, it is placed about half a foot from the root of the trees, &c., which it is to raiſe, and driven to a good depth by means of a good hedging-beetle; then the root is raiſed by placing ſomething as a fulcrum, and forcing down the handle by fixing a rope or other ſimilar ſubſtance to the end of it. In this way the root or buſh is at once wrenched up. See *Clearing of* Land.

Grubbing *a cock*, a term uſed by cock-fighters, for the cutting off the feathers under the wings. It is a thing not allowed by cockpit-law, nor to cut off his feathers in any handling place.

Grubbing *Mattock*, the name of a tool of the pick kind, with two broad cutting ends, formed in different directions.

GRUBE, Herman, in *Biography*, was born at Lubec, in October, 1637; his father exerciſed the trade of a ſhoemaker. He qualified himſelf to attend ſome young gentlemen in the quality of tutor, in their ſtudies at Lubec and Kiel, and applied himſelf zealouſly to medicine, while he ſuperintended the progreſs of his pupils. He was made maſter of arts at Jena in 1663, and being afterwards at Leyden, the profeſſors, in conſideration of his inability to pay the expences of his promotion, and his acknowledged merit, conferred the degree of M. D. upon him gratuitouſly. After this honourable advancement he ſettled in Denmark, where he died in February, 1698. He left the following works: 1. "Analyſis mali citrei compendioſa," Copenhagen, 1668.—2. "Commentarius de modo ſimplicium Medicamentorum Facultates cognoſcendi," 1669.—3. "De arcanis Medicorum non arcanis commentatio," 1673.—4. "De tranſplantatione Morborum analyſis nova," Amſt. 1674.—5. "De ictu Tarantulæ, et vi Muſices in ejus curatione," Frankfort, 1679. Eloy. Dict.

Grube, in *Geography*, a town of the duchy of Holſtein; 12 miles N. N. E. of Ciſmar.

GRUBEN, a town of Sileſia, in the principality of Neiſſe; 8 miles S. E. of Grockau.

GRUBENHAGEN, a town and caſtle of Weſtphalia, ſituated on a mountain in a principality of the ſame name; 6 miles N. W. of Nordheim.

Grubenhagen, a principality of Weſtphalia, formerly belonging to the electorate of Hanover, containing ſome fertile land, but for the moſt part mountainous and woody. The inhabitants raiſe a great number of horned cattle and ſheep, cultivate flax, and carry on ſome linen manufactures, but their principal wealth conſiſts in wood; the foreſts, particularly that of Hartz, abounding in oak, beech, firs, elms, &c. Here are alſo quarries of ſlate, limeſtone, marble, alabaſter, and various ſorts of jaſper; ſalt-ſprings, mines of

of ſulphur, calamine, and ſome mines of gold; alſo rich mines of ſilver, copper, iron, and lead. The rivers of this country are the Leine, the Ruhme, the Soſe, and the Ocker. The inhabitants are Lutherans. The capital is Eimbeck.

GRUDACK, a town of Auſtrian Poland, in Galicia; 28 miles S. W. of Lemberg.

GRUDECK, a town of Poland, in the palatinate of Podolia; 32 miles W. of Kaminiec.—Alſo, a town of Poland, in the palatinate of Braclaw; 28 miles E. of Braclaw.—Alſo, a town of Poland, in the palatinate of Kiev; 50 miles W.N.W. of Bialacerkiev.

GRUDGINGS, in *Agriculture*, a term applied provincially to pollard or bran of a fine kind.

GRUDOLO, La, in *Geography*, a town of Naples, in Abruzzo Citra; 14 miles S. E. of Salmona.

GRUDZEA, a town of Pruſſia, in the palatinate of Culm, on the Viſtula; 12 miles N. of Culm.

GRUES, in *Ornithology*. See Grus.

GRUINA, the *crane-fly*, a name given by ſome authors to the *tipula*, or father-long-legs, from its legs being like thoſe of a crane. See Crane-*fly*.

GRUINALES, in *Botany*, from *Grus* or *Gruis*, a Crane, a natural order of plants, the 14th of Linnæus's *Fragmenta*, which includes *Geranium* and its allies, along with *Linum*, *Aldrovanda*, *Droſera*, and ſeveral genera related to it, *Guaicum*, *Quaſſia*, *Zygophyllum*, *Fagonia*, *Tribulus*, and *Averrhoa*, certainly all together an unnatural aſſemblage, notwithſtanding the ingenious train of reaſoning offered by Linnæus in his *Prælectiones*, p. 320—325, for bringing them together. It may be doubted nevertheleſs whether Juſſieu has been more fortunate in the places he has choſen, for *Droſera* and *Averrhoa* at leaſt; though in founding his order of *Rutaceæ*, an order but imperfectly known to himſelf, he has led the way to further improvement reſpecting moſt of the other genera.

GRULICH, in *Geography*, a town of Bohemia, in the circle of Konigingratz; 10 miles E. of Geyerſberg.

GRULING, Philip, in *Biography*, was a native of Stolberg, in Thuringia, a magiſtrate of that place, and phyſician to the count. He was a laborious man, and cultivated medicine from a taſte for the ſcience; and he took pleaſure in communicating the reſults of his ſtudies to the public. He died at his native place in the year 1667, at the age of 74. He left ſeveral publications on medical ſubjects, which were collected together, and reprinted at Leipſic, in 1680, under the title of "Opera Omnia." Eloy. Dict. Hiſt.

GRUMBACH, in *Geography*, a town of France, in the department of the Sarre, and chief place of a canton, in the diſtrict of Birkenfeld. The place contains 1061, and the canton 5892 inhabitants, in 38 communes.

GRUMBERG, a town of Moravia, in the circle of Olmutz; 6 miles N. of Hohenſtadt.

GRUME, Grumus, in *Medicine*, &c. a little maſs or lump of blood, milk, or other fluid, which is coagulated, thickened, hardened, &c.

Phthiſical people frequently ſpit up *grumes*, i. e. clots of blood.

Grumes of milk are what we popularly call *curds*.

GRUMAGNA, in *Geography*, a ſmall iſland in the gulf of Venice. N. lat. 44° 9′. E. long. 15° 18′.

GRUMOSE Roots, are thoſe which are compoſed of ſeveral ſmall knobs; ſuch are thoſe of the anemones, and of the little celandine.

GRUMOUS Blood, denotes that ſtate, or conſiſtence, of the blood, wherein it is too viſcid and thick, for a due, briſk circulation; the effects whereof are, that it ſtagnates in the capillary veſſels, and produces divers diſeaſes.

GRUNBERG, in *Geography*, a town of Germany, in the principality of Upper Heſſe; 10 miles E. of Gieſſen. N. lat. 50° 35′. E. long. 8° 58′.—Alſo, a town of Sileſia, in the principality of Glogau, ſurrounded with vineyards, and containing two churches. It has a manufacture of cloth; 20 miles N. of Sagan. N. lat. 51° 58′. E. long. 15° 35′.

GRUND, a town of Weſtphalia, ſituated in the Hartz foreſt; 12 miles S. W. of Goſlar.

GRUNDEL, or Grundling, *Grundulus*, in *Ichthyology*, a name uſed by ſome for the common loach, or loche, a ſmall freſh-water fiſh, known among writers by the names of *cobitis* and *fundulus*. See Cobitis *Barbatula*.

GRUNDLING, a name given alſo by the Germans to the *gobio fluviatilis*, or common gudgeon. See Cyprinus *Gobio*.

GRUNDSUND, in *Geography*, a town of Sweden, in Angermanland; 64 miles N. N. E. of Hernoſand.

GRUNEBERG, a town of Germany, in the New Mark of Brandenburg; 20 miles N. N. W. of Cuſtrin.

GRUNHAGEN, a town of Pruſſia, in Oberland; 6 miles S. of Holland.

GRUNHAYN, a town of Saxony, in the circle of Erzgeburg; 46 miles W. S. W. of Dreſden. N. lat. 50° 32′. E. long. 12° 45′.

GRUNIE, one of the ſmaller Shetland iſlands, in the cluſter called Out-ſkerries. N. lat. 60° 42′. W. long. 0° 44′.—Alſo, one of the ſmaller Shetland iſlands, S. of Unſt. N. lat. 61° 2′. W. long. 1° 8′.

Grunie *Half*, one of the ſmaller Shetland iſlands, S. of Unſt. N. lat. 61° 3′. W. long. 1° 5′.

GRUNINGEN, or Groningen, a town of Switzerland, and capital of a bailiwick, in the canton of Zuric; 12 miles S. E. of Zuric.—Alſo, a town of Weſtphalia, in the principality of Halberſtadt, on the river Boden; 15 miles E. of Halberſtadt. N. lat. 51° 55′. E. long. 11° 27.

GRUNNIENS Piscis, the *grunting fiſh*, the name of a fiſh caught in many parts of the Eaſt Indian ſeas, and called by the Dutch there *knorre-pot*. It ſeems of the gurnet or gurnard kind, and nearly related to the guabi-coara of the Braſilians. When it is firſt taken out of the water, it makes a remarkable *grunting-noiſe*. It has two ſide-lines on each ſide, running from the gills to the tail; the one of which is brown, and the other yellow; it is covered with very ſmall ſcales, and is a very fat and fleſhy fiſh; it grows to about ſix or ſeven inches long, and its head is large and ill-ſhaped; it is a very well taſted fiſh.

GRUNSTADT, in *Geography*, a town of France, in the department of Mont-Tonnerre, and chief place of a canton, in the diſtrict of Spire; 22 miles N.N.W. of Spire. It has three churches for Catholics, Lutherans, and Calviniſts. The place contains 2294, and the canton 14,727 inhabitants, in 29 communes. N. lat. 49° 32′. E. long. 8° 7′.

GRUNTHAL, a town of Saxony, in the circle of Erzgeburg; 17 miles S. of Freyberg.—Alſo, a town of Sileſia, in the principality of Breſlau; 4 miles N.N.E. of Newmarkt.

GRUNTTA, a town of Pruſſia, in the palatinate of Culm; 17 miles N.E. of Culm.

GRUPELLO, a town of Italy, in the department of the Gogna; 7 miles W. of Pavia.

GRUPPO, or Shake, in *Muſic*, was introduced into England by a gentleman who learned it of the famous Scipione del Palla, in Italy. It conſiſts in the alternate prola-

tion of two tones in juxta-position to each other, with a close on the note immediately beneath the lower of them. This is the chief grace both in vocal and instrumental performances.

GRUS, in *Antiquity*, a dance performed yearly by the young Athenians, around the temple of Apollo, on the day of the Delia.

The motions and figures of this dance were very intricate, and variously interwoven; some of them being intended to express the windings of the labyrinth wherein the Minotaur was killed by Theseus.

GRUS, in *Astronomy*, a southern constellation, not visible in our latitude. The number of stars in this constellation, according to Mr. Sharp's Catalogue, is 13. See CONSTELLATION.

GRUS, in *Ornithology*, a family of the Ardea or Heron genus; the grues of Buffon, and cranes of English authors.

Brisson places the grues with the storks, these collateral tribes forming, in the opinion of that naturalist, a genus distinct from the herons. The grues of some other continental authors differ from the storks, their characteristic distinction being taken from the form of the feet, the true grues having only the middle and outer toe connected by a membrane, while in the storks, the three anterior toes are united by a common membrane. The grues agree, in the structure of the feet, with the heron, and differs in the internal conformation of the body; the grues having a double cœcum, the herons only one; the former are also larger, and rather dissimilar in their manners of life. Some writers confine the term grues entirely to the cranes, a tribe known, according to Gmelin, by the baldness of the head; others adopt it in a more general manner, including among the grues the demoiselle, or Numidian crane, and also the crowned or Pavonian heron, in both which the head is crested. See HERON.

Species.

VIRGO. Behind each eye a tuft of long white pendent feathers. *Ardea virgo*, Linn. *La grue de Numidie, ou demoiselle*, Briss. *Numidian crane*, Albin. *Demoiselle of Numidia*, Edwards.

A large species, being about three feet three inches in length; the bill straight, yellowish, with the base green, and tip red; irides crimson; head, and primary quill-feathers black; feathers of the breast long and pendulous; crest over the eyes turned back, and pendulous; body blueish-ash; crown cinereous; head, neck, throat, breast, and legs black. This beautiful bird is found in Africa and Asia, and is frequently kept in European menageries, being of a docile disposition, and so easily inured to our climates and the rigours of confinement as to breed in that state of captivity. Its natural food is fish, worms, insects, and the smaller kinds of reptiles.

PAVONIA. Crest bristly, erect; temples with two naked wattles. *Ardea Pavonia*, Linn. *L'oiseau Royal*, Briss. *Balearic crane*, Ray. *Crowned African crane*, Edwards. *Crowned heron*, Lath.

The size of this species is equal to that of the common heron; the bill two inches and a half long, straight and brownish; irides grey. Crown covered with short, silky, black feathers; crest yellowish, tipped with black, and globular; the sides of the head bare of feathers, reddish, and kidney-shaped; and on each side of the throat a wattle of the same colour; the plumage generally blueish-ash; wing-coverts white, the greater ones reddish, those next the body blackish; tail and greater quill-feathers black; and the legs dusky. Those parts of the female which are cinereous blue, in the male are black; in the former the wattles are wanting, and the long feathers on the breast less conspicuous. This elegant bird inhabits Africa, and is often kept in our menageries; in its native state, worms, reptiles, and vegetables constitute its chief food; it runs and flies well, and often sleeps on one leg. The flesh is said to be very tough.

CANADENSIS. Forehead naked and papillous; body cinereous; wings testaceous on the outside. *Ardea Canadensis*, Linn.. *La grue de la baye d'Hudson*, Briss. *Blue crane*, Phil. Trans. *Brown and ash-coloured crane*, Edwards. *Brown crane*, Lath.

Length three feet three inches; the bill three inches and three quarters long, and dusky, with the tip of the upper mandible flesh-coloured; naked part of the head red; back, wings, and scapulars reddish; greater quill-feathers dark brown; legs black.

Inhabits North America, is of the migratory kind, and feeds on corn and insects. The flesh is in some esteem. A supposed variety is described of a cinereous colour, with the greater quill-feathers black.

GRUS. Hind-head papillous; cap and quill-feathers black; body cinereous; innermost tail-feather jagged. *Ardea grus*, Linn. &c. *La grue*, Briss. *Crane*, Ray, &c.

The crane is a bird of considerable size, often weighing ten pounds, and being in length above five feet: the bill is almost four inches and a quarter long, the colour greenish-black; the forehead to the middle of the crown covered with black down or hair, the hind part of the head bare and red, with a few scattered hairs on the nape, and below this a bare ash-coloured space; temples and upper parts of the neck white; general colour of the plumage grey; the legs black.

This species inhabits various parts of Europe and Asia, migrating in autumn towards the south, and in the winter visiting the northern regions, sometimes even as far as Britain. It flies in vast flocks, and frequently so high as to be scarcely visible. Its food consists of reptiles and fishes, and the green corn among the latter of which it is said to make great havock. A variety, the colour of which is white, with the lower part of the neck and quill-feathers black, is described as a native of Japan.

AMERICANA. Crown, nape, and naked temples papillous; front, nape, and primary quill-feathers black; body white. *Ardea Americana*, Linn., &c. *La grue d'Amerique*, Briss. *La grue blanche*, Buff. *Hooping crane*, Catesby.

Native of North America; the length four feet six inches; bill yellowish, and serrated at the tip; crown red, covered with black hair, head beneath as far as the lower jaw red; legs black. The species inhabits marshes, and feeds on worms and insects.

ANTIGONE. Naked; head and papillous collar red; body cinereous; primary quill-feathers black. Linn. *La grue des Indes Orientales*, Briss. *Greater Indian crane*; Edwards.

A larger bird than the common crane. The bill greenish yellow, with dusky tip; irides reddish hazel; crown of the head and spot behind the eyes white; the quills black; secondaries and tail ash-colour; legs red, with white claws. Inhabits India and the adjacent parts of Russia, to the western extremity of the Gobean plains. A variety of this species, rather less in size, is found in the East Indies, the body of which is blueish-ash; the bill and tail black, and the legs dusky. Another kind, recently discovered in New South Wales, has the bill and lower part of the head yellow,

yellow, the reſt of the head naked and red; throat covered with black hairs; plumage in general pale blue; wings and tail black, legs blackiſh.

Leucogeranos. White, temples and front naked, red, and wrinkled; the firſt ten quill-feathers ſhining black, bill and legs red. Pallas Travels. *Ardea gigantea*, Lath. *Siberian crane.*

The length of this bird is about four feet ſix inches; the bill like that of the crane, but larger, red, with the mandibles ſerrated near the tip; irides pale whitiſh; tail with twelve nearly equal feathers. The plumage ſnowy white, except the quill-feathers and coverts.

This ſpecies inhabits the vaſt marſhes of Siberia; feeds on reptiles, worms, and fiſhes; and builds its neſt upon riſing graſſy tufts, in the moſt inacceſſible places. The neſt is compoſed of herbs and graſs; the eggs are two in number, the ſize of thoſe of a gooſe, of an aſh-colour, and ſpotted with brown. It is of a ſhy diſpoſition, and aſſociates in large flocks, each of which has a centinel conſtantly on the watch, to apprize their companions of the approach of danger. The Ruſſians know this bird by the name of *Sterchi.*

Grus *Balearica.* See Grues and Pavonina.

GRUSUE, in *Geography*, a town of Norway, in the dioceſe of Aggerhuus, on the Glanmen; ſix miles N. of Berga.

GRUTER, John, in *Biography*, an eminent philologiſt, was born at Antwerp in 1560. His father, who was burgomaſter there, was obliged, in the troubles of his country, to take refuge in England. He was educated by his mother, who was a very excellent ſcholar, and was miſtreſs of many of the modern, as well as the ancient languages. He ſtudied ſome years at Cambridge, and thence he went to Leyden, where he attached himſelf ſolely to polite literature, and at a very early age he publiſhed works on criticiſm. After travelling very much he became profeſſor in the univerſity of Heidelberg, and had the direction of its famous library. At the ſack of this city, in 1622, he ſuffered the loſs of his own library worth 12,000 crowns, together with moſt of his other property. When the affairs of the palatinate were ſomewhat ſettled, he took a country-houſe near Heidelberg, where he died in 1627, having upon his death-bed received an invitation to the Greek and hiſtory profeſſorſhip at Groningen. He wrote many works, of which the moſt conſiderable are; 1. "A Collection of ancient Inſcriptions;" 2. "Theſaurus Criticus;" 3. "Deliciæ poetarum Gallorum, Italorum, et Belgarum," &c.

GRUTLIN, in *Geography*, a plain of Switzerland, near the lake of the four cantons, in the canton of Uri, celebrated as the place where the three firſt cantons made a league for the defence of their liberty, in the year 1307.

GRUYERES, a bailiwick of the canton of Friburgh in Switzerland. The cheeſe, well known under the name of Gruyeres, which is exported in large quantities, is made on a chain of mountains about 10 leagues in length and four in breadth, extending from the bailliage of Schwartzenburgh to the diſtricts of Vevay and Aigle, in the canton of Bern. The whole diſtrict is divided into greater or leſſer farms, let out by the proprietors on leaſes of three or ſix years, at a certain annual rate during five months for each cow, according to the nature or elevation of the ground. Each farmer, having rented a mountain, hires from the different peaſants in the cantons from 40 to 60 cows from May 15th, to October 8th; each cow yields at an average daily from 20 to 24 quarts of milk, and ſupplies 200lbs. of cheeſe during the five months. The cows are then reſtored to the different proprietors. As the mountains in the canton of Friburgh afford paſture for at leaſt 15,000 cows, it may be eſtimated that they annually ſupply about 30,000 hundred weight of cheeſe fit for exportation; beſides 2000 or 3000 after their return from the mountains, excluſive of a thinner ſort, made in various parts of the canton. The cheeſes fit for exportation weigh from 40 to 60 pounds each, and are ſold from 1*l.* 17*s.* to 2*l.* per cwt. Theſe cheeſes are exported in caſks containing 10 of them. Thus packed they will bear being tranſported into the moſt diſtant countries; but they ſhould be kept in a damp place, and frequently waſhed with white wine, to preſerve them from inſects. Gruyeres is 15 miles S. of Friburgh. N. lat. 46° 36. E. long. 6° 53'.

GRY, a meaſure containing one-tenth of a line.

A line is one tenth of a digit, and a digit one-tenth of a foot, and a philoſophical foot one-third of a pendulum, whoſe diadromes, or vibrations, in the latitude of forty-five degrees, are each equal to one ſecond of time, or one ſixtieth of a minute.

GRYGALLUS, in *Ornithology*. See Grouse.

GRYHITTE, in *Geography*, a town of Sweden, in Weſtmanland; 58 miles W.N.W. of Stroemſholm.

GRYLLE. See Colymbus *Grylle.*

GRYLLOTALPA, in *Entomology*. See Gryllus.

GRYLLUS, the name of an extenſive genus of the Hemiptèra order in the Linnæan ſyſtem; a genus of Ulonata in that of Fabricius, and one of the Orthoptera of Lamarck and other late writers.

The Linnæan character of the gryllus tribe conſiſts in having the head inflected, and armed with jaws; feelers filiform; antennæ ſetaceous or filiform; wings four, deflected and convoluted, the lower ones plaited; poſterior legs formed for leaping, and the claws double on all the feet.

This diffuſe and very general character includes ſeveral diſtinct families, and ſome of theſe ſo exceedingly diſſimilar, that Linnæus was conſtrained to divide his grylli into no leſs than five ſections or ſubdiviſions for their reception; theſe are his acridiæ, bullæ, achetæ, tettigoniæ, and locuſtæ, the characters aſſigned reſpectively to each of which are as follow.—The *acridiæ* have the head conic, and longer than the thorax; and the antennæ enſiform or ſomewhat reſembling a ſword.—The *bullæ* are diſtinguiſhed by a kind of creſt or elevation on the thorax, and the ſize as well as ſtructure of the antennæ, which are ſhorter than the thorax, and filiform.—The *achetæ* are thoſe furniſhed with two briſtles above the extremity of the abdomen.—*Tettigoniæ*, in which the extremity of the abdomen in the females are diſtinguiſhed by a kind of tube, through which they depoſit their eggs in the ground; the antennæ in both ſexes ſetaceous.—*Locuſtæ* have the tail ſimple or without briſtles, as in the achetæ, or the tube that terminates the tail of the females in the tettigoniæ; the antennæ in this family are filiform.

Geoffroy conſiders moſt of theſe families as generically diſtinct, and accordingly ſeparates them. The achetæ of Linnæus he retains under the name of gryllus, adding at the ſame time to the Linnæan character that they have three ſtemmata, (or little eyes on the back of the head,) and that the feet conſiſt of three articulations. The Linnæan locuſtæ are the acrydiæ of Geoffroy, with the additional obſervation, that the antennæ are one-half ſhorter than the abdomen, the ſtemmata three in number, and the joints of the feet alſo three, as in the preceding. The *locuſtæ* of Geoffroy are the tettigoniæ of Linnæus, or at leaſt thoſe which have the antennæ filiform and longer than the abdomen; and the feet containing

containing four joints. This ſubdiviſion of the Linnæan grylli is adhered to by Schæffer without material variation.

In the Fabrician claſſification, the Linnæan grylli are divided into five genera, nearly after the example of Geoffroy. The diſtinctions of his genera are however different, theſe being conſtructed according to his manner from the ſtructure of the feelers, lip, and antennæ. Thus his genus *acrydium* has the feelers equal and filiform; the lip ovate with the tip ſplit; and the antennæ filiform. *Acheta*, feelers unequal and filiform; lip quadrifid, the lateral pieces dilated and rounded, and the antennæ ſetaceous. *Locuſta*, feelers unequal and filiform; jaws three-toothed at the tip; lip bifid, the projections ſubulate briſtle, and the antennæ filiform. *Gryllus*, feelers equal and filiform. Beſides the above, Fabricius forms a new genus under the name of *tetrix*, conſiſting of thoſe which have the feelers filiform; the lip bifid, with the projections equal, and the antennæ enſiform. Thunberg previouſly to the publication of the Fabrician Ent Syſt. inſtituted another genus under the name of *Pneumora*, but theſe Fabricius rather inconſiderately incorporates in the laſt-mentioned work, as appertaining to the grylli of his ſyſtem; we however agree with Thunberg, and with Gmelin, the latter of whom introduces it as a diſtinct genus between the blattæ and mantes, in his edition of the Linnæan Syſtema Naturæ.

Latreille forms three diſtinct families of the grylli as comprehended under the Linnæan term, and which he denominates gryllidæ, locuſtariæ, and acrydiana. The grylliæ are divided into three genera, tridactylus, gryllotalpa, and gryllus. The locuſtariæ contains only the locuſta genus. And the acrydiana four genera; namely, pneumora, truxalis, acrydium, and tetrix.

Hence it will appear that in the progreſſive advancement of natural ſcience ſince the time of Linnæus, the inſects which that naturaliſt deſigned to unite in one genus have been gradually ſeparated into five, ſix, and laſtly into eight ſeveral genera. It muſt however be recollected, that the number of ſpecies known to Linnæus was comparatively ſmall, not amounting altogether to one-tenth portion of thoſe deſcribed by Fabricius and other late authors. The arrangement he propoſed might therefore with ſome propriety be deemed adequate to the diſtribution of the ſpecies known to that author, though it may not be entirely admiſſible at this period. Our knowledge of theſe natural tribes of inſects has been indeed ſo much extended of late years, as to leave room in our own opinion to doubt the propriety, or rather the neceſſity of adopting ſeveral of the genera recently eſtabliſhed, with ſome degree of modification. Theſe, to avoid a ſomewhat unneceſſary diſtribution of the articles, we propoſe to conſider under one general term, and none appears more applicable to the purpoſe than that of gryllus, the extenſive acceptation of which is generally underſtood by every ſtudent in entomology.

Moſt of the gryllidæ feed on vegetables, except thoſe of the tribe tridactylus, which prey on other inſects. In the larva and pupa ſtate they nearly reſemble the perfect inſect; the larvæ differing only in being entirely deſtitute of wings and wing-caſes, and the pupæ in poſſeſſing merely the rudiments of theſe members; they are active and voracious, and ſubſiſt, as in the adult ſtate, on vegetables.

Genus Acheta.

Antennæ ſetaceous, and compoſed of many joints; feelers unequal and filiform; lip four-cleft; head ſmall; thorax roundiſh; eyes ſcated; body thick and cylindrical, the tail with two briſtles; legs ſhort and thick; the anterior feet generally formed for digging.

GRYLLOTALPA. Wings tailed, and longer than the abdomen; anterior feet palmated. Linn. *Mole-cricket*, Donov. Brit. Inſ. &c.

Inhabits gardens, where it burrows under the ſurface of the ground like the mole, and occaſions conſiderable miſchief by gnawing and devouring the roots of plants. The length is about three inches; the body livid brown, and hairy; wing-caſes ſhort and reticulated. This kind inhabits Europe; an apparent variety of the ſame is found in America.

MONSTROSA. Wing-caſes and wings terminated in a convoluted tail. Fabr. Donov. Inſ. India.

Much larger than the foregoing ſpecies, and very ſingular in form; the antennæ are longer than the body; ſhanks ſpinous; feet dilated and divided into lobes.

DOMESTICA. Wings tailed, longer than the wing-caſes; body glaucous. Linn. Degeer, Donov. Brit. Inſ. &c.

The common or domeſtic cricket is an inhabitant of houſes about ovens and kitchen chimneys, preferring theſe ſituations for the ſake of warmth; the preſence of the cricket is eaſily known by its continual chirping, the ſound of which is vulgarly ſuppoſed to be loudeſt before rain. It is very common throughout Europe, and ſeems in many parts to have obtained a kind of indulgent reſpect from the peaſantry, who conſider its reſidence in their houſes as a token of good fortune.

ASSIMILIS. Wings tailed, and longer than the wing-caſes; abdomen with two ſtyles, the tip cleft. Fabr.

Size of the common cricket; the antennæ pale; thorax and head black with a pale edge; wing-caſes rounded, and brown; abdomen black; ſtyles or ſpinous projections filiform, and as long as the abdomen; legs brown. Native of Jamaica.

RETICULATUS. Black; wing-caſes reticulated with rufous; antennæ annulated with white. Fabr.

Inhabits Africa. The antennæ are twice the length of the body, black, with ſeven white rings; head yellowiſh; crown black; thorax black, with a yellow ſpot in the middle; wing-caſes ſhort and obtuſe; abdomen black: ſtyles two, villous, with an aſcending ſpine.

BRASILIENSIS. Wings tailed, and longer than the wing-caſes; body brown, paler on the back; tail aſcending, and as long as the body. Fabr.

The head is brown, paler on the crown; thorax browniſh at the ſides, and pale above; wing-caſes with a lateral black ſpot; abdomen with a yellowiſh projection, brown at the end. Native of South America.

ORIENTALIS. Wings tailed, longer than the wing-caſes, and white; body deep black; head and legs [illegible]. Fabr.

Native of Tranquebar. Thorax rounded; wings brown at the tip; ſtyles longer than the abdomen; legs black and yellowiſh.

FLAVIPES. Wings tailed green, and longer than the wing-caſes; legs yellowiſh. Fabr.

Inhabits St. Thomas's iſland in America. The head and thorax are yellowiſh; wing-caſes green, with a yellowiſh margin; filaments of the tail as long as the abdomen, black, thick at the tip and bifid.

CAFFRUS. Wings tailed, and longer than the wing-caſes; body black; wing-caſes brown, the baſe yellow. Fabr.

Reſembles the field cricket, and inhabits Africa.

MONO. Wings tailed, longer than the wing-caſes; white with the tip black; body deep black. Fabr.

Native of Africa. The eyes teſtaceous; wing-caſes rounded at the tip; tail with a long filiform ſpine.

CAN-

Campestris. Wings ſhorter than the wing-caſes; body blackiſh; ſtyle linear. Linn.

Inhabits Europe, and chirps from the beginning of May till the equinox.

Umbraculata. Black; wing-caſes white at the tip; front covered with an obovate deflected membrane. Linn.

Smaller than the laſt, and inhabits Barbary. Head ferruginous, the deflected membrane black; ſtyles villous; legs black. This ſpecies is deſtitute of wings.

Hospes. Wings tailed, and longer than the wing-caſes, white with a brown rib; wing-caſes white ſpotted with black. Fabr.

Native of America. The antennæ brown, and a little longer than the body; head and thorax black; abdomen black; tail with a ſpinous recurved projection, nearly as long as the body; legs brown; poſterior ſhanks ſpinous at the tip.

Crucis. Wing tailed, and longer than the wing-caſes; body brown; margin of the wing-caſes dotted with black. Fabr.

Inhabits the iſland of Santa Cruz. The head and thorax fuſcous, the margin of the latter yellow; wings whitiſh; antennæ thrice as long as the body.

Guadeloupensis. Wings without tails; body brown; legs pale. Fabr.

Small; thorax marked with a large yellowiſh ſpot; wings and wing-caſes equal; legs yellow; hind claws ſerrated. Inhabits Guadaloupe.

Italica. Head and thorax yellowiſh; wing-caſes aqueous, and as long as the wings. Fabr.

Antennæ longer than the body; eyes black; anterior legs yellowiſh, the poſterior ſpinous, with ſpinous ſhanks. Native of Italy.

Minuta. Thorax rounded and yellowiſh; wings tailed; tail with two briſtles; poſterior ſhanks three-ſpined. Linn.

Inhabits America.

Sylvestris. Apterous, black; wing-caſes vaulted, very ſhort, and cinereous with fuſcous lineations. Fabr.

Thorax pale with the edge blackiſh; abdomen black, with a recurved ſpine longer than the two ſtyles. A ſmall ſpecies found in France.

Fossor. Wing-caſes very ſhort, with the tip deep black; anterior legs palmated. Fabr. App.

Native of the Cape of Good Hope. This ſpecies is ſmall; head and thorax grey and immaculate; wings long, at the baſe white, tip brown; abdomen banded above with black and white, beneath grey; anterior legs ſhort.

Maculata. Wings tailed, rather longer than the wing-caſes, and brown; head and thorax teſtaceous with black ſpots. Fabr. App.

The antennæ are brown; head gibbous and black, the crown teſtaceous, with five black lines; thorax teſtaceous, varied with ſpots and dots of black; wings white; body brown, the tail furniſhed with two briſtles, and without ſtyles. Inhabits the Eaſt Indies.

Aquea. Wing-caſes white and hyaline; wings ſhort; body yellowiſh. Fabr. App.

Inhabits Ruſſia. The body entirely yellowiſh, and immaculate; wing-caſes ovate.

Genus Locusta.

Antennæ ſetaceous, and of many joints; feelers unequal, and filiform jaw tridentated at the tip; lip bifid; head large and ovate; no ſcutel; wing-caſes compreſſed and membranaceous; abdomen elongated and compreſſed, that of the male terminated in four ſhort ſtyles, the female with an enſiform tube; poſterior legs long and formed for leaping; tarſi of four joints.

Species.

Amboinensis. Green; thorax quadrangular, with the angles dentated; ſcutel large, brown-green; wing-caſes leaf-formed, and very broad. Donov. Inſ. India.

A new ſpecies, and in point of ſize one of the moſt conſiderable of its family; the length, from the front of the head to the extremity of the wing-caſes, being about ſeven inches, the legs long, and the antennæ about the ſame length as the body. The individual ſpecimen deſcribed and figured in the above work is at preſent in the magnificent collection of A. M'Leay, eſq. and is probably unique. It was originally received from Amboyna by governor Holford, then reſident in India, and has for that reaſon been generally conſidered as a native of that iſland.

The wing-caſes, and alſo the poſterior part of the thorax, are of a fine and delicate green; the anterior part of the thorax yellowiſh-brown; and the head and body ſtill paler. The wing-caſes, as uſual in this tribe, bear no very diſtant reſemblance to the leaves of certain plants, not only in colour, but alſo in outline, and ſtill more ſo in the conformation of the nerves, which ariſe and branch off towards the extremities, exactly in the ſame manner as the nerves ariſe and ramify from the mid-rib in the far greater number of plants. One peculiarity in the ſtructure of the wing-caſes in this new ſpecies deſerves remark; the ſcutel, or rather that portion of the wing-caſes on the left ſide which folds over the back when at reſt, is of a much ſtronger texture than any other part of the inſect, except the thorax, and ſerves as an external covering or defence to the correſponding lobe of the other wing-caſe, which is of a more delicate nature, conſiſting only of a thin and pellucid membrane, the ſurface of which is hyaline or glaſſy. The wings are remarkably tender, whitiſh, and ſemi-tranſparent. Vide Donov. Ind.

Citrifolia. Thorax nearly quadrangular, the angles crenated. Fabr. *Thorace tetragono angulis ſcabro*, Linn. *Locuſta viridis*, Degeer. *Citron-leaved locuſt*, Donov. Inſ. India.

About half the ſize of the laſt.

Wing-caſes green with reddiſh nerves, and in form reſembling the leaf of a plant; antennæ long. Native of the Spice iſlands.

Laurifolia. Thorax nearly quadrangular and ſmooth; wings lanceolate, and longer than the wing-caſes. Fabr. *Gryllus laurifolius*, Linn. *Locuſta oblongifolia*, Degeer. *Tucurubi*, Marcgr.

Deſcribed by Sloane as a native of Jamaica, and is alſo found in other American iſlands. The wing-caſes are gibbous and green, with reddiſh nerves, and in appearance reſembles a leaf; legs greeniſh.

Myrtifolia. Thorax nearly triangular and ſmooth; wings deflected, and longer than the wing-caſes; ſword very ſhort and recurved. Fabr. Drury.

Native of America, and ſmaller than the preceding; tail of the male with a clavated, forked lamina; ſword of the female very ſhort, and recurved.

Fenestrata. Thorax ſmooth; wing-caſes green, with a tranſparent-ocellar ſpot at the baſe; legs ſpinous. Fabr.

Large, and inhabits the Eaſt Indies; the antennæ are very long and brown; head varied with black and brown; thorax green, behind rounded and black; wing-caſes with two ſpots in the middle and three ſmall ocellated ſpots; body greenſh, with a ſharp tooth on the back.

Cancellata. Thorax deflected; wing-caſes concave, rounded

rounded at the tip, and longer than the wings. Fabr. *Locuſta ſiccifolia*, Degeer.

Middle ſize; head large, greeniſh; thorax of three ſegments, deflected at the ſides, and rounded behind; wing-caſes large and green; wings large and greeniſh; abdomen greeniſh; ſword aſcending, green, with the tip brown; legs green; thighs ſpinous. Native of America.

Oleifolia. Front pointed; thorax ſub-carinated; wing-caſes concave, green, and ſhorter than the wings. Fabr.

Native of Tranquebar. Size moderate; antennæ yellowiſh; body brown.

Thymifolias. Thorax quadrangular and ſmooth; wing-caſes nearly linear, dotted with brown, and ſhorter than the wings. Fabr.

Inhabits New Holland. Thorax greeniſh, with a lateral brown line, and emarginate behind; wings whitiſh, with the tip greeniſh.

Graminifolia. Head pointed; thorax ſquare; wing-caſes filiform, brown and ſhorter than the wings. Fabr.

A ſmall ſpecies, found at the Cape of Good Hope; the antennæ ſhorter than the body; abdomen greeniſh; the ſword ſtraight and green, tipped with brown.

Lilifolia. Thorax ſquare and ſmooth, with two yellow lines; wing-caſes green and ſhorter than the wings. Fabr.

Native of Italy and ſmall; antennæ twice the length of the body; head green; wing-caſes longer than the body; ſword very ſhort, recurved, brown and finely ſerrated each ſide; legs green; ſhanks ſpinous.

Salvifolia. Thorax ſmooth; wing-caſes lanceolate, concave, and green; wings rounded and red. Linn. Tranſ.

Country unknown.

Perspicillata. Thorax deflected; wing-caſes concave and green, with an ocellar dorſal tranſparent ſpot at the baſe. Fabr.

Inhabits America. Head pale; antennæ fuſcous; thorax green; wing-caſes large; legs green and ſpinous.

Serripes. Thorax rounded and green; wing-caſes and wings equal; fore-legs very ſpinous. Fabr.

Native of Amſterdam iſland. The antennæ long and pale; head between the eyes pointed; thorax immaculate; wing-caſes greeniſh; wings pale.

Spinipes. Thorax rounded; wing-caſes green, hyaline, and ſhorter than the wings; anterior legs ſpinous. Fabr.

A Braſilian ſpecies of ſmall ſize; antennæ length of the body; head rather pale; eyes very prominent; wing-caſes obtuſe; body brown; anterior thighs and ſhanks armed with long ſpines.

Maxillosa. Green; antennæ and jaws yellow. Fabr.

Native of America. Head pointed, with a yellow dot at the tip; antennæ as long as the body; thorax glabrous; wing-caſes and wings twice the length of the body; poſterior ſhanks denticulated.

Elongata. Thorax nearly ſquare and ſmooth; wing-caſes and wings grey, and the ſame length as the abdomen, Linn.

Inhabits India.

Femorata. Thorax rough and grey; wings lanceolate, and ſhorter than the obtuſe wings; thighs membranaceous, and toothed beneath. Fabr.

Thorax rounded before and behind, and ſcabrous, with ſharp raiſed dots; ſword ſtraight, ſhort and black, with the ſides rufous. Native of Tranquebar.

Italica. Thorax deflected; wing-caſes green, and as long as the wings; head whitiſh. Fabr.

A ſmall ſpecies found in Italy. The antennæ are ferruginous; thorax ſmooth and greeniſh; wing-caſes flat and browniſh on the back; body yellowiſh; ſword ſtraight and longer than the body.

Specularis. Thorax rounded; wing-caſes grey, with a tranſparent ocellar dorſal ſpot at the baſe; antennæ very long.

Native of South America.

Perforata. Thorax deflected; wing-caſes linear and grey, with the ocellar dorſal ſpot at the baſe perforated; wings white and black, varied. Fabr.

A ſpecies of moderate ſize, found at the Cape of Good Hope.

Ocellata. Thorax rounded; wings with an ocellar mark. Linn.

Inhabits India.

Lanceolata. Thorax rounded and ſmooth; wing-caſes oblong, and length of the wings; front advanced and lanceolate; beneath with a ſingle tooth. Fabr.

Native of Sierra Leona.

Pallens. Thorax ſmooth and whitiſh; wings lanceolate, and longer than the wing-caſes. Fabr.

A ſmall ſpecies found in Cayenne.

Acuminata. Thorax rounded, and emarginate at the ſides; crown ſubulate; wings greeniſh, and as long as the abdomen. Linn. Donov. Inſ. China, &c.

Inhabits China and other parts of Aſia.

Conocephala. Thorax rounded and ſmooth; wing-caſes oblong, and ſhorter than the wings; head conic and obtuſe. Linn.

Body green; head and thorax with a fuſcous dorſal line; ſword ferruginous. Native of Africa.

Triops. Crown pointed, with an ocellar black dot beneath; wing-caſes and wings equal. Linn.

Inhabits India.

Coronata. Thorax crowned with erect ſpines; wing-caſes with large hollow fuſcous dots; wings fuſcous. Linn. Degeer, &c.

Native of India. The antennæ pale yellow and grey varied.

Coriacea. Thorax rounded and ſmooth; wing-caſes coriaceous; wings pale; antennæ very long. Fabr.

Inhabits the ſame country as the latter.

Melanoptera. Thorax rounded and ſmooth; wing-caſes half as long as the abdomen; wings black. Linn.

Wing-caſes ovate; wings black at the margin, the baſe teſtaceous. The ſpecies inhabits India.

Reticulata. Thorax of three ſegments; wing-caſes reticulated; wings fuſcous; antennæ very long. Fabr.

A large ſpecies, found in Guadaloupe.

Albifrons. Thorax ſmooth and rounded behind; wing-caſes cinereous and black varied; head pale; ſword ſerrated at the tip. Fabr.

Native of Madeira. The body large and brown; head obtuſe; thorax brown with pale margin; wings hyaline.

Falx. Thorax ſmooth, fuſcous, and rounded behind; head pale; ſword falcated and black. Fabr.

Native of the ſame place as the former.

Grisea. Fuſcous; thorax carinated behind and rounded; ſword falcated, black at the baſe, and pale each ſide. Fabr.

Inhabits

Inhabits Italy.

VIRIDISSIMA. Green and without ſpots; antennæ very long. Linn. *Locuſta viridis cantatrix*, Degeer. *Agrigoneus*, Liſt. *Green locuſt*, Donov. Brit. Inſ. &c.

Inhabits Europe, chiefly among graſs.

VERRUCIVORA. Green; wings ſpotted with brown; antennæ as long as the body. Linn.

Like the former inhabits Europe, and is chiefly found among graſs.

GLADIATOR. Thorax rounded; wings linear, pointed, longer than the wing-caſes; poſterior thighs with a black ſpot at the tip. Fabr.

Native of Tranquebar. Antennæ much longer than the body, and with the head teſtaceous; thorax rounded, teſtaceous, with black dorſal blotches; wing-caſes hyaline and reticulated; ſword advanced, ſtraight, narrow, and teſtaceous.

VARIA. Thorax green, with a yellow line down the middle; front pointed; antennæ very long. Fabr. *Locuſta thalaſſina*, Degeer. *Variable locuſt*, Donov. Brit. Inſ.

About half the ſize of the common green locuſt or graſs-hopper. The antennæ yellowiſh; crown of the head clavated and acute; wing-caſes green; ſword aſcending and brown. Inhabits Britain and other parts of Europe.

BRACHYPTERA. Grey-brown; wing-caſes and wings half as long as the body. Fabr. *Gryllus brachypterus*, Linn.

Inhabits Europe, eſpecially the northern part, and feeds on graſs; ſword elongated and curved.

SERRATA. Thorax ſmooth and green; thighs and ſhanks of the anterior legs ſerrated; body apterous. Fabr.

According to Hybner a native of Hungary. The body is large; thorax green, at the ſides yellowiſh; antennæ longer than the body, and teſtaceous; ſword ſtraight, and ſhorter than the abdomen.

FUSCA. Green; wing-caſes fuſcous, and as long as the wings; front advanced and obtuſe. Fabr.

Native of France; in ſize and appearance reſembles the ſpecies Varia; the antennæ as long as the body and fuſcous; head green, with a black dorſal line; thorax deflected; wings hyaline; body green; ſword teſtaceous, and as long as the abdomen.

PUPA. Thorax ciliated with ſpines; abdomen tuberculated, and ſpinous; body apterous. Linn. &c. *Locuſta pupa ſpinoſa*, Degeer.

Inhabits Ethiopia. The ſcutel large, and rounded; poſterior thighs armed beneath with four ſpines or teeth.

SPINULOSA. Thorax thorny, and ſurrounded with ſpines; body apterous. Linn. &c.

Native of the Indies. Antennæ as long as the body; abdomen black, with teſtaceous ſpots; ſword recurved.

ONOS. Thorax ſmooth and black; ſides grey; body apterous. Pallas, &c.

Inhabits Siberia. Sword the length of the abdomen.

EPHIPPIGER. Thorax elevated behind; wing-caſes very ſhort and vaulted. Act. Berol.

Found in the ſouthern parts of Europe. Antennæ thrice the length of the body; head green, behind grey; thorax yellowiſh at the ſides, the poſterior margin dilated; abdomen cylindrical, and black; the ſword recurved and yellowiſh at the tip; legs fuſcous, thighs yellow beneath.

APTERA. Wing-caſes very ſhort, vaulted, and whitiſh; front black, with ferruginous dots. Fabr.

Native of Italy. The antennæ black, and twice the length of the body; head black; thorax on the back flat, and teſtaceous, the ſides black, and the margin teſtaceous; abdomen pale, with the ſides black; legs black, poſterior thighs edged at the baſe with pale.

PEDESTRIS. Thorax ſmooth, and rounded behind; wing-caſes very ſhort, the tip with the head whitiſh. Fabr.

Inhabits ſame country as the former. The antennæ are ſetaceous, as long as the body, brown, with the baſe pale; abdomen fuſcous, with two dorſal lines of ferruginous dots.

LAXMANNI. Thorax dentated at the poſterior margin; ſword recurved, the tip deflected; female apterous. Pallas.

Native of Siberia.

SERRICAUDA. Green; thorax with a lateral ferruginous line; wing-caſes very ſhort; ſword recurved and ſerrated. Fabr.

Inhabits Italy.

HEMIPTERA. Wing-caſes green, compreſſed, half the length of the abdomen; ſword recurved, the margin entire. Fabr.

Native of the iſle of France.

MARGINATA. Apterous and black; thorax flat, with ſerrated dilated margin. Fabr.

Inhabits Ruſſia. Small and entirely black; antennæ ſetaceous; thorax large, abdomen very ſhort.

Genus GRYLLUS.

Antennæ filiform; feelers equal and filiform; lip rounded and bifid; head vertical; thorax flat above, and ſometimes carinated, the ſides deflected; body elongated; no ſcutel; wing-caſes the length of the abdomen, and membranaceous; poſterior legs long and formed for leaping; the tarſi of three joints.

Species.

ELEPHAS. Thorax carinated and entire; body apterous. Linn.

A large ſpecies, found in Africa; the general colour pale brown, varied with fuſcous; ſurface ſprinkled with elevated dots, and pointed prominencies, and the poſterior legs very ſpinous.

SUCCINCTUS. Keel and hind margin of the thorax, with the dorſal margin of the wing-caſes, yellow; throat horned. Linn.

Antennæ pale yellow; poſterior ſhanks ſpinous, pale yellow, and deep black at the tip. An Indian inſect.

CRISTATUS. Thorax creſted; keel four-cleft; wings fuſcous at the tip. Linn.

Length about eight inches, and meaſuring in breadth nearly ten inches when the wings are expanded; the wing-caſes are dull green, with yellow ſpots; wings pale, with ſtreaks of greeniſh; body and legs red. Inhabits the Arabian deſerts.

DUX. Thorax carinated and rough; wing-caſes green; wings rufous, ſpotted with brown. Fabr.

Native of South America; the antennæ black; head yellowiſh; thorax greeniſh with pale raiſed dots; wing-caſes with yellow nerves; poſterior margin of the wings brown; body and legs greeniſh.

CARINATUS. Thorax carinated; creſt trifid; wings with a black band. Fabr. Donov. Inſ. India.

Firſt diſcovered in the Eaſt by Forſkall The thorax is rough; wing-caſes greeniſh; poſterior thighs carinated each ſide, rough and reticulated with raiſed lines; ſhanks very ſpinous.

LUNUS. Segments of the thorax with ſemi-orbicular creſt; wing-caſes black with white bands. Linn.

Native of South America; wings black, and without ſpots.

RETICULATUS. Thorax boat-ſhaped, lengthened, and acute

acute behind; wing-cafes reticulated. Fabr. Donov. Inf. India.

Defcribed by Fabricius from the example in the Bankfian cabinet, delineated in the laft mentioned work. This fpecimen was found in Tranquebar; the head is ferruginous, the mouth fpotted with black; antennæ ferruginons, the firft and laft joints black; thorax with a trifid creft, its colour ferruginous, with the keel, and fhort line on each fide, black; wing-cafes dark, the reticulations yellow; legs black, beneath rufous.

Gallinaceus. Thorax boat-fhaped, very large, lengthened at each end, and with the wing-cafes brown and immaculate; pofterior thighs compreffed and ferrated. Fabr.

Native of the Eaft Indies; the antennæ are very fhort, and brown; thorax compreffed, covering the head and more than half the body; wing-cafes flexuous at the outer margin; wings yellowifh, pointed and brown at the apex; pofterior fhanks fpinous at the tip.

Serripes. Thorax boat-fhaped, and produced behind; wing-cafes fufcous; pofterior thighs ferrated. Fabr.

Defcribed from the cabinet of Daldorff. This kind of locuft inhabits India. The front is flat; head and thorax brown, varied with paler; carination of the thorax much elevated, acute, and impreffed each fide; pofterior thighs cinereous, and ferrated above; fhanks fpinous.

Serratus. Thorax boat-fhaped, carinated, ferrated, lengthened, and fharp behind. Fabr. *Gryllus ferratus*, Linn. *Acrydium ferratum*, Degeer.

Head pointed; abdomen blue. Native of Africa.

Turcicus. Thorax boat-fhaped; body cinereous; wing-cafes with a brown band, and bafe; wings at the bafe black. Fabr.

One of the fmalleft of this family. The head is cinereous, and withont fpots; thorax cinereous, with fmooth teftaceous keel; tip of the wings, with the legs cinereous. Native of India.

Miliaris. Thorax nearly fquare, and warty; wing-cafes with white callous dots. Linn. *Acrydium verrucofum*, Degeer.

Native of America.

Morbillosus. Thorax fquare, warty, and red, wing-cafes brown, dotted with yellow; wings red with black dots. *Gryllus morbillofus*, Linn. Donov. Inf. China.

A beautiful fpecies, and of confiderable magnitude, found in various parts of China in great plenty, and thence extending over other Afiatic countries, and into Africa. The antennæ are filiform and black; the head and legs fcarlet.

Cinctus. Thorax fpinous; wing-cafes obfcure; wings rufous with black fpots. Fabr.

Native of Senegal; the antennæ black; head yellowifh; thorax yellowifh, with many fpines of various fize, the pofterior part rounded and fringed with fpines; fpots on the wings numerous.

Leprosus. Thorax fomewhat fpinous, with two tubercles before; wing-cafes varied with blueifh and yellow. Fabr.

Deferibed from a fpecimen in the Bankfian cabinet; the head is pale, and fpotted anteriorly with black; antennæ black; thorax rounded behind; legs pale, thighs dotted with black without. Country unknown.

Punctatus. Thorax verrucofe; wing-cafes black, with yellow dots; wings black. Fabr. *Gryllus punctatus*, Donov. Inf. India.

Native of the Eaft Indies. Abdomen green, with rufous rings; fize moderate.

Scabiosus. Thorax fquare, warty, and black, the whole margin yellow; wing-cafes green, dotted with yellow. Fabr.

Native of Tranquebar, in the cabinet of Sehreftedt. The fize of the laft; antennæ black; head black, with a broad yellow crown, reaching on the fides to the edge of the thorax; body black, with the edges of the fegments red; breaft fpotted with red.

Squarrosus. Thorax fomewhat three-jointed, the divifions fpinous each fide; wings red, dotted with black. Fabr. *Gryllus fquarrofus*, Linn. Mant. Inf.

An African fpecies, figured by Drury. The head and thorax dull green; wing-cafes green, fpotted with brown.

Hæmatopus. Thorax fomewhat carinated and warty; head obtufe; thighs ciliated with hairs. Linn. *Acrydium rubripes*, Degeer.

Native of India. Wing-cafes cinereous; wings hyaline, reticulated with black veins.

Flavicornis. Thorax fomewhat carinated, and green; wing-cafes immaculate; wings at the bafe rufous; pofterior fhanks fanguineous, ferrated with yellow. Fabr. Donov. Inf. China.

A large fpecies, very abundant in China. The antennæ are yellow; abdomen greenifh with dufky rings, and the legs green.

Flavescens. Thorax fomewhat carinated, and greyifh; wings yellowifh at the bafe, with an abbreviated band at the tip, and dots brown. Fabr.

Inhabits Tranquebar; in fize correfponds with the laft; head and thorax with yellowifh lineations; wing-cafes grey, or varied with cinereous and brown; pofterior fhanks fpinous, red, and black at the tip.

Pictus. Wing-cafes green, dotted with white, and reddifh at the tip; body variegated with blue and yellow Fabr.

Native of South America.

Tartaricus. Thorax with three fegments; front impreffed; mandibles the colour of the body. Linn.

Wing-cafes pale greyifh, fpotted with brown. Inhabits Africa.

Migratorius. Thorax fomewhat carinated, of one fegment, mandibles blue. Linn.

The migratory locuft is a native of Tartary, from the eaftern parts of which it fometimes emigrates over the adjacent countries in fuch immenfe legions, as to occafion the moft incredible mifchief. Thefe hofts of depredators are oftentimes fo numerous, as to darken the air at noon-day in their flights. Wherever they fettle, the moft fertile regions are, in a few days, rendered defolate; and the very putrefaction arifing from the number of their dead, becomes the fource of peftilence to man and animals. It is feldom, except in eaftern countries, that thefe calamities are experienced to fuch a dreadful extent, though they fometimes are, as the vifitation of the locuft in Europe, about the middle of the eighteenth century, very clearly proves. The ravages committed by locufts in the fouth of Europe, about the period laft mentioned, are deferibed at great length by Roefel, from which the more material part of the curious information on that fubject, detailed in the 46th volume of the Tranfactions of the Royal Society, feems to be felected. This account relates to the myriads of locufts that over-ran Walachia, Moldavia, Tranfylvania, Hungary, and Poland, in 1747 and 1748, and which, being recorded by an eye-witnefs of unqueftionable accuracy, explains the hiftory of that deftructive creature in a fatisfactory manner: the following is the fubftance of the obfervations alluded to:

The

The firſt ſwarms of the locuſts entered Tranſylvania in Auguſt, 1747: theſe were ſucceeded by others, which were ſo ſurpriſingly numerous, that when they reached the fortification called the Red Tower, they were full four hours in their paſſage over that place; and they flew ſo cloſe, that they made a ſort of noiſe in the air by the beating of their wings againſt one another. The width of the ſwarm was ſome hundreds of fathoms, and its height or denſity ſo conſiderable, as to hide the ſun, and darken the ſky to that degree when they flew low, that people could not know one another at the diſtance of twenty paces. Arriving at the river that runs through the vallies of the Red Tower, they could neither find reſting place nor food, and being at length tired with their flight, one part of them ſettled on the unripe corn on the hither ſide of the Red Tower, ſuch as the millet and Turkiſh wheat, &c. and the other pitched on a low wood, where, having miſerably waſted the produce of the land, they continued their journey, as if a ſignal had actually been given for a march.

The guards of the Red Tower attempted to ſtop their irruption into Tranſylvania, by firing at them; and indeed, where the balls and ſhot ſwept through the ſwarm, they gave way and divided, but having filled up their ranks in a moment, they proceeded on their journey. In the month of September, ſome troops of them were thrown to the ground by great rains and other inclemency of the weather, and thoroughly ſoaked with wet, they crept along in queſt of holes in the earth, dung, and ſtraw; where, being ſheltered from the rains, they laid a vaſt number of eggs, which ſtuck together by a viſcid juice, and were longer and ſmaller than what is commonly called an ant's egg, or very like grains of oats. The females, having laid their eggs, die, like the ſilkworm. When they entered the fields of Tranſylvania, they did not ſeem to intend remaining there, but were thrown to the ground by the force of the wind, and there laid their eggs, a vaſt number of which being turned up and cruſhed by the plough, in the beginning of the enſuing ſpring, yielded a yellowiſh juice. In the ſpring of 1748, certain little blackiſh worms were ſeen lying in the fields, and among the buſhes, ſticking together and collected in cluſters, not unlike the hillocks of moles or ants. As nobody knew what they were, ſo there was little or no notice taken of them, and in May they were covered by the ſhooting of the corn ſown in winter; but the ſubſequent June diſcovered what theſe worms were; for then, as the corn ſown in ſpring was pretty high, theſe creatures began to ſpread over the fields, and became deſtructive to the vegetables by their numbers. Then, at length, the country-people, who had ſlighted the warning given to them, began to repent of their negligence; for as theſe inſects were now diſperſed all over the fields, they could not be extirpated without injuring the corn. At that time they differed very little from our common graſshoppers, having their head, ſides, and back of a dark colour, with a yellow belly, and the reſt of a reddiſh hue. About the middle of June they were generally a finger's length, but their ſhape and colour continued as before. Towards the end of June they caſt off their outward covering, and then it plainly appeared they had wings, but as yet unripe, and unexpanded, the body being alſo tender and of a yellowiſh green: then, in order to render themſelves fit for flying, they gradually unfolded their wings with their hinder feet, and as ſoon as any of them found themſelves able to uſe their wings they ſoared up, and by flying round the others, enticed them to do the ſame; and thus their numbers increaſed daily: they took flights in a circular manner of twenty or thirty yards ſquare, until they were joined by the reſt; and after miſerably laying waſte their native fields, they proceeded elſewhere in large troops. Wherever theſe bodies of locuſts happened to pitch, they ſpared no ſort of vegetables: they eat up the young corn, and the very graſs: but nothing was more diſmal than to behold the lands in which they were hatched; for they ſo greedily devoured every trace of herbage before they could fly, that they left the ground quite bare. There is nothing to be feared in thoſe places to which this plague did not reach before the autumn; for the locuſts have not ſtrength to fly to any conſiderable diſtance but in the months of July, Auguſt, and the beginning of September; and even then, in changing their places of reſidence, they ſeem to tend to warmer climates.

Different methods are to be employed according to the age and ſtate of theſe inſects for their deſtruction. Some will be effectual as ſoon as they are hatched; others when they begin to crawl, and others when their wings appear. Experience teaches us, that it is of great ſervice to ſeek out the places where the females had lodged, about March and April, and to deſtroy their eggs, or little worms, with ſticks or briars. In the ſummer, when they have invaded the corn-fields, it is almoſt impoſſible to extirpate them without thoroughly threſhing the whole piece of land that harbours them with ſticks and flails, and thus cruſhing the locuſt with the produce of the land. Finally, when the corn is ripe, or nearly ſo, there is no other method of getting rid of them but to ſurround the piece of ground with a multitude of people, who may fright them away with bells, braſs veſſels, and all other ſorts of noiſe. But this will not ſucceed till the ſun is pretty high, ſo as to dry the corn from the dew; for otherwiſe they will either ſtick to the ſtalks, or lie hid under the graſs; but when they happen to be driven to a waſte piece of ground, they are to be beat with ſticks or briars; and if they gather together in heaps, ſtraw or litter may be thrown over them and ſet on fire. It will be likewiſe of uſe, where a large troop of them has pitched, to dig a long trench of an ell wide, and the ſame in depth, and place ſeveral perſons along the edges, provided with brooms and ſuch like things, while a number of people form a ſemicircle that takes in both ends of the trench, and encompaſſes the locuſts, and by making the noiſe above-mentioned drive them into the trench, out of which, if they attempt to eſcape, thoſe on the edges are to ſweep them back, and then cruſh them with their brooms and ſtakes, and bury them, by throwing in earth upon them. But when they begin to fly there ſhould be horſemen upon the watch in the fields, who, upon any appearance of the ſwarm taking wing, ſhould immediately alarm the neighbourhood by a certain ſignal, that they might come and frighten them away by all ſorts of noiſe, and if tired with flying they happen to pitch on a waſte piece of ground, it will be very eaſy to kill them with ſticks and brooms in the evening or early in the morning, while they are wet with dew, or any time of the day in rainy weather, for then they are unable to fly.

The devaſtations of locuſts in various parts of the world, at different periods, are recorded by many writers, ſome examples of which are very remarkable. Thus in the year 593 of the Chriſtian era, after a great drought, theſe animals appeared in ſuch vaſt legions as to cauſe a famine in many countries. In 677 Syria and Meſopotamia were overrun by them. In 852 immenſe ſwarms took their flight from the eaſtern regions into the Weſt, flying with ſuch a ſound, that they might have been miſtaken for birds: they deſtroyed all vegetables, not ſparing even the bark of trees, and the thatch of houſes; and devouring the corn ſo rapidly as to deſtroy, on computation, an hundred and forty acres in a day: their daily marches or diſtances of flight were computed

puted

puted at twenty miles; and theſe were regulated by leaders or kings, who flew firſt, and ſettled on the ſpot which was to be viſited at the ſame hour the next day by the whole legion: the marches were always undertaken at ſun-riſe. Theſe locuſts were at length driven by the force of the winds into the Belgic ocean, and being thrown back by the tide and left on the ſhore, cauſed a dreadful peſtilence by their ſmell. In 1271 all the corn-fields of Milan were deſtroyed; and in 1339 all thoſe of Lombardy. In 1541 incredible hoſts afflicted Poland, Walachia, and all the adjoining territories, darkening the ſun with their numbers, and ſpreading deſolation throughout the land.

The evidence of hiſtory aſſures us, that Britain has been occaſionally ſubject to the viſitation of the locuſts; yet it has never, we apprehend, appeared here in numbers ſufficiently formidable to commit great depredation. From the Philoſophical Tranſactions we learn, that in the year 1693 ſome ſwarms of locuſts (probably of this ſpecies) ſettled in Wales; two vaſt flights of which were obſerved in the air, not far from the town of Dol-ghelly, in Merionethſhire, and many about the ſame time fell in South Wales, in the county of Pembroke. The ſpecies that viſited this country in the year 1748, (and of which ſome ſmall flocks were ſeen in the environs of London,) was certainly of this kind, as appears from the teſtimony of Mr. G. Edwards, whoſe work on birds contains a repreſentation of the inſect in queſtion, under the name of the great brown locuſt. We are not aware that the locuſt appeared again in Britain after that period till within about the laſt ten years, when its exiſtence at leaſt, in this country, was again diſtinctly aſcertained, as an example of this deſtructive creature in a living ſtate came at that time under our own inſpection. The particulars relative to the capture of the laſt mentioned inſect are recorded in the "Natural Hiſtory of Britiſh Inſects," and as this affords, we apprehend, the lateſt teſtimony of the ſpecies being obſerved at large in England, the following extract from that publication may not be conſidered altogether unacceptable, or devoid of curious information: "In the month of September 1799, lady Aylesford moſt obligingly communicated a living ſpecimen of the migratory locuſt, (Gryllus migratorius,) and we deem ourſelves peculiarly fortunate in the opportunity it affords us to aſcertain the difference, however inconſiderable, that prevails between the variety found in England, and thoſe of warmer climates. It is repreſented for this reaſon both in a reſting poſition, and with the wings expanded. This ſpecimen was found in a barley field near Packington in Warwickſhire. It lived ſeveral days after its arrival in London, and would probably have ſurvived much longer had it not been injured in the journey, and weakened by long confinement. We remarked, that, in feeding, it cut the ſtalk of the graſs, or other tender plants on which it ſubſiſts, aſunder in the middle, or near the root, and tearing off the leaves eat only the pith: this may, therefore, in ſome meaſure account for the great miſchief and depredation theſe inſects commit, when they ſettle in vaſt numbers on any tract of cultivated land." Donov. Br. Inſ. v. viii.

Ruficornis. Thorax black on the back; keel yellow; antennæ and ſhanks yellow. Fabr.

Native of Sierra Leona; and rather leſs than the former. The antennæ reddiſh; wing-caſes varied with brown and cinereous.

Lineola. Thorax ſomewhat carinated and fuſcous, with a rufous dorſal line; poſterior thighs ſanguineous within; ſhanks blueiſh. Fabr.

An Italian ſpecies, the ſize of G. migratorius, deſcribed by Fabricius from a ſpecimen in the cabinet of Dr. Allioni.

Variegatus. Thorax lineated with yellow; wing-caſes green; wings blue. Linn.

Native of America. Antennæ black with red rings; front red with black dots.

Vocans. Thorax carinated; wing-caſes pale with ocellar brown ſpots; wings ferruginous at the baſe. Fabr.

Head pale brown; mandibles black; thorax ferruginous with yellow margin; wing-caſes rounded. Inhabits New Holland.

Luridus. Thorax ſub-carinated and black; ſpot on the breaſt, and belts on the abdomen, ſanguineous; front projecting. Fabr.

Native of Africa. The antennæ black, with the laſt joint but one yellowiſh; head black; front above the antennæ advanced, obtuſe, and flat; thorax rough and immaculate; legs black.

Nervosus. Greeniſh; thorax black on the back with a yellow line; wing-caſes greeniſh, with a yellowiſh, or ſanguineous ſub-marginal nerve. Fabr.

Leſs than gryllus migratorius; the antennæ ſhort, yellow, or ferruginous; head greeniſh, furrowed each ſide; body green; poſterior ſhanks dentated, the teeth white, at the tip ferruginous. Inhabits Guinea.

Musicus. Thorax carinated; wing-caſes anteriorly black, with a white band; behind grey, varied with black. Fabr.

Native of New Holland.

Tuberculatus. Thorax ſcabrous; wings red, with cinereous tip; poſterior thighs above and beneath carinated. Fabr.

Found in ſandy places in Jutland.

Cisti. Thorax ſcabrous; creſt bifid; wings red, with a black band; poſterior thighs canaliculated. Fabr.

Diſcovered by Vahl on the ciſtus hamifolius.

Stridulus. Thorax carinated; wings red, with the tip black. Linn.

Inhabits ſandy places in Europe.

Morio. Obſcure; thorax ſub-carinated; wings black and immaculate. Fabr.

Native of Africa.

Ferrugineus. Thorax tuberculated; wing-caſes duſky and immaculate; wings ferruginous; head pointed. Fabr.

An African ſpecies. The antennæ are black, with two yellow rings; mouth brown, with red ſpots; body annulated with brown and yellow; thighs beneath, and all the ſhanks rufous.

Surinamus. Thorax with four yellow lines; wings blue; wing-caſes fuſcous. Linn.

Native of South America.

Italicus. Fuſcous; thorax carinated; wings red, with the tip hyaline. Linn.

Inhabits the ſouth of Europe.

Germanicus. Teſtaceous; wings ſanguineous, with hyaline tip; poſterior thighs dotted with black. Roeſ. &c.

Found in Germany. The thorax is ſub-carinated; ſhanks of the hind-legs ſanguineous.

Thalassinus. Thorax ſmooth and green; wings hyaline, inner ſide green, with the tip brown. Fabr.

Native of Italy.

Virginianus. Thorax carinated; wing-caſes with a green-rib; wings black, with the baſe greeniſh. Fabr.

A ſmall ſpecies, found in North America. Thorax and wing-caſes dull rufous.

Cerulans. Thorax ſmoothiſh; wing-caſes pale, ſpotted black; wings blueiſh on the thinner edge. Linn.

An European ſpecies.

Carolinus. Thorax ſub-carinated; wings black; the poſterior margin cinereous. Linn.

Native of North America.

Obscurus. Thorax ſmooth; wings red in the diſk, with black band and hyaline tip. Linn.

Inhabits ſandy places in Africa.

Fasciatus. Thorax unequal; wings at the baſe red, the tip hyaline, with fuſcous ſpots. Fabr.

A ſmall ſpecies, found in France; the antennæ ſhort, fuſcous, with the tip darkeſt; head duſky, with an impreſſed line in the middle.

Sibiricus. Thorax ſub-carinated; antennæ clavated; anterior ſhanks ovate-clavated. Linn. *Gryllus clavimanus*, Pallas.

Native of Siberia.

Cærulescens. Thorax ſub-carinated; wings greeniſh-blue, with a black band. Linn.

An inhabitant of the ſouth of Europe.

Cinerascens. Thorax carinated; wing-caſes green on the thinner margin; wings yellowiſh at the baſe, at the tip cinereous. Fabr.

Front greeniſh; mouth ferruginous; wing-caſes dotted with white. Native of Italy.

Sulphureus. Duſky; thorax carinated; wings bright yellow, with blackiſh tip. Fabr.

A ſmall ſpecies, found in America. The head, thorax, and wing-caſes dull ferruginous; poſterior thighs annulated with yellow and black within; ſhanks blue, and paler at the baſe.

Flavus. Thorax carinated; wings yellow, with black band, the tip cinereous. Linn.

Native of America. Antennæ ſhort and yellowiſh; wing-caſes brown, with a whitiſh band or two at the baſe; poſterior ſhanks ſanguineous.

Cyanipes. Brown, with a yellow dorſal line; poſterior ſhanks yellow, tipped with blue. Fabr.

Inhabits America.

Rusticus. Grey; wing-caſes brown, at the baſe ſpotted with yellow, the tip varied with cinereous and brown. Fabr.

Thorax generally with a yellow dorſal line, and black lateral ſpots; wings cinereous, reticulated with brown. Native of America.

Lateralis. Thorax brown, with a yellow margin, and dot each ſide; ſhanks yellow. Fabr.

Inhabits America.

Velox. Thorax flat; body brown; margin of the thorax and legs greeniſh. Fabr. Donov. Inſ. China.

A ſmall ſpecies, found in China.

Biguttulus. Thorax carinated; wing-caſes clouded, with an oblong white dot near the tip. Linn. Donov. Brit. Inſ.

Native of Britain and the more northern parts of Europe, frequenting ſandy plains.

Viridulus. Thorax carinated; body above green; margin of the wing-caſes whitiſh. Linn. Donov. Brit. Inſ.

Frequent in ſandy places in Britain, Sweden, and Germany.

Grossus. Thighs ſanguineous; wing-caſes greeniſh; antennæ cylindrical. Linn. *Acrydium rubripes*, Degeer.

An European ſpecies.

Captivus. Thorax cruciate; body brown; poſterior thighs and ſhanks with a white band. Fabr.

Native of New Holland.

Clavicornis. Greeniſh, with a black lateral ſtripe; antennæ clavated. Fabr.

A ſmall ſpecies, found in Surinam.

Rufus. Fuſcous, with rufous abdomen; antennæ ſub-clavated. Linn.

Inhabits ſandy places in Europe.

Pedestris. Body fleſh-coloured and apterous. Linn. *Acrydium apterum*, Degeer.

Native of Europe and Siberia.

Perspicillatus. Rudiments of the wings with an ocellar black ſpot; eyes golden. Linn.

Inhabits India, and is probably only the larva of ſome other ſpecies.

Obscurus. Duſky, with a yellow dorſal line. Fabr. Suppl.

Size of G. nervoſus, and inhabits North America. The thorax is rough, behind rounded; wings duſky; legs greeniſh; the poſterior ſhanks armed with yellow ſpines with black tips.

Muricatus. Thorax thorny; creſt behind armed with two teeth; wings cinereous, with black band. Fabr. Suppl. Pallas.

Deſcribed as an inhabitant of the ſouth of Ruſſia, in ſize and appearance reſembling gryllus ſtridulus.

Sanguinipes. Greeniſh; thorax on the back, and wing-caſes fuſcous; ſhanks ſanguineous. Fabr. Suppl.

Size of the laſt, and inhabits North America. The antennæ are ferruginous with the tip black; ſtripe of brown on the thorax broad; abdomen greeniſh; teeth on the poſterior ſhanks blank.

Tamulus. Fuſcous; wing-caſes at the baſe and marginal line green, tip hyaline, and ſpotted; poſterior legs variegated. Fabr. Suppl.

Native of India; ſize of the laſt; wings fuſcous with yellowiſh baſe; poſterior thighs without fuſcous, with white tip; within varied with white rings, rufous, and black.

Ciliatus. Thorax carinated and duſky; wings ſanguineous; poſterior thighs ciliated. Fabr. Suppl.

A ſmall ſpecies found in India. The head is fuſcous, the front ſcarcely prominent; wing-caſes teſtaceous and immaculate.

Scaber. Rough, fuſcous, with abbreviated wing-caſes. Fabr. Suppl.

Native of the Eaſt Indies; wing-caſes ſhorter than the body.

Genus Pneumora.

Antennæ ſhort and cylindrical; head ſmall, inflected, and armed with jaws; thorax convex, and carinated beneath; body ovate, inflated and diaphanous; wing-caſes membranaceous, and deflected; legs formed for running.

The inſects of this genus appear like a hollow inflated membrane or bladder, and are nearly as tranſparent; they emit a ſhrill noiſe morning and evening by rubbing, as it is imagined, their ſerrated legs together. The ſpecies of this remarkable genus, amounting to three in number, are natives of the Cape of Good Hope, and were firſt made known to the world by profeſſor Thunberg in the Tranſactions of the Swediſh Academy.

Species.

Immaculata. Green ſpotted with white; wing-caſes immaculate. Thunb.

Head green; orbits white; three red ſhining dots between the eyes, and above theſe two ſhort denticles; antennæ green; thorax rough with a ſhort tooth before, and an impreſſed wrinkle in the middle; wing-caſes grey, reticulated with green.

Maculata. Wing-cafes green, with quadrangular white fpots. Thunb.

The antennæ in this fpecies are reddifh; wing-cafes reticulated with white dots.

6-Guttata. Wing-cafes green, with two white fpots; abdomen with three white fpots each fide. Thunb.

Large; antennæ green, with two denticles each fide under the antennæ; thorax green with white margin, and two denticles before, one in the margin, the other before the middle; in the middle a deep ridge.

Genus Truxalis.

Antennæ fomewhat prifm-fhaped or enfiform, and inferted above the eyes; head pyramidal or conic, and longer than the thorax; body elongated; no fcutel; wing-cafes membranaceous, flexile, and as long as the body; legs fhort; pofterior pair elongated; tarfi on the fore feet with three joints, pofterior ones, with four.

Species.

Nasutus. Head conic; body green. Linn. *β Gryllus turritus*, Linn. Donov. Inf. China.

Inhabits China, and thence extends to Africa. The mouth is placed at the bafe of the head, the antennæ at the tip; wings hyaline, greenifh towards the bafe. This is the largeft of its family, and is about four or five inches in length.

Conicus. Head conic; body fufcous; half the rib of the wing-cafes green, with a line of white dots. Fabr. Donov. Inf. New Holland.

The antennæ are brown and longer than the thorax; head brown, the fides green at the bafe.

Vittatus. Head prominent; body teftaceous; head, thorax, and pofterior thighs with a lateral filvery ftripe. Fabr. Donov. Inf. China.

Antennæ teftaceous; a blueifh fillet, and line of filvery dots on the pofterior thighs; length about two inches.

Hungaricus. Head conic, and green; antennæ and legs teftaceous. Herbft.

A fpecies of middle fize, found in Hungary.

Brevicornis Head prominent and green; antennæ compreffed, and the length of the thorax. Linn.

Native of America.

Crenulatus. Head prominent and green, with the inner margin rofy. Fabr.

Inhabits Tranquebar.

Genus Acrydium.

Antennæ filiform, and inferted under the eyes; feelers filiform and equal; lip ovate and cleft at the tip; head ovate and inferted; thorax carinated; fcutel produced behind to the end of the abdomen, and covering the wings; wing-cafes none; legs fhort, pofterior pair long, formed for leaping, the tarfi confifting of three joints.

Morbillosum. Scutel flat, pointed, and as long as the abdomen. Fabr.

Native of Sierra Leona. The body dufky; thorax carinated; legs blackifh; pofterior thighs compreffed and carinated.

Bipunctatum. Dark brown; fcutel as long as the abdomen. Geoff.

Inhabits fandy places in Europe.

Subulatum. Dark brown; fcutel longer than the abdomen. Geoff. Donov. Brit. Inf.

Native of Britain, and other parts of Europe.

Bifasciatum. Brown fpotted with white, with two lateral ochraceous bands. Herbft.

Inhabits Berlin.

Bimaculatum. Thorax brown with an ochraceous lunule each fide. Herbft.

Inhabits Berlin.

Granulatum. Varied with grey, green, and blackifh; rough with raifed dots and flattened at the fides; thorax fub-oval and gibbous. Herbft.

Inhabits Berlin.

Binotatum. Grey; a ferruginous fpot each fide the fcutel towards the tip of the lamina of the wings. Gmel.

Gryllus, in *Ichthyology*, a name given by fome to the *conger*, or fea-eel. Ritterfhufius, who has given commentaries on Oppian's Halieutics, has given this word as the tranflation of the gongros of that author, which is the name of the fame fifh with the congrus of Ariftotle, and the other ancient Greeks. Artedi has avoided the occafion of any fuch errors for the future, by not allowing it any generical name at all. He makes it a fpecies of his genus of *muræna*, and diftinguifhes it from all the others by the name of the *muræna* with the rim of the back-fin black.

Gryllus *Vulgaris*, a name given by Gefner, Bellonius, and others, to the *ophidion* of the generality of authors; diftinguifhed by Artedi by the name of the *ophidion* with four cirri, or beards, at the lower jaw. Pliny has mentioned this under the name of the *pifciculus congro fimilis*.

GRYNÆUS, Simon, in *Biography*, fon of a Suabian farmer, was born at Veringen in the year 1493. He difcovered an early inclination to learning, and was fent to fchool at Pfortfheim, at which he had the celebrated Melancthon for a fellow ftudent, with whom he contracted an intimacy and friendfhip that lafted during life. From Pfortfheim he went for improvement to Vienna, where he was admitted to the degree of mafter in philofophy, and afterwards appointed to the profefforfhip of the Greek language. Soon after this he embraced the Proteftant religion, and was on that account expofed to the perfecutions of the Catholics, particularly at Buda, where he was thrown into prifon. He was much beloved by the Hungarian nobility, at whofe interceffion he obtained his liberty, and retired to Wittemberg, where he found Luther and Melancthon, and held repeated conferences with them on religious and other topics. In 1523 he was appointed Greek profeffor at Heidelberg, the duties of which office he performed till 1529, when, at the perfuafion of Œcolampadius, he undertook the profefforfhip at the univerfity of Bafil. In 1531 he took a journey to England, where, with the recommendations of Erafmus, he was kindly received by the lord chancellor, fir Thomas More, who, notwithftanding his principles, took him into his houfe, and made him his conftant companion. He likewife moft liberally defrayed his expences, and fent him to Oxford, with fuch powerful recommendations to the heads of the univerfity, that he had free acceſs to all the public libraries, which was the principal object of his miffion to this country. Before he left England he was prefented by fir Thomas More with fome MSS. of Proclus. In 1536 he returned to Bafil, juft in time to witnefs the laft moments of his excellent friend, the illuftrious Erafmus. He died of the plague at Bafil in the year 1541. His focial virtues, and his piety towards God, were as highly refpected, as his great acquirements as a fcholar. He was the firft perfon who publifhed the "Almageft" of Ptolemy, in Greek, to which he added a preface concerning the ufe to be made of the author's doctrine. He was likewife the editor of "Euclid," "The Works of Plato," with fome "Commentaries of Proclus." He was author of the "Life of Œcolampadius."

GRYNAU, in *Geography*, a town of Switzerland, in the

the canton of Glarus, on the Linth, where it empties itſelf into the lake of Zurich, with a harbour for boats.

GRYPHITES, a name given by Luid to a ſpecies of foſſil bivalve ſhells, which are referred by Linnæus to *anomia*, and by Bruguière to *oſtrea*. They have obtained the name gryphites from a ſuppoſed reſemblance to the bill of a fabulous bird; but may, perhaps, be more aptly compared to an ancient bark with high and curved ſtern. (See SHELLS, *Foſſil.*)

Theſe ſhells, of different ſizes, ſeem to have a place in four different parts of the Britiſh ſeries of ſtrata, *viz.* 1ſt. In the clunch clay, immediately below the Woburn ſand, mixed with belemnites: ſome of theſe gryphites are very large, and great numbers of them have been perforated partly or wholly through, apparently by ſome fiſh having the habits of the pholas (ſee Phil. Mag. vol. xxxv. p. 259).

2d. In the Bedford lime-ſtone, ſmaller than the above: of this ſtone, a bolder, containing a gryphites, was found in that remarkable aſſemblage of bolders and gravel, on Bladon hill in Newton-Solney, in Derbyſhire.

3d. In one of the ſtrata of lime-ſtone near Bath; a figure of this ſhell is given in Walcott's "Petrifactions found near Bath," *fig.* 34, pages 25 and 51.

4th. In blue clay at Cheltenham, with belemnites: which perhaps may, however, be alluvial or moved.

The gypſum quarries at Chellarton, S. of Derby, are covered by a conſiderable thickneſs of alluvial clay, among whoſe numerous ſtones and foſſils many gryphites, apparently from the clunch clay, are found; and doubtleſs it was from hence that the ſpecimen came, which the late Mr. William Martin mentions, p. 14. of the ſyſtematic arrangement at the end of his "Petrificata Derbienſia," vol. i., and not from any of the Derbyſhire ſtrata.

GRYPHIUS, CHRISTIAN, in *Biography*, born in Sileſia in the year 1649, was ſon of Andrew, a celebrated German dramatic writer. In 1674 Chriſtan became profeſſor of eloquence at Breſlau, and was made, in 1686, principal and profeſſor of the Magdalen college in the ſame city, and afterwards librarian. He was a man of extenſive erudition, and was very learned in the modern and ancient languages. He died in 1705, having, juſt before he expired, cauſed to be performed, in his chamber, a piece of poetry of his own, ſet to muſic, expreſſive of the conſolation received by the dying, from meditating on the death of Chriſt. He was author of "Poems in German;" "A Hiſtory of the Orders of Knighthood;" "A Treatiſe on the Origin and Progreſs of the German Language;" "Diſſertatio de Scriptoribus, Hiſtoriam Sæculi xvii. illuſtrantibus."

GRYPHIUS, SEBASTIAN, a learned printer, was a native of Reutlingen, in Suabia, but he exerciſed his profeſſion at Lyons, and obtained great reputation for the beauty and accuracy of his works. He was very converſant in the learned languages, and employed men of erudition as his correctors. Julius Scaliger, and Conrad Geſner thought highly of his talents. One of his fineſt works is a Latin bible, in two volumes folio, printed in very large types. He died in 1556, at the age of about ſixty-three.

GRYPHIUS *Pes*, the *griffon's claw*, a name of a chirurgical inſtrument deſcribed by Ambroſe Pare, and uſed for extracting moles from the uterus.

GRYPHUS, in *Surgery*, a ſort of crooked pincers uſed by ſurgeons.

GRYPHUS, or *Griphus*, is alſo a kind of enigma, or an artful obſcure deſcription of a thing.

The word γρῦφος ſignifies a net, and accordingly was the name given to certain enigmatical queſtions which were ſportively propoſed during an entertainment, and which the gueſts were frequently puzzled to unravel. Thoſe who were unable to anſwer them were ſubjected to a forfeit. Of theſe gryphi there were different kinds. Some were properly ænigmas: ſuch is the following: "I am very large at my birth, and likewiſe in old age; but very ſmall when at maturity." *A ſhadow.* Such is alſo this: "There are two ſiſters, who inceſſantly beget each other." *Day* and *Night*, both which words are feminine in the Greek. Other gryphi turn on the reſemblance of names; *e.g.* "What is that which is at once found on the earth, in the ſea, and in the heavens?" The *dog*, the *ſerpent*, the *bear*. The names of theſe animals have been given to certain conſtellations. Others were formed by a play on letters, ſyllables, or words. Travels of Anacharſis, vol. vii. p. 116, 8vo.

GRYPOSIS, an incurvation of the nails. The word is derived from γρυπόω, *to incurvate.*

GRYS, in *Geography*, a river of America, which runs into lake Erie. N. lat. 41° 45'. W. long. 82° 2'.

GRYSINGARDE, a town of Norway, in the dioceſe of Drontheim; 76 miles S.E. of Drontheim.

GRYSON, a new county of Virginia, taken from Montgomery, which bounds it on the N. It has the ſtate of N. Carolina S., of Henry and Wythe counties on the E. and W.

GRYTSKAR, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 62° 33'. E. long. 20° 53'.

G-SOL-RE-UT, the name of the eighth note, octave to gammut, in the ſcale of Guido. See GAMMUT, SCALE, and GUIDO.

GSUVIE, a town of Arabia Felix; 16 miles S. of Loheia.

GUA, a town of the iſland of Cuba; 36 miles S.W. of Bayamo.

GUA *Suba*, a river of Bengal, which runs into the bay. N. lat. 21° 25'. E. long. 89° 8'.

GUACA, a town of South America, in the province of Quito; 70 miles N.N.E. of Quito.

GUACAGUACU, in *Ornithology*, the Braſilian name of a bird of the larus, or gull kind, the LARUS *hibernus*; which ſee.

GUACAPA, in *Geography*, a town of Mexico; 70 miles E.S.E. of Guatimala.—Alſo, a river of Mexico, in Nicaragua, which runs into the Pacific ocean.

GUACARA, a town of S. America, in the province of Caraccas; 65 miles S.W. of Leon de Caraccas.

GUACARI, in *Ichthyology*. See LORICARIA *Plecoſtomus*.

GUACATARA, in *Geography*, a town of S. America, in the province of Tucuman, chiefly inhabited by Indians, under the juriſdiction of an Indian magiſtrate; 50 miles N. of St. Salvador de Jugai.

GUACHIAYACHU, a town of S. America, in the audience of Quito; 60 miles E.S.E. of Macas.

GUACHO, a ſea-port of Peru, in the audience of Lima, between the iſland of St Martin and Callao.

GUACHUCO, a town of New Mexico, in New Navarre.

GUACOCINCA, a town of Mexico, in the province of Tlaſcala, containing about 600 inhabitants, of whom about 100 are Spaniards.

GUACOTITLAN, a town of Mexico, in New Biſcay; 80 miles S. of Parral.

GUACUCUJA, in *Ichthyology*, the name of a very remarkable Braſilian fiſh, called alſo by ſome the *veſpertilio aquaticus*, or water-bat. See LOPHIUS *veſpertilio.*

GUADAGNI, GAETANO, in *Biography*, a native of Vicenza, one of the moſt celebrated opera ſingers of the laſt century.

But his ſinging was not more admired than his figure, dignity, grace, and intelligence, as an actor.

He firſt came into England with a company of burletta ſingers, brought hither by Croza, an adventurous impreſario, in 1748, at which time there was no ſerious opera in meditation.

It was the firſt company of comic ſingers that tried its fortune in London. Guadagni, then very young, wild, and idle, with a very fine counter-tenor voice of only ſix or ſeven notes compaſs, performed the ſerious man's part in theſe burlettas, and was but little noticed by the public; till Handel, pleaſed with his clear, ſweet, and full voice, engaged him to ſing, in Samſon and the Meſſiah, the fine airs which he had compoſed for Mrs. Cibber's ſweet and affecting voice of low pitch: ſuch as, "He ſhall feed his flock like a ſhepherd;" "Return O God of Hoſts;" and "He was deſpiſed and rejected," &c.

Ciampi was then the opera compoſer, who, beſides burlettas, furniſhed ſeveral ſerious operas, in which Guadagni had the firſt man's part, and Fraſi that of firſt woman; but both being regarded only as ſecond-rate ſingers, the ſucceſs of theſe dramas was neither flattering to the compoſer nor the ſingers; and the profits to the impreſario, ſig. Croza, were ſo inconſiderable, that *one fine morning* he decamped juſt time enough to eſcape impriſonment, after ſweeping the treaſury of the opera-houſe, and leaving actors, trades-people, and all perſons connected with the theatre at the mercy of the bailiffs, whoſe ſearch he had had the addreſs to elude, in ſpite of an advertiſement, which appeared in the Daily Advertiſer, May 15th 1750, ſigned Henry Gibbs, a tea-merchant, in Covent-garden, offering a reward of 30*l.* to any one who would ſecure his perſon. This event put an end to operas of all kinds, for ſome time.

However, though the opera-houſe was ſhut up, Guadagni remained in England, ſinging for Handel, and in ſummer at the triennial meeting, in oratorios under the direction of Mr. Harris in Saliſbury cathedral, &c. and laſtly at Drury-lane with Fraſi in the Engliſh opera of the "Fairies," ſet to muſic by the late Mr. Smith, the aſſiſtant and ſucceſſor of Handel in carrying on oratorios. This opera, written by Garrick on the plan of Shakeſpear's Midſummer Night's Dream, had conſiderable ſucceſs. In 1753, when the run of this muſical drama was over, Guadagni returned to Italy, where he remained till 1754, when he went to Liſbon as ſecond man, under Gizziello, and, in 1755, very narrowly eſcaped deſtruction during the earthquake. After this dreadful calamity, Gizziello, ſeized with a fit of devotion, retired into a monaſtery, where he ſpent the reſt of his life. Having a friendſhip for Guadagni, and being pleaſed with his voice and quickneſs of parts, he perſuaded the young ſinger to accompany him in his retreat, where, during a conſiderable time, he took great pains in directing his ſtudies; and it is from this period that Guadagni's great reputation, as a refined and judicious ſinger, may be dated. His ideas of acting were taken much earlier from Garrick, who, when he performed in an Engliſh opera called the Fairies, took as much pleaſure in forming him as an actor, as Gizziello did afterwards in poliſhing his ſtyle of ſinging. After quitting Portugal, he acquired great reputation as firſt man in all the principal theatres in Italy, and the year before his return to England, he excited great admiration by his talents, as well as diſturbance by his caprice, at Vienna. The higheſt expectations of his abilities were raiſed by rumour before his arrival here for the winter ſeaſon; and as an actor, he ſeems to have had no equal on any ſtage in Europe: his figure was uncommonly elegant and noble; his countenance replete with beauty, intelligence, and dignity; and his attitudes and geſtures were ſo full of grace and propriety, that they would have been excellent ſtudies for a ſtatuary. But though his manner of ſinging was perfectly delicate, poliſhed, and refined, his voice ſeemed, at firſt, to diſappoint every hearer. Thoſe who remembered it when he was in England before, found it comparatively thin and feeble. For he had now changed it to a ſoprano, and extended its compaſs from ſix or ſeven notes, to fourteen or fifteen. And let a fluid of ſix feet in depth be ſpread over more than double its uſual ſurface, and it will neceſſarily be ſhallower, though of greater extent. The muſic he ſung was the moſt ſimple imaginable; a few notes with frequent pauſes, and opportunities of being liberated from the compoſer and the band, were all he wanted. And in theſe ſeemingly extemporaneous effuſions, he proved the inherent power of melody totally divorced from harmony, and unaſſiſted even by uniſonous accompaniment. Surpriſed at ſuch great effects from cauſes apparently ſmall, we frequently tried to analyze the pleaſure he communicated to the audience, and found it chiefly aroſe from his artful manner of diminiſhing the tones of his voice, like the dying notes of the Æolian harp. Moſt other ſingers captivate by a ſwell, or *meſſa di voce*; but Guadagni, after beginning a note or paſſage with all the force he could ſafely exert, fined it off to a thread, and gave it all the effect of extreme diſtance. And though neither his voice nor execution contributed much to charm or excite admiration, he had a ſtrong party in England of enthuſiaſtic friends and adherents, of whom, by perſonal quarrels and native caprice, he contrived to diminiſh the number very conſiderably before his departure. He had ſtrong reſentments, and high notions of his own importance and profeſſion, which revolted many of his warmeſt friends, and augmented the malice of his enemies.

The ſerious operas in which he performed during the ſeaſon of 1769 and 1770, were Olimpiade, a paſticcio, but chiefly by Piccini, though the favourite ſong was "Quel labbro addorato," by Bach; Ezio by Guglielmi; and Orfeo, by Gluck. In this laſt drama his attitudes, action, and impaſſioned and exquiſite manner of ſinging the ſimple and ballad-like air, "Che farò," acquired him very great and juſt applauſe; but in the midſt of the utmoſt public favour, his private difference with the Hon. Mr. Hobart, the patentee at that time, concerning an imagined affront put upon his ſiſter in favour of Zamparini, together with his determined ſpirit of ſupporting the dignity and propriety of his dramatic character, by not bowing acknowledgment, when applauded, or deſtroying all theatrical illuſion, by returning to repeat an air, if encored at the termination of an intereſting ſcene, he ſo much offended individuals, and the opera audience in general, that, at length, he never appeared without being hiſſed. His enemies, knowing him to be *paſſion's ſlave*, frequently began an encore, with which they knew he would not comply, on purpoſe to enrage the audience. Guadagni was allowed to be the fineſt billiard player in Europe; but his antagoniſt, diſcovering his irritability, uſed, when he was playing for large ſums, to diſpute, as unfair, ſomething that was clearly otherwiſe, by which he was ſo agitated, as not to be a match for a child. He quitted England for the laſt time in the ſummer of 1771; in 1772 he performed at Verona, and afterwards accompanied the late electreſs dowager of Saxony, a dilettante of the firſt order in abilities as well as rank, to Munich, where he continued till 1776, when he appeared

appeared on the ſtage, for the laſt time, at Venice. After which he ſettled at Padua in the ſervice of Sant' Antonio, where he loſt his ſight in 1786, by a paralytic ſtroke, and ſoon after his life.

The declenſion of a great ſinger, who has not had prudence to realize an independence during proſperity, ſeems the moſt humiliating that a fallen favourite can feel. And the proud and lofty minded Guadagni, bereaved of his talents and public favour, by age, infirmities, and caprice, ſpent the laſt ten years of his life in indigence and mortification!

GUADAGNI, LA SIGNORA, ſiſter of Guadagni, a moſt pleaſing ſinger and elegant actreſs, was the original Cuchina in Italy, as well as England, in Piccini's celebrated "Buona Figliuola." She was married to Aleſſandri, a young Roman compoſer, who ſet two comic operas for our ſtage, "La Moglie Fidele," and "Il Re alla Caccia;" which are not devoid of merit; but there were ſo many maſters here at this time, whoſe fame was already eſtabliſhed, that a young compoſer, who had his reputation to make, had little chance of being much noticed. He has, however, diſtinguiſhed himſelf, ſince he left England, by writing for ſome of the firſt ſingers in the principal theatres of Italy. He ſtaid here but one ſeaſon, his wife, Signora Guadagni, having been ſuperſeded by Zamparini, a pretty woman, but an affected ſinger, which pleaſed the votaries of beauty, more than the *conoſcenti* in good ſinging.

GUADAGNOLI, PHILIP, a learned Orientaliſt, who flouriſhed in the 17th century, was born at Magliano about the year 1596. At the age of ſixteen he entered among the regular clerks minors; and made his profeſſion at Rome in 1612. He devoted himſelf moſt aſſiduouſly to the ſtudy of the Oriental languages, and he ſpent a great part of his life in tranſlating works from the Arabic. He was choſen profeſſor of the Arabic and Chaldee in the College of Wiſdom; and in 1656 he pronounced an oration in the former language before queen Chriſtina of Sweden. He afterwards was employed with others in furniſhing a correct Arabic verſion of the whole bible; this grand deſign almoſt wholly employed him twenty-ſeven years. It was completed in 1649, but was not publiſhed till ſome years after the author's death, *viz.* in 1671. In anſwer to ſome objections of a learned Perſian, to Chriſtianity, he publiſhed "Apologia pro Religione Chriſtiana." This work he undertook by the expreſs orders of pope Urban VIII., and he performed the taſk ſo much to the ſatisfaction of the Perſian, to whom it was ſent, that he immediately renounced the Mahometan faith, and became a zealous advocate for the Chriſtian religion, which he had formerly oppoſed. This work was publiſhed in Arabic in 1637, and the author next wrote a piece entitled "Conſiderations againſt the Mahometan Religion," which was printed at Rome in 1649, and which is intended to ſhew that the Koran is a mere rhapſody of impoſtures and falſehoods. He was author likewiſe of an Arabic grammar, entitled "Breves Inſtitutiones Linguæ Arabicæ," folio; and of a dictionary of the ſame language. He died at Rome in the year 1656.

GUADALAJARA, or GUADALAXARA, in *Geography*, an ancient town of Spain, ſituated on a plain near the eaſtern bank of the Henarez, and the chief town of the beautiful canton of Alcarria in New Caſtile. It was formerly inhabited by the Romans, who named it, according to ſome, Arriaca and Carraca, and, according to others, Turria. From the Romans it paſſed under the dominion of the Goths, and was conquered by the Moors in 714, who called it Guidalhichara or Guidalarrica, whence it derived its preſent name. It was retaken by Alvar Fanez, couſin of the Cid, for king Alphonſo the Firſt of Caſtile, and VIth of Leon. It is large, but ill-built; it was formerly ſurrounded by ſtrong walls, of which ſome ruins remain; and it received, in 1464, from Henry IV. of Caſtile, the title of city, and the right of ſending deputies to the ſtates-general of the kingdom. Its population, according to Mr. Townſend, conſiſts of 16,000 perſons; it is divided into 10 pariſhes, and contains ſix monaſteries, ſeven convents, two hoſpitals, and eight hermitages, chapels or private oratories. The monaſtery of the order of St. Anthony was ſuppreſſed in 1791. It is the chief place under the controul of an intendant and corrigidor, and the place of reſidence of both, as well as of an alcade mayor. The palace of the family of Infantado is of conſiderable extent, conſtructed without much taſte, but within richly ornamented and furniſhed. It is rendered famous by the royal manufactory of broad cloth, which is of different qualities, and particularly of that ſpecies of cloth, which is made of Vigogna or Vigonia wool, obtained from Buenos-Ayres and Peru. In this manufactory the king has been accuſtomed to employ about 4000 people, to whom he pays every month 600,000 reals, or 6000*l*, beſides about 40,000 ſpinners ſcattered in the ſurrounding villages. This manufacture was firſt projected by the baron de Riperda, A.D. 1720; but it was carried on for ſome years without much ſucceſs. Another ſimilar manufacture at St. Fernando was united to this, A.D. 1755, and transferred by government to the Gremias; but after a few years, A.D. 1768, the king once more undertook to manage both on his own account; but they have not proſpered; 22 miles N.E. of Madrid. N. lat. 40° 35′. W. long 3° 32′.—Alſo, a river of Spain, which runs into the ſea, between Gibraltar and Marbella.

GUADALAJARA, or *Guadalaxara*, an audience of Mexico or New Spain, which extends over all the northern provinces, and comprehends Guadalaxara proper, Xaliſco or New Gallicia, Zacatecas, New Biſcay, Cinaloa, and Culiacan.

GUADALAJARA, or *Guadalaxara*, a city of Mexico, the capital of Guadalaxara proper, the ſee of a biſhop, and the ſeat of the royal audience, eſtabliſhed in 1548. This city is more extenſive than populous, containing from eight to nine thouſand families of Spaniards, Meſtizos, and Mulattoes; for the Indians, who live in farms and villages, cannot be included. It has eight ſquares, many convents, and two colleges for education. It is ſituated on the river Barnaja, or Eſquitlan, which flows from the lake of Mechoacan, and runs rapidly to the N.W., there being a cataract at the diſtance of four leagues. The plain on which it ſtands is watered by many rivulets, and ſurrounded with hills, overſhadowed by pines and oaks. This city boaſts of ſkilful artiſans, and the people are generally fair and well-formed, and celebrated for induſtry and honeſty. Here is a handſome aqueduct, and to the city belong numerous gardens, abounding with excellent fruits. The ſtreets are unpaved, and the carriages are drawn by unſhod mules, which are fed with maize at the price of four reals per buſhel. It is ſubject to frequent tempeſts, but it has never any ſnow. In this town there is eſtabliſhed a manufacture of cigars, the ſale of which contributes to the revenue. It is alſo famous for its earthen jars, which are of a ſweet ſcent, and are conveyed as far as Spain, where, it is ſaid, they are eaten by ſome capricious females. Near Guadalaxara is the celebrated eſtate of the marquis of Altamira, about 40 leagues in extent, which ſends annually to Mexico between three and four thouſand beeves. It is alſo very productive of wheat, pimento, &c. with numerous flocks of ſheep and ſwine; but markets are wanting. According to Eſtalla, cited by Pinkerton,

kerton, the eſtate might yield 40,000 peſos a year. The biſhopric of Guadalaxara yields, in tithes, 2,579,108 peſos annually. N. lat 1° 20′. W. long. 104° 16′.

GUADALAJARA *de Buga*, a town of South America, in the province of Popayan; 36 miles N.W. of Popayan.

GUADALAVIAS, a river of Spain, which runs into the ſea near Valentia. N. lat. 39° 25′.

GUADAL-CANAL, one of the iſlands of Solomon, in the ſouthern Pacific ocean.—Alſo, a little walled town of Spain, in the province of Andaluſia, environed by a branch of the Sierra Morena, formerly noted for mines of quickſilver, which have been long neglected, and lately in vain explored: about a mile to the N.E. of it are ſilver mines, which are ſaid by De Laborde to yield a conſiderable revenue. This ſmall town contains about 1000 inhabitants, two pariſhes, and four convents; 19 leagues N. of Seville.

GUADALCAZAR, a town of Spain, in the province of Cordova; 12 miles S.W. of Cordova.—Alſo, a town of Mexico; 50 miles N.E. of St. Luis de Potoſi.

GUADAL-MEDINA, a river of Spain, which runs into the ſea near Malaga, and which is ſubject to inundations that incommode and injure thoſe parts of the town that are neareſt to it.

GUADALOUPE, one of the largeſt of the Caribbee or Leeward iſlands in the Weſt Indies, which, including "Grand Terre" and "Baſſe-Terre," is about 60 Britiſh miles in length, and 25 in breadth. Its form is ſomewhat ſingular, as it is divided into the two parts above-named by a narrow channel, which is navigable only by boats. This channel, which is an arm of the ſea, runs N. and S.; the portion on the N.E. of it is called "La Grande Terre," and the other on the S.W. the "Baſſe-Terre," but more generally Guadaloupe. This channel communicates with the ſea at both extremities, that on the N. being denominated "Grand Cul-de-Sac;" and that on the S. "Petit Cul-de-Sac." The part called "Grande-Terre" is about 57 miles from Antigua point on the N.W. to the point of Guadaloupe on the S.E., and 29 miles in the middle, where it is broadeſt, about 120 miles in circumference; and the other part is ſubdivided by a ridge of mountains into "Capes-Terre" on the W., and "Baſſe-Terre" on the E. This part is 36 miles from N. to S., and 23 in its greateſt breadth; and about 120 in circuit. The limb of the ſea, which ſeparates the portion called "Grande-Terre" from Guadaloupe proper is, according to Labat, about 50 fathoms wide at its northern mouth, but in ſome parts it is not above 15 fathoms. The depth is ſuch in ſome parts as to admit a ſhip of 500 tons, while in others a bark of 50 tons could not paſs at low water. The breadth is often confined by mangrove trees; but the navigation is pleaſant, the water being generally calm and clear like a mirror; and the length is about two leagues. The French were, in 1696, obliged to abandon Grande-Terre on account of the frequent incurſions and depredations committed there by the Engliſh from Antigua and Montſerrat; and, beſides, this part is deſtitute of freſh water. The air in the part of the iſland called Guadaloupe is clear and ſalubrious, and leſs incommoded with heat than that of Martinico. It alſo abounds with good water; the ſoil is rich, and well cultivated, and produces, like that of Martinico, ſugar, cotton, indigo, coffee, ginger, and various fruits. Among the vegetable productions are the tree, which yields the copaiba-balſam; the milk ſhrub yielding a liquor like milk; the moubane-tree, furniſhing a kind of plum, which is uſed for fattening hogs; the corbary tree, which yields a gum ſimilar to amber; a kind of cinnamon-tree, aloes, and ſandal-wood. The birds are parrots, partridges, turtle-doves, herons, and falcons, and an extraordinary bird, called "devil-bird," which is a fiſhing bird of paſſage, about the ſize of a young pullet, with jet-black plumage. The bees are black, ſmall, and without ſting; and the honey produced by them retains the conſiſtence of oil. A ſtinking inſect, called ravet, is ſaid to be very troubleſome in this iſland, gnawing paper, books, and furniture, but it is deſtroyed by a large ſpider. On the weſtern ſhore Labat deſcribes a ſingular phenomenon; the ſea being ſo hot, at a ſmall diſtance from the ſhore, as to boil eggs; and on moving the ſand a ſtrong ſmell of ſulphur is perceived. There are alſo a boiling fountain, and a hot marſh, the latter of which is very deceitful and dangerous to ſtrangers. Labat alſo viſited and has deſcribed the "Soufriere" or Solfaterra of Guadaloupe. This eminence commands an extenſive view, but in aſcending it, burnt ſtones occur, and places covered with white aſhes, ſmelling ſtrongly of ſulphur. The ſummit is a large platform, ſurrounded with burnt ſtones, and ſmoke iſſuing from holes and crevices. The mouth of the volcano is perceived on the E.; and Labat obſerved other apertures in this volcanic mountain. The air on the ſummit is very cold; but the negroes frequently aſcend it to gather ſulphur, which they purify and ſell. There are ſeveral pools in this mountain, and ſprings which unite and form torrents.

Guadaloupe was firſt diſcovered by Columbus, who gave it this name from a fancied reſemblance to the mountain ſo called in Old Spain. His landing was oppoſed by the women of the iſland, who attacked the ſtrange viſitors with bows and arrows; but the fire-arms of the Spaniards ſoon diſperſed them, and they obtained a very eaſy poſſeſſion of the iſland. Few of the original inhabitants, or Charaibes, now remain. This iſland was firſt ſettled by 550 French, under the conduct of Loline and Dupleſſis in 1635; but ſo ſlow was their progreſs, that, in 1700, there were only 3825 white inhabitants, 325 free people of colour, and 6725 ſlaves, of whom a conſiderable portion conſiſted of Charaibes. There were only 60 ſmall manufactories of ſugar, and 66 of indigo, with ſome cotton, and a little cacao. The horſes, mules, and aſſes were 1620; and the beeves 3699. In 1755, the colony was peopled by 9643 whites, and 41,140 ſlaves. There were 334 ſugar houſes; and the cotton, coffee, cacao had increaſed in a like proportion, while tobacco and indigo were added to the produce. The banana trees, for the food of the ſlaves, were computed at 2,028,520; with 32,577,950 ditches of manioc. The horſes amounted to 4946, mules 2924, aſſes 125; with 13,916 beeves, 11,162 ſheep and goats, and 2444 ſwine. In the month of April 1759 it was conquered by the Engliſh, who farther contributed to its proſperity. In 1763 it was reſtored to France. In 1767 the valuation exceeded that of 1755. France at that time received from Guadaloupe 140,418 quintals of fine ſugar; 23,603 of raw ſugar; 34,205 of coffee; 11,955 of cotton; 456 quintals of cacao; 1884 of ginger; 2529 of campeachy-wood; with 24 boxes of confections, 165 boxes of liqueurs, 34 caſks of ratafia, and 1202 ſkins. Theſe articles were ſold in the colony for 7,103,838 livres; while the merchandiſe received from France only coſt 4,523,884 livres. It was ſuſpected that much of the produce was ſmuggled, as it was well known to exceed that of Martinico. Pinkerton's Geography, vol. iii. In April 1794 Guadaloupe was taken by the Britiſh troops, but evacuated in February 1795. It was taken again in February, 1810. N. lat. 15° 5′ to 16° 37′. W. long. 61° to 72° 15′.

GUADALOUPE, an iſland in the N. Pacific ocean, compoſed of high, naked, rocky mountains; about 13 miles long, nearly in a north and ſouth direction, with two rocky iſlets, one lying W.S.W. half a league, the other two miles

S. from

S. from its S. point. N. lat. 29°. E. long. 241° 38'.—Alſo, one of the Solomon iſlands in the Pacific ocean. S. lat. 9° 30'.

GUADALQUIVIR, the ancient *Bætis* or *Tarteſſus*, a river of Spain, which originates at the foot of mount Segura, and after purſuing a ſluggiſh courſe of about 340 miles through New Caſtile, diſcharges itſelf into the ſea, about 18 miles N.W. of Cadiz; N. lat. 36° 46'. W. long. 6° 26'.

GUADALQUIVIREJO, a river of Spain, which runs into the ſea, about five miles S.S.W. of Malaga; N. lat. 36° 40'. W. long. 4° 35'.

GUADALUPA, a ſmall tolerably built town, in a valley watered by a ſtream of the ſame name, and abounding with vines, orange-trees, fig-trees, and other fruits; 25 leagues W.S.W. of Toledo.

GUADALUPE, a town of Mexico, in New Biſcay; 70 miles N. of Parral.—Alſo, a town of New Mexico, in the province of Mayo; 100 miles E. of Santa Cruz.—Alſo, a town of New Mexico; 15 miles W. of Sumas.—Alſo, a river called alſo *Magdalena*, ſituated between the Rio Bravo and the Miſſiſippi, that runs into a bay of the gulf of Mexico.

GUADARRAMA, a mountain of Spain, which ſeparates the two Caſtiles, over which is formed a road by order of Ferdinand VI. commencing at the village of Eſpinar, which renders the aſcent eaſy and pleaſant. The ſummit, on which is a marble monument to the memory of this prince, commands an extenſive view of the whole range of country included in the two provinces of Old and New Caſtile.—Alſo, a river of New Caſtile, which riſes near a village of the ſame name, famous for its cheeſe, and runs into the Tagus, about nine miles below Toledo.

GUADEL, a ſea-port town of Perſia, in the province of Mecran, on the coaſt of the Arabian ſea, ſituated in a bay, and near a cape, to both of which it gives name. The inhabitants are chiefly weavers; but the trade has declined. N. lat. 25° 16'. E. long. 62°.

GUADEN, or HADEN, a town of Africa, in the deſert of Zanhaga. N. lat. 21° 40'. W. long. 13°.

GUADIANA, a town of Mexico, in the province of Biſcay, ſituated on a river of the ſame name; 40 miles N. of Durango. N. lat. 24° 50'. W. long. 104° 56'.—Alſo, a navigable river of Spain, anciently called *Anas*, which takes its riſe in ſome lakes or marſhes N.W. of Alcaraz in New Caſtile; it ſoon afterwards loſes itſelf in the earth, and ſprings up again through various apertures called the "eyes of the Guadiana;" then flowing weſterly, it enters the confines of Portugal, near Badajoz, and ſuddenly again changing its direction, it purſues a ſoutherly courſe to the ocean, between Ayamonte and Caſtel Marin; N. lat. 37° 10'. W. long. 7° 26.

GUADIX, a town of Spain, in the province of Granada, which is the ſee of a biſhop, ſuffragan of Seville. This town was taken from the Moors by Alphonſo in 1252, and again loſt to them; from whom it was taken by Ferdinand the Catholic. It contains five pariſhes, ſeven convents, and 8000 inhabitants, and is ſituated on a declivity eight leagues E. of Granada, in a valley encompaſſed on all ſides by high, bleak, and irregular clay hills, waſhed into broken maſſes reſembling ſpires, towers, and miſ-ſhapen rocks. Whole villages are dug in theſe hills: but the adjacent diſtrict is little cultivated; however, it produces grain, wine, and good paſtures, but no oranges nor olives. Guadix is noted for the manufacture of pocket knives. N. lat. 37° 24'. W. long. 3 9'.

GUADUM, in *Natural Hiſtory*, an herb by the ancient Romans called *glaſtum* and *vitrum*; by the Greeks *iſatis*; by the Britons *gundum*; and by us *woad*. See GLASS.

GUAFFO, in *Geography*. See COMMENDO.

GUAGAMOW, a town of Hindooſtan, in Oude; 37 miles N.N.W. of Manichpour.

GUAGE-PADDLES, or *Guage-weirs*, are contrivances for letting off a certain limited quantity of water per day or hour, from a canal or reſervoir, &c. See GAUGE.

GUAGING-MASTER, the officer appointed to guage or aſcertain the tonnage or lading which boats carry at different depths of lading.

GUAGIROS, in *Geography*. See GOAHIROS.

GUAGNINI, ALEXANDER, in *Biography*, born at Verona in 1538, was author of "Sarmatiæ Europæ Deſcriptio," a rare and highly eſteemed work. He publiſhed "Rerum Polonicarum Scriptores," in three volumes, of which the firſt volume is a compendium of the chronicles of Poland. He died at Cracow in 1614.

GUAGUAS, a tribe of ſavage Indians, in S. America, in the lately explored territory of the PAMPAS *del Sacramento*, who inhabit the banks of the Yupura, which joins the Maranon from the north. Theſe ſavages are Anthropophagi; and return from war with the hearts of their enemies faſtened round their necks. They even ſalt human fleſh, and regard it as a moſt ſavoury regale. They run like hares; and by compreſſure from their infancy, reduce their bellies to an inconceivably ſmall ſize.

GUAIACANA, in *Botany*. See DIOSPYROS.

GUAIACANÆ, the 49th natural order of plants in Juſſieu's ſyſtem, and the firſt of his 9th claſs, ſo named from the firſt genus in it, *Guaïacana* of Tournefort, *Dioſpyros* of Linnæus, Juſſieu, and others. The character of the claſs is to have two cotyledons, a monopetalous corolla, inſerted into the calyx, and ſtamens inſerted either into the one or the other. The order of *Guaïacanæ* is thus defined. *Calyx* of one leaf, divided at the ſummit. *Corolla* inſerted either into the bottom or top of the calyx, lobed more or leſs deeply. *Stamens* inſerted into the corolla, either definite in number, when they are equal to, or double, the number of its ſegments; or numerous and indefinite, in which caſe their filaments are often united at the baſe into one or ſeveral ſets. *Germen* in moſt caſes ſuperior, in a few inferior, or half-inferior; ſtyle one; ſtigma either ſimple or divided. *Fruit* ſuperior, or ſometimes inferior, either capſular, or more frequently pulpy, of many cells, with one ſeed in each. *Corculum* of the ſeed flat, in a fleſhy *albumen*. *Stem* ſhrubby or arboreſcent. *Leaves* alternate. *Flowers* axillary.

The firſt ſection, with a definite number of ſtamens, contains *Dioſpyros*, (ſee that article, and EMBRYOPTERIS,) *Röyena*, *Labatia* of Schreber, which is *Pouteria* of Aublet, *Styrax* and *Haleſia*. The ſecond ſection, with indefinite ſtamens, contains *Alſtonia*, *Symplocos*, *Ciponima* of Aublet, *Paralea* of the ſame, and *Hopea* of Garden and Linnæus. All theſe ſuppoſed genera were conſidered as one by L'Heritier, and called *Symplocos*, that being the oldeſt name among the whole.

GUAIACUM, a barbarous name, derived from the Spaniſh one *Guaiac* or *Guayacan*, which itſelf originated from *Hoaxacan*, the Mexican appellation of the ſame plant. Plum. Nov. Gen. 39. t. 17. Linn. Gen. 208. Schreb. 287. Willd. Sp. Pl. v. 2. 538. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 56. Juſſ. 296. Lamarck. Illuſtr. t. 342. Gærtn. t. 113.—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Gruinales*, Linn. *Rutaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five ovate-oblong, obtuſe, concave, ſpreading, deciduous leaves; the two outer ones rather the ſmalleſt. *Cor.* Petals five, roundiſh-obovate, obtuſe,

obtuſe, concave, ſpreading, longer than the calyx, with ſhort linear claws, inſerted into the receptacle. *Stam.* Filaments, ten, awl-ſhaped, erect, ſmooth, ſhorter than the corolla, inſerted into the receptacle; anthers incumbent, oblong, cloven at each end, at length recurved. *Piſt.* Germen on a ſhort ſtalk, turbinate, lobed, angular; ſtyle ſhort, awl-ſhaped; ſtigma ſimple, acute. *Peric.* Capſule ſomewhat turbinate, ſtalked, with from two to five rounded, ſlightly bordered, angles, and as many cells, burſting at the angles, the partitions from the centre of each valve, the other coat rather pulpy. *Seeds* ſolitary, pendulous, ovate, convex on one ſide, angular at the other.

Eſſ. Ch. Calyx of five unequal leaves. Petals five. Stamens ſimple. Stigma acute. Capſule ſtalked, of five cells and five valves, with contrary partitions. Seeds ſolitary, pendulous.

Obſ. The natural number of cells and valves of the fruit is five, but there are moſtly but two or three, not perhaps from abortion, except in the very earlieſt ſtate of the germen long before fecundation can take place, becauſe that part is, even at that early age, frequently found to conſiſt of only two lobes, reſembling the pouch of cruciform ſiliculoſe plants.

1. G. *officinale*. Linn. Sp. Pl. 546. Woodv. Med. Bot. t. 16. (G. jamaicenſe; Pluk. Phyt. t. 35. f. 3, 4. Lignum vitæ; Sloane Jam. v. 2. 134. t. 222. f. 3—6)—Leaves of two pair of elliptical obtuſe leaflets.—Native of Jamaica, Hiſpaniola, &c. A *tree* 30 feet high, and near a foot in the diameter of its trunk, the branches numerous, divaricated, knotty, leafy at the ends; the bark very ſmooth, variegated with green and white; the wood hard and ponderous, dark olive-brown within, whitiſh towards the bark, having a peculiar acid aromatic ſcent, and well known in England by the name of Braſil wood, or *Lignum vitæ*. The *leaves* are oppoſite, abruptly pinnate, conſiſting of only two pair of obovate or roundiſh, obtuſe, entire, ſmooth, pale, rigid, leaflets, various in ſize, with ſeveral radiating veins. *Flowers* pale blue, on ſimple, axillary, cluſtered ſtalks, ſhorter than the leaves. The wood and bark were celebrated remedies for venereal complaints, before mercury came into uſe, as the gum or reſin ſtill is for rheumatic diſorders.

2. G. *ſanctum*. Linn. Sp. Pl. 547. (G. americanum, lentiſci folio; Comm. Hort. Amſt. v. 1. 171. t. 88. Hoaxacan, ſive Lignum ſanctum; Hernand. Mex. 63. Jaſminum vulgo Americanum; Pluk. Phyt. t. 94. f. 4.)—Leaves of many pair of ſpreading oblique leaflets.—Native of various hot parts of South America. A middle-ſized knotty *tree*, whoſe wood, according to Hernandez, is internally blue. The *leaflets* are about ſeven or eight pair, ſmaller than in the former, and oblique or unequal-ſided, obtuſe, veiny, ſometimes ſpeckled with black. *Flowers* rather corymboſe, pale yellow. The wood of this ſpecies was firſt introduced as a cure for the venereal diſeaſe by the Spaniards, and being carried to the Eaſt Indies, fetched there an extravagant price, till it became more plentiful.

3. G. *dulcum*. Forſt. Prod. 32.—Leaves conjugate, oblong, lanceolate, obtuſe.—Gathered by Forſter in the iſland of Tongatabu.—Of this we know nothing more.

4. G. *officinale*. Linn. Sp. Pl. 547. is the beautiful *Sebotia ſpecioſa* of Jacquin, Ic. Rar. t. 75. See SEBOTIA.

The common *lignum vitæ*, or *guaiacum*, which is uſed in medicine, grows naturally in moſt of the iſlands of the Weſt Indies, and the warm parts of America, where it becomes a very large tree, having a brownish, hard, brittle bark, not very thick; the wood is ſolid and ponderous, very reſinous, of a blackiſh yellow in the middle, and of a hot aromatic taſte; the ſmaller branches have an aſh-coloured bark, and are garniſhed with leaves divided by pairs; each pair having two pair of ſmall oval blunt pinnæ, of a ſtiff conſiſtence, and a lucid green; the flowers are produced in cluſters at the ends of the branches, compoſed of five oval concave petals, of a fine blue colour; in the centre of theſe is fixed a ſtyle with an oval germen, crowned by a ſlender ſtigma; and round this is ſituated a great number of ſtamina, which are as long as the ſtyle, is terminated by ſickle-ſhaped ſummits. The wood of this tree is ſo hard as to break the tools in felling them, ſo that it is ſeldom cut down for firewood, being difficult to burn; but is of great uſe to the ſugar-planters for making wheels and cogs for ſugar mills. It is alſo frequently brought to Europe, and wrought into bows and other utenſils. Miller.

GUAIACUM, in the *Materia Medica*, is a ſpecies of the tree above-deſcribed. The wood, gum, bark, fruit, and even the flowers of this tree, poſſeſs medicinal qualities. The *wood* is brought here principally from Jamaica, in large pieces of four or five cwt. each, and, on account of its hardneſs and beauty, is much valued for various articles of turnery ware, &c. It is very compact, and ſpecifically heavier than water; the colour of the outer part is a pale yelloviſh, that of the heart a dark blackiſh brown, with a mixture of green. Without heating or raſping it has little perceptible ſmell, but during theſe operations its odour is ſlightly aromatic; when chewed it is ſlightly acrimonious. Its pungency reſides in a reſinous matter, which is totally extracted by digeſtion in rectified ſpirit, and partially by boiling water. The ſolid extract, obtained by rectified ſpirit, amounts to about one-fourth of the weight of the wood; with water, ſcarcely one-ſixth is obtained. (Lewis's Mat. Med.) The *gum*, or rather gummy reſin, is obtained by wounding the bark in different parts of the body of the tree, or by an operation called "jagging." It exudes copiouſly, though gradually, from the wounds; and when a ſufficient quantity has been diſcharged and hardened by expoſure to the ſun, it is gathered and packed in ſmall kegs for exportation. This reſin is of a friable texture, of a deep greeniſh colour, and ſometimes of a reddiſh hue; its taſte is pungent and acrid, but unleſs heated, it has little or no ſmell. It contains more reſin than the watery extract obtained from the wood, and more gummy matter than the ſpirituous extract. The bark of the guaiacum trees yields a ſpontaneous exudation, called the native gum, which is brought to us in ſmall irregular pieces of a bright ſemi-pellucid appearance, differing from the former in its much greater purity. This is ſometimes ſophiſticated by the negroes with the gum of the manchineal tree; but the ſophiſtication may be eaſily detected by diſſolving a ſmall quantity in ſpirit of wine or rum; the true gum imparts a whitiſh or milky tinge; but the manchineal gives a greeniſh caſt. Or, a few drops of ſpirit. nitri dulc. may be added to the ſpirituous ſolution, and then diluted with water, by which the gum is precipitated in a blue powder, whereas the adulteration will appear floating in white ſtriæ, &c. The *bark* contains leſs reſinous matter than the wood, and of courſe is leſs powerful, though in a recent ſtate it is ſtrongly cathartic. The *fruit* is ſaid to be purgative, and, for medicinal uſe, to excel the bark. A decoction of it has been known to cure the venereal diſeaſe, and even the yaws in its advanced ſtage, without the uſe of mercury. The *flowers*, or bloſſoms, are laxative, and are given in Jamaica to children in the form of ſyrup. However, the wood and reſin of guaiacum are the only parts now generally uſed medicinally in Europe. Guaiacum was introduced in the Materia Medica ſoon after the diſcovery of America, and, previouſly to the uſe of mercury, it was conſidered as an antidote to the lues venerea, and ſold for ſeven

gold crowns a pound; but it often failed in curing the patient, and was, therefore, ſuperſeded by mercury; though it is ſtill occaſionally uſed for correcting a vitiated habit, rather than for its effects as an anti-venereal. Nevertheleſs, ſome opinions and facts adduced by Boerhaave, Aſtruc, Plenk, De Haen, Hutten, and lately by Mr. Hunter, may be conſidered in ſome meaſure as exceptions. The general virtues of guaiacum are ſtated by Bergius to be "mundificans, ſudorifera, diuretica, ſubcalefaciens, ſtomachica," and its uſe to be in "ſyphilis, arthritis, morbi cutis, odontalgia," to which may be added chronic rheumatiſms, ſcrophula, and ſome ſchirrous diſeaſes. Dr. Cullen, conceiving guaiacum as analogous to the nature of the balſams and turpentines, ſuppoſes that, like theſe, it is very diffuſible in the ſyſtem, and has conſiderable efficacy in ſtimulating the extreme veſſels every where; and thus he accounts for its power in chronic rheumatiſms; and from its paſſing off by the pores of the ſkin, he thinks that it is a probable remedy in ſome cutaneous diſorders. This opinion correſponds with Murray's. According to Lewis, where the excretory glands are obſtructed, the veſſels lax and flaccid, and the habit replete with ſerous humours, it has good effects; but in thin emaciated habits, and an acrimonious ſtate of the fluids, it often does harm. Dr. Woodville ſays, that he has frequently conjoined it with mercury and ſoap, and in ſome caſes with bark and ſteel, and found it eminently uſeful as an alterative. In the pharmacopœias it is directed in the form of tincture and elixir; the latter is ordered by the Edinburgh College to be prepared two ways, *viz.* with rectified ſpirit, and the vinous ſpirit of ſal ammoniac. Of theſe compounds the doſe may be from two ſcruples to two drams: the powder is generally given from ſix grains to twenty, or even more, for a doſe, either by itſelf, or in a fluid form, by means of mucilage or the yolk of egg. The "decoctum lignorum," (Pharm. Ed.) of which guaiacum is the chief ingredient, is commonly taken in the quantity of a pint a day. The "mixture of guaiacum" of the London pharmacopœia, or "lac guiaci" of P. L. 1787, is prepared of guaiacum gum-reſin, 1½ dram; refined ſugar, two drams; mucilage of acacia gum, two fluidrams; and cinnamon-water, eight fluid-ounces. The guaiacum is rubbed with the ſugar, then with the mucilage, and when they are mixed the cinnamon-water is poured on gradually. The doſe for adults from ℥ss to ℥ii. The "tincture" is formed by macerating for 14 days half a pound of the gum-reſin powdered in two pints of rectified ſpirit, and then ſtraining. The doſe is ℥i to ℥ii. The "ammoniated tincture" is made by macerating for 14 days four ounces of the gum-reſin powdered in a pint and a half of compound ſpirit of ammonia, and then ſtraining. The doſe as before. Dr. Cullen, in imitation of Berger of Copenhagen, avoids the ſpirituous tincture of guaiacum, which has been ſometimes injurious, and employs the following preparation. Having firſt with an equal part of hard ſugar reduced the guaiacum to a fine powder, he applies ſome portion of the yolk of an egg, or of a mucilage of gum-arabic, and rubbing theſe together very carefully, he forms an emulſion with water or watery liquors. This preparation he gives over night in ſuch a quantity as may open the body once next day, which, he ſays, will happen to different perſons from doſes containing 15 to 20 grains of the guaiacum. Berger's formula is the following: R Gummi ℥ſs G. arabici ʒii: bene trita ſolv. in aquæ hyſſopi vel alius ſtillic. ʒix. Add ſacchar. ʒſs. m. d. s. ſolutio, [illegible] cochlearia majora mane et veſperi capiantur, ſuperbibendo libra una decocti hordei vel avenæ. Theden recommends the guaiacum made into pills with ſoap of almonds. Woodville Mat. Med.

The guaiac wood is diſtilled by putting thin ſhavings of it into a ſtone-ware retort, to which is to be fitted a large glaſs receiver, with a ſmall hole pierced in its ſide: and the diſtillation is to be promoted by a gradual fire. A liquor, like water, is obtained firſt, and then an acid, reddiſh, empyreumatic liquor, with a little reddiſh oil. In this proceſs a conſiderable quantity of air is diſcharged; which proves that this element is combined in certain bodies, and particularly in this.

GUAIAVA, in *Botany*, Tourn. t. 443. Gærtn. t. 38. See PSIDIUM.

GUAIBI COARA, in *Ichthyology*, the name of an American fiſh, called by the Portugueſe *barace de velha*. It is flat bodied, with a riſing back, and is uſually caught between five and eight inches long, and of about a third part of its length in breadth. It is caught among the rocks and about the ſhores, and it is eaten in conſiderable plenty in the Braſils, both by the natives and Portugueſe. Marcgrave's Hiſt. Braſil.

GUAINUMBI, in *Ornithology*. See TROCHILUS.

GUAIUCACHI, in *Geography*, a town of Peru, in the dioceſe of Guamanca; 45 miles N. of Guanca-Velica.

GUAKI, a town of Peru, in the audience of La Paz; 5 miles N.W. of La Paz.

GUALACLING, in *Ornithology*, the name given by the people of the Philippine iſlands to a ſpecies of bird of the ſtarling kind. It is of the bigneſs of the turtle; it feeds on fruits, and is a very briſk and lively bird. It appears to be of a plain black colour, except when viewed in the ſun, and then is ſeen to be of a vaſt variety of bright colours.

GUALAGA, in *Geography*, a river of South America, which riſes in S. lat. 10° 57', under the name of the Guanuco, from the lake Chiquiacoba, in the plains of Bombon, whence it paſſes to the N. receiving ſeveral rivers, and reaches the vicinity of the town of Leon de Guanuco, 10° 3'. After a precipitous courſe it receives the river Monzon, from the W. at N. lat. 9° 22', when, becoming more tranquil, it forms ſeveral iſlets, and in the province of Lamas acquires the name of the Gualaga. At 7° 10' it receives from the W. the river Moyobamba. After this, there are four dangerous rapids, before it reaches Ponguillo, at the extremity of the mountains. The breadth of the Gualaga is now 1200 feet; and paſſing through the province of Maynas, at 5° 4' S. lat it joins the falſe Maranon, being 450 yards wide and 34 deep, according to Sobreviela (cited by Pinkerton). At the confluence the Gualaga is divided into two branches, and a lake is formed about half a league in breadth, and 70 fathoms deep. During the courſe of a league, the force of each river ſeems equal; but at length the Tunguragua or Jeſuitic Maraion overcomes the Gualaga. The banks of the Gualaga are cloathed with beautiful trees, enlivened with a great variety of birds, and one ſhrub produces a kind of native wax or tallow.

GUALATA, a country of Africa, about 350 miles from the Atlantic. N lat. 23° 30', to 25° 30'. W. long. 5 to 8°.

GUALCAS, a town of Peru, in the dioceſe of Truxillo; 80 miles E. of Piura.

GUALDO-PRIORATO, GALEAZZO, in *Biography*, was born of a noble family at Vicenza, in 1606. Little is known of him in early life, but he became hiſtoriographer to the emperor, and was author of the "Hiſtory of the Wars of Ferdinand II. and III." "The Troubles of France from 1648 to 1654, with the continuation of the War between the two Crowns;" that "Of the Miniſtry of cardinal Mazarin," three volumes. "The Hiſtory of the emperor

Leopold," and other works. He died in 1678. His works, which are in the Italian language, are all written in an agreeable ſtyle.

GUALIBI, in *Geography*, a town of Africa; 30 miles W. of Fez.

GUALIOR. See GWALIOR.

GUALLARIPA, a town of Peru, in the dioceſe of Guamanga; 120 miles S. of Guamanga.

GUALRAICO, a town of the iſland of Cuba; 55 miles W.N.W. of Villa-del-Principe.

GUALTEIRI, or GUALTERO, a town of Italy, in the department of the Croſtolo; 13 miles N. of Reggio.

GUALTERUS, RODOLPHUS, in *Biography*, was born at Zurich in the year 1519, and became, at an early age, eminent for his acquaintance with the learned languages, the belles-lettres, and theology; to the illuſtration of the latter, his other acquirements were made ſubſervient. He officiated as paſtor at Zurich from the year 1542 to 1575, and then, on the death of Bullinger, he was choſen principal miniſter of the Proteſtant church in that city and diſtrict. He died in 1586, leaving behind him many theological works, which were highly eſteemed at that time. He was author likewiſe of different treatiſes in grammar, the belles-lettres, and hiſtory, and the tranſlator of ſome ſermons, homilies, &c.

GUAM, in *Geography*, one of the Marian, or Ladrone, iſlands, in the Eaſt Indian ſea, about nine miles in circumference. This is the only one of the Marian iſlands in which the Spaniards have a ſettlement. The principal town, which is the reſidence of the governor, and of the greateſt number of the inhabitants, is at the diſtance of four leagues in the country, ſituated on the N.W. of the iſland, on the border of a conſiderable river, at the mouth of which ſhips may anchor, though the road is not one of the beſt; but it is ſafe during the ſummer months. There is a fort about three leagues from the town. The ſoil is extremely fertile, producing rice, Indian corn, and vegetables in abundance. There are ſome cows, plenty of poultry, and many different kinds of fruit. The bread-tree, the cocoa, and fig-banian, are common in the woods of Guam, and the face of the country preſents numberleſs beautifully diverſified landſcapes, conſiſting of lawns, high woody hills, and vallies in excellent cultivation. The natives are tall and well-made, and, judging from the expreſſion of the countenance, of an open and generous character. They are accuſtomed to chew the betel; and they have an excellent kind of brandy manufactured from the fermented juice of the cocoa-tree.

The natives of the Philippine iſles pretend, that the inhabitants of Guam, and the other Marian iſlands, are originally deſcended in colonies from them. The Indians on this iſland may be computed at about 10,000, and they are diſtributed into ſeven or eight villages. The natives, it is ſaid, go naked, and never bury their dead, but leave them expoſed to the air. N. lat. 13° 25'. E. long. 155° 10'. De Pages' Travels, vol. i.

GUAMA, a river of Brazil, which runs into the Para, at the town of Para.

GUAMAJACU APE, in *Ichthyology*, a name by which Marcgrave and ſome others have called the *piſcis triangularis*, a ſpecies of *oſtracion*; which ſee.

GUAMAJACU *Atinga*. See DIODON *Atinga*.

GUAMAJACU *Guara*. See DIODON *Hyſtrix*.

GUAMALIA, in *Geography*, a diſtrict of Peru, in the archbiſhopric of Lima, ſituated in the centre of the Cordilleras. This juriſdiction commences at the diſtance of 240 miles N.E. from Lima, and being rather cold, few parts of it are fertile through its whole extent, which is above 120 miles. The Indian inhabitants of the towns apply to weaving, and manufacture a great variety of baizes, ſerges, and other ſtuffs, with which they carry on a conſiderable trade with the other provinces.—Alſo, a town of Peru, and capital of the above diſtrict; 150 miles E. of Truxillo.

GUAMANGA, an intendancy or juriſdiction of Peru, in a biſhopric of the ſame name; the ſoil of which is fertile in grain and fruit. The chief articles of commerce are cattle, hides, and ſweet-meats, beſides the produce of ſeveral mines, &c. In this intendancy, with its dependency of Lucanos, 60 mines of gold, 102 of ſilver, and one of quick-ſilver, were wrought in 1791. Of the firſt of theſe metals, three mines have been abandoned, and of the ſecond 63.—Alſo, a town of Peru, the ſee of a biſhop, ſuffragan to the archbiſhop of Lima. It was founded by Pizarro in 1539, in a wide and beautiful plain, watered by a river, and crowned with perpetual ſprings. The buildings are of ſtone, and thought to be ſuperior to any in Peru; while the gardens, ſquares, and chearful entrances of the city, decorated with trees, recommend a reſidence at Guamanga. The chief articles of trade are leather, grain, and fruit. In the diſtrict there is a fountain, which quickly impregnates a mould with a white and tranſparent ſtone. The ſtate of the population is not preciſely aſcertained. Among the inhabitants are 20 noble families, who live in a quarter of the town ſeparated from the reſt. It has three parochial churches, one for Spaniards, and two for Indians, beſides the cathedral, and ſeveral other churches and convents. It has alſo an univerſity, with a large revenue, for the ſtudy of philoſophy, divinity, and law. S. lat. 12° 50'. W. long. 77° 56'.

GUAMANTAGUA, a town of Peru, in the audience of Lima, and juriſdiction of Canta, in which is a celebrated image of Chriſt, which the inhabitants of Lima viſit in pilgrimage at Whitſuntide; 50 miles N.E. of Lima.

GUAMANUA, a town of the iſland of Cuba; 8 miles W. of Havannah.

GUAMARA, a river of Brazil, diſcharging itſelf into the Atlantic; 42 miles N. of Fernambuco.

GUAMOCO, a town of South America, in the province of Carthagena; 35 miles N.E. of Santa Fé de Antioquia.

GUAMUBO, a town of the iſland of Cuba; 20 miles E. of Havannah.

GUAMULOS, a town of Cuba; 63 miles S.E. of Santa Clara.

GUAN, in *Ornithology*. See PENELOPE *criſtata*.

GUANA, in *Geography*, a ſmall iſland in the Weſt Indies, N.E. of Antigua. N. lat. 17° 16'. W. long. 62'.

GUANA *Point*, a cape on the W. coaſt of the iſland of St. Chriſtopher's. N. lat. 17° 21'. W. long. 62° 23'.

GUANABANUS, in *Botany*, Plum. Nov. Gen. 42. t. 10. See ANNONA.

GUANACACHA, in *Geography*, a lake of South America, in the province of Chiquitos; 50 miles in circuit.

GUANACAS, a town of South America, in the province of Popayan; 40 miles N.E. of Popayan.

GUANACO, in *Zoology*. See CAMELUS *Huanacus*.

GUANAJO, or BONACAO, in *Geography*, an iſland in the bay of Honduras, about 60 miles in circumference, diſcovered by Columbus. N. lat. 16° 30'. W. long. 86° 23'.

GUANAJUATO, a mining ſtation of New Spain, ſituated between the two towns of Guadalaxara and Quarataro. This celebrated mining ſtation is in the Sierra Madre, or chain of Topia; and the mines produce abundance of gold, ſilver, and copper, but being carried to great depth, the expence of diſcharging the waters is conſiderable. The "Real," (a general name for the royal mining ſtations) of

St. Nicholas, is three leagues to the N. while others extend four leagues to the W. Within the mountains there are alſo five mining ſtations, each having a church, and chaplain to adminiſter the ſacrament; there are alſo in the vales 43 ſmelting houſes, giving bread to a great number of workmen, who conſume annually 100,000 loads of maize, 18,000 ſheep, 5000 beeves, and 18,000 loads of meal; the villages being 16 in the townſhip of Irapuato. In the diſtrict of this ſtation, there is a great number of looms for woollens, the deareſt being nine reals a yard.

GUANAPU, a town of Peru, in the dioceſe of Truxillo, ſituated on the coaſt; 25 miles S.S.E. of Truxillo.

GUANAPU, a river of Brazil, which, uniting with the Tocantins, forms the Para.

GUANARA, a town of S. America, in the province of Venezuela, fonnded in 1593 on a river, whence it has its name, which furniſhes the inhabitants with excellent water, floods their lands, and waters their cattle. On the weſtern part it has very fertile lands, and on the ſouthern and eaſtern immenſe plains, the paſtures of which are admirably adapted for the multiplication of cattle. The chief wealth of the inhabitants conſiſts in cattle, of which they poſſeſs very numerous herds. They ſupply the province with vaſt numbers of oxen, and alſo of mules; and export the ſurplus by Coro, Porto-Cavello, or Guiana. The population of this town conſiſts of 12,300 perſons: the ſtreets are ſtraight and wide, and the houſes, though not ſumptuous, tolerably well built. Here is a hoſpital with moderate revenue; and the church is large, handſome, and much adorned. Depons aſcribes its ſplendour to its being in poſſeſſion of our lady of Camoroto, whoſe virtues and miracles attract a great concourſe of viſitors from all the neighbouring provinces; 93 leagues S.W. from Caraccas, and 24 leagues S.E. from Truxillo. N. lat. 8° 14′. W. long. from Paris 72° 15′. Dupons' Travels, vol. ii.

GUANATAN, a town of S. America, in the audience of Quito; 35 miles N. of Loxa.

GUANBACHO, a town of Peru, in the dioceſe of Truxillo, on the coaſt. S. lat. 9° 22′.

GUANCA-BAMBA, a town of Peru, in the dioceſe of Truxillo; 70 miles E. of Piura.

GUANCANA, a town of Peru, in the dioceſe of La Paz, on the lake Titicaca.

GUANCA-VELICA, a town of Peru, in the dioceſe of Guamanga, and capital of a juriſdiction of the ſame name; 30 miles N.W. of Guamanga. This town was founded in 1572, by the viceroy, Don Franciſco de Toledo; it ſtands in a break of the Andes, and is one of the largeſt and richeſt cities of the viceroyalty. The temperature is very cold, and the climate changeable, as it ſometimes rains and freezes on the ſame day with tempeſts of thunder, lightning, and hail. The buildings are moſtly conſtructed of a kind of tufa, found near a warm ſpring in the vicinity. There is a dangerous torrent, which is paſſed by ſeveral bridges. The grand mine of quickſilver, in the vicinity, was diſcovered in 1563; it was managed by a company of forty, who delivered the quickſilver to the king at a certain price; but a fire in 1760 deſtroyed many of the works, and the mine has been ſince in conſiderable decay. S. lat. 12° 45′. W. long. 74 46′.

GUANCA-VELICA, or *Huanca-Velica*, a juriſdiction of S. America, in the biſhopric of Guamanga, or one of the provinces of the viceroyalty of Peru. The town, whence it derives its name, was founded on account of the rich quickſilver mines, from the working of which the inhabitants derive their whole ſubſiſtence. The cold temperature checking the growth of grain and fruits, they are ſupplied by their neighbours.

In this intendancy, with its dependencies of Caſtrovireyna and Lircay, 1 mine of gold, 80 of ſilver, 2 of quickſilver, and 10 of lead, were wrought in 1791; two of gold and 215 of ſilver were in an abandoned ſtate. The quickſilver mine was formerly much celebrated; but it appears to be nearly exhauſted, after having, in the courſe of two centuries, produced mercury to the value of more than 67,000,000 dollars. We learn from Helms, that at Guancavelica, a vein of cinnabar, 80 yards thick, is accompanied with galena, manganeſe, and arſenic. Behind Guancavelica, the argillite graduates into calcareous ſand-ſtone, as this does into ſimple limeſtone; all equally rich in gold, ſilver, and mercury.

GUANCHACO, a ſea-port of Peru, near Truxillo, of which it is the harbour.

GUANCHES, a river of Cuba, which runs into the Spaniſh Main, N. lat. 20° 4′. W. long. 75 51′.

GUANDAGNANO, a town of Italy, in Friuli; 29 miles N.W. of Friuli.

GUANGON, a town on the N. coaſt of the iſland of Luçon. N. lat. 18 24′. E. long. 121 58′.

GUANJAYA, a town of Peru, in the dioceſe of Guamanga; 50 miles N. of Guancavelica.

GUANJOOK, a town of Abyſſinia; 20 miles S.W. of Tcherkin.

GUANO, a town of S. America, in the province of Quito; 10 miles N.E. of Riobamba.

GUANO *Key*, *Great* and *Little*, two ſmall iſlands belonging to the Bahamas; the former in N. lat. 26 30′. W. long. 77° 30′; and the latter in N. lat. 26 18′. W. long. 77° 5′.

GUANO, in *Geology*, a yellowiſh-brown earthy ſubſtance of a peculiar kind, without taſte and of a ſmell reſembling that of caſtoreum. This ſubſtance, which for centuries has been uſed by the Peruvians as a manure, is the production of ſome neighbouring rocky iſlands in the South ſea, from whence large quantities are annually brought to the continent of America. Indeed, Peru, without this ſubſtance, would be nothing but a barren deſart.

The guano has been mentioned by ſeveral early travellers in South America, and it has even been conjectured to be the dung of birds; but ever ſince the time of Ulloa it has fallen into oblivion, from which it was reſcued by Mr. Von Humboldt, who has given an intereſting account of it, which is rendered ſtill more valuable by the chemical analyſis made of this ſubſtance by Fourcroy, Vauquelin, and Klaproth, to whom that celebrated traveller had communicated ſpecimens of it. The following contribution towards the hiſtory of the guano is taken from a letter written to Mr. Klaproth by Mr. Von Humboldt.

The word *huana* (the European always confound the ſyllable *hua* with that of *gua*, and *u* with *o*) ſignifies, in the language of the Incas, *dung* for manuring: the verb *to manure* being *huanunchani*. All the Aborigines of Peru were of opinion that this ſubſtance is birds'-dung; which was, however, doubted by many of the Spaniards.

It is worth remarking that all the Guano-iſlands and rocks are ſituated between the 13th and 21ſt degree of S. lat.; and yet the number of cormorants, flamingos, and cranes appears to be equally conſiderable in the iſlands ſituated farther towards the north or ſouth. Near the town of Arica, the ſmall iſland called Iſla di Guano, emits ſuch an intolerable ſtench, that (as has been already obſerved by father Feuillée) ſhips are often prevented from approaching it. In

Arica large magazines are erected alongside the shore for the reception of the guano. If we consider that, ever since the twelfth, or at least the thirteenth century, it has been customary in Peru to manure with this substance; that many millions of cubic feet have been strewed over the sandy parts of Peru (and indeed the possibility of practising agriculture along the sea-coast depends entirely on this precious material); and farther, that the guano still continues to be furnished in large quantities, and that the experience of the present generation appears to prove that those birds, on one of the islands, will scarcely produce a ship-load of dung in a great number of years; if we consider all this, we cannot refrain from being astonished at the long series of centuries, or the vast number of birds, that must have been required to accumulate those immense strata of guano.

The fresh birds' dung seen on the rocks about Huaura, and in other parts of the American coast in the South sea, forms a thin whitish crust, perfectly different in appearance from the brownish-yellow guano.

Though we can no longer hesitate to consider also the guano as dung of birds, yet it may be asked, has it originated on the same islands where it is now found, or has it been accumulated there by some revolution of the earth? Does it point back to an era when the deluged globe was provided with a greater number of aquatic birds than at the present time, in the same manner as the coal-formation refers us back to a vastly luxuriant vegetation? Or was the guano formed under circumstances perfectly similar to those now existing, and was nothing required to produce such immense stratification but a long succession of ages? A long residence on the rocks and islands of the Peruvian coast, and attentive observation of the quantity of dung deposited at present by many thousand cormorants and flamingos in the space of one year, are the means which may, perhaps, at a future period, enable us to answer these questions. But it may be asked, what is to become of Peruvian agriculture, and what of the population of the coast, when the exhausted Guano island shall no longer yield this manure?

Though the offensive effluvia of the guano produce nausea and sternutation in those who pass a *guanero* (a vessel loaded with this substance) on the sea, it is nevertheless true that the health of the crew of those vessels is not in the least affected by it. Humboldt observed in most of these people a healthy blooming complexion; but he adds, that ten or twelve years practice in this uncleanly but profitable trade, had done much to inure them to the otherwise deleterious effects of those fœtid exhalations. Notwithstanding this, the inhabitants of Arica impute the frequent intermittent fevers of that part of the coast to the stench produced by the guano.

Ulloa (in his Relacion del Viage a la Amer. Merid. iii. p. 127.) says, that when the depth is considered in which the guano is dug, it appears probable that it is an earth, although the smell might be considered as against this opinion; and he is inclined to suppose that a considerable portion of earth is mixed with the birds' dung. Frezier, who examined the Peruvian coast in 1712 and 1714, also visited the harbour of Arica, and the island Iquique, to the south of it. On the latter island the guano was dug up by negroes. Frezier confesses that he is at a loss to explain how such immense masses can have been produced by birds, but affirms that feathers of birds have been found at a considerable depth. (Frezier Voy. dans la Mer de Sud. p. 133.)

In the neighbourhood of Arica, where the crop of pepper (Capsicum baccatum) is valued at from 3 to 400,000 dollars a year, each plant is manured three times every season with guano, *viz.* at the periods of taking root, flowering, and producing the fruit.

Under the government of the Incas, the guano was considered as an important object of political economy. It was prohibited, under pain of death, to destroy any of the birds on the Guano islands, each of which had its inspectors, and was divided into departments. From Arica to Chancay, a tract of 200 leagues in length, no other manure was made use of than guano (Garcilasso, Hist. de las Yncas, i. p. 184.) This great care accounts in some measure for the vast increase of the guano. But those wise regulations have long been abolished: at present the guano is dug for without regularity and at all seasons.

In an account of the guano, given by the same celebrated naturalist to Messrs. Fourcroy and Vauquelin, mention is made of a few other circumstances relative to that substance, that should not be omitted in this place. The guano, says Mr. Humboldt, is found not only in the Chinche islands, near Piseo, but it exists also on the parts of the coast and its isles situated more to the south, at Ilo, Iza, and Arica. The inhabitants of Chancay, who trade in this article, go to the Chinche islands, and return in twenty days. Each boat takes a cargo of from 1500 to 2000 cubic feet of the guano. A vanega is worth four livres at Chancay, and fifteen livres at Arica.

The strata in which the guano is disposed are from fifty to sixty feet in thickness, and they are worked in the same manner as the iron ochre mines. It is an excellent manure for the Indian corn or maize; but if too much of it be applied, the root is burnt and destroyed by it.

When exposed to the fire the brownish yellow colour of the guano is converted into black; it gives out white fumes, and the smell of empyreumatic ammonia. Water dissolves part of it, becomes thereby of a reddish colour, and adopts an acid taste. Potassa dissolves much more of it than water; the solution is of a deep brown colour, and is produced under an abundant developement of ammonia. The result of the chemical analysis, made by Fourcroy and Vauquelin, is that the principal constituent part is concrete *uric acid*.

Klaproth has since obtained nearly the same results as the French chemists; his experiments prove that the essential component parts of the guano, exclusive of the admixed sand, are ammoniacal uric acid, phosphate of lime, oxalate of lime, and a residuum of animal colla, or similar animal inflammable component part. The oxalic acid, however, Klaproth supposes not to be an original constituent part of the guano, but the product of a long-continued action of the atmospheric oxygen of the uric acid; an opinion founded on his own experience respecting the easy conversion of uric into oxalic acid, by the application of nitric and oxygenated muriatic acid. The proportion of the constituent parts is as follows.

Ammoniacal uric acid	-	16
Phosphate of lime	-	10
Oxalate of lime	- -	12.75
Silica	- - - -	4
Muriate of soda	- -	0.50
Sandy admixture	- -	28
		71.25
Water, inflammable animal remains, and loss		28.75
		100 Klapr. Beitr. vol. iv.

GUANOBUCOA, in *Geography*, a town of the iſland of Cuba; 8 miles S. of the Havannah.

GUANTA, a town of Peru, in the biſhopric of Guamanga, capital of a juriſdiction of the ſame name; 20 miles N. of Guamanga. N. lat. 12° 30′. W. long. 74° 16′.

GUANTAJAYA, a town of Peru, in the province of Arica. In this intendancy, with its dependancy of Tacna, one mine of gold and twenty of ſilver were wrought in 1791. At the ſame time no leſs a number than nineteen of the former metal had been abandoned. This was alſo the caſe with 30 mines of ſilver. The celebrated mine of Guantajeya, or Huantajaya, in the neighbourhood of Tacna, is a recent diſcovery. It is ſingularly ſituated in a ſandy plain, at a conſiderable diſtance from the mountains; and ſome of the veins are ſaid to be ſo rich, that they are cut with a chiſſel. S lat. 20° 45′. W. long. 70° 10′.

GUANTANAMO Bay, a bay on the S. coaſt of the iſland of Cuba. N. lat. 20° 12′. W. long. 74° 47′.

GUANVACANA, a town of Peru, in the dioceſe of Guamanga; 80 miles E.S.E. of Guamanga.

GUANUCO, or Huanuco, a town of Peru, and capital of a juriſdiction which commences about 120 miles N.E. of Lima. This town was founded in 1539, under the name of Leon de Guanuco; the firſt inhabitants being thoſe, who, in the broils of the Pizarros and Amagros, followed the royal party. It was formerly a conſiderable city, but is now, according to Alcedo, a mean village on the royal road of the Incas, with ruins of a royal palace and temple of the ſun. The climate is for the moſt part pure and mild, the ſoil fertile, the fruits excellent, and the conſerves much eſteemed at Lima. The church, three convents, and the deſcendants of the conquerors are ſunk into great poverty; 120 miles N.E. of Lima. S. lat. 9° 59′. W. long. 75° 56′.

Guanuco *River*. See Gualaga.

GUANUCOS, a river of Mexico, which runs into the Golfo Dolce at its mouth.

GUAPERVA, in *Ichthyology*. See Chætodon *Arcuatus*, and *Lanceolatus*. See alſo Lophius *Hiſtrio*.

Guaperva is alſo the name of ſeveral ſpecies of *Baliſtes*: thus, the guaperva hiſtrix of Willughby is the baliſtes aculeatus; the guaperva peixe-porco of Marcgrave, &c. or guaperva maxima caudata of Willughby and Ray, is the baliſtes vetula; the guaperva lata ad caudam ſtriata Liſteri is the baliſtes ringens; and the guaperva lata, cauda forcipata, &c. of Willughby is the baliſtes forcipatus.

GUAPURIUM, in *Botany*, from its Peruvian name *Guapuru*, a word too barbarous to be received into a regular ſyſtem of botany, and therefore, no doubt, one of thoſe which Juſſieu himſelf tells us in his introduction, p. 24, note *c*, he adopts only for a time, till the genera to which they belong are finally aſcertained. Juſſ. 324. Claſs and order, *Icoſandria Monogynia*. Nat. Ord. *Myrti*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, four-cleft. *Cor.* Petals four. *Stam.* Filaments numerous; anthers roundiſh. *Piſt.* .... *Peric.* Berry globular, umbilicated, crowned with the calyx, pulpy within. *Seeds* from two to four.

A *ſhrub*; the *leaves* of its principal branches deciduous, of the ultimate ones oppoſite, ſimple, from three to ſix pair, as if abruptly pinnate, ſprinkled with pellucid dots. *Flowers* in tufts from the cracked bark of the leafleſs branches. The habit is that of a *Plinia*, but the germen is not ſuperior.—Such is the account given by Juſſieu, from his uncle's manuſcripts, and the inſpection of a dried ſpecimen. The original *Plinia* itſelf is ſo obſcure, and there is ſo much reaſon to ſuſpect a miſtake in Plumier's repreſentation of the ſituation of the germen, that it is impoſſible to ſay whether this plant be of the ſame genus or not.

GUARA, in *Ornithology*, the name of a Braſilian bird, called by Cluſius *numenius Indicus*, or the *Indian curlew*. See Tantalus *Rubr*.

Guara, in *Ichthyology*. See Scomber *Cordyla*.

GUARACAPEMA, a name uſed by ſome for the fiſh more uſually called the *dorado*. See Coryphæna *Equiſelis*.

GUARACAYO, in *Geography*, a town of S. America, in the province of Quito; 6 miles N.N.E. of Jaen.

GUARACHIRI, a town of Peru, and capital of a juriſdiction in the audience of Lima, commencing at the mountains, about ſix leagues E. of Lima. The vallies and lower grounds are the only inhabited parts, and theſe, being very fertile, produce wheat, barley, maize, and other grain in great abundance. Its mountains have ſilver mines, but few of them are wrought; 50 miles E. of Lima. S. lat. 11° 55′. W. long. 76° 18′.

GUARANIA, a province of the viceroyalty of Buenos Ayres, ſo called from the Guaranis, a tribe of Indian inhabitants, who occupy about 30 villages, from the river Tabiquari, in Paraguay, to the frontiers of Buenos Ayres, being moſtly to the E. of the river Parana: the eaſtern borders of the Guaranis extend along Brazil, and on the W. they border on Paraguay, Corrientes, and Santa Fé. As ſoon as a Guarano Indian dies, his companions take up the corpſe, and throw it into the Oronoko, tied to a cord which they faſten to a tree. On the following day they drag out the corpſe, when it is found to be a ſkeleton, perfectly clean and white, ſtripped of the fleſh which has been devoured by fiſh. They then diſjoint the bones, and lay them up curiouſly in a baſket, which they hang from the roof of the houſe.

GUARANTEE, or Warrantee, in *Law*, a term relative to *warrant*, or *warranter*; properly ſignifying him whom the warranter undertakes to indemnify or ſecure from damage.

Guarantee, is more frequently uſed for a warranter, or a perſon who undertakes and obliges himſelf to ſee a ſecond perſon perform what he has ſtipulated to the third. See Warranty.

GUARANTHARA, in *Geography*, a river of the Brazil, which runs into the Atlantic, S. lat. 7° 20′. W. long. 34° 25′.

GUARANTY, in *Politics*, an engagement of mediatorial or neutral ſtates, whereby they pledge their faith, that the articles of a particular treaty ſhall be inviolably obſerved on both ſides.

This engagement implies, that the guarantees are obliged to aſſiſt the party invaded contrary to the treaty, againſt the injurious aggreſſor; but not if the war is occaſioned by any other cauſes than the violation of the articles of peace. Puffendorf, Law of Nature and Nations, book viii. ch. 8. § 7.

The ancient lords were obliged to guaranty the lands of their vaſſals, *i.e.* to defend them againſt their enemies; otherwiſe they loſt their fee, and their vaſſals were no longer bound to do them homage and ſervice. Kings alone did not forfeit their fiefs by not guarantying them; and yet we read, that Borel, count of Barcelona, threatened the king of France, Hugh Capet, to ſwear fealty to the Saracens, in caſe he did not guaranty him; and under Lewis the Young, the count of Champagne did homage to the emperor, on the like account.

To guaranty a fee, had likewiſe another meaning; being uſed to denote that where a fee was divided between the eldeſt ſon and the younger, the eldeſt did homage to the lord,

lord, both for himſelf and all the reſt; and by that homage guarantied the whole.

GUARAPIRANGA, in *Geography*, a town of Brazil, in the government of Minas Geracs; 40 miles S.E. of Villarica.

GUARAPO, an intoxicating liquor made from the fermentation of coarſe ſugar and water. It is in general uſe throughout Terra Firma. The Indians and negroes prefer it to the beſt wine. Thoſe who ſell it muſt have a licence from the farmer of the tax, for which they pay. The proceeds from farming the guarapos, and cock-fights, are appropriated to the maintenance of the hoſpital of St. Lazarus, at Caraccas.

GUARAPUCU, in *Ichthyology*. See SCOMBER *Thynnus*.

GUARAQUAÇU, in *Geography*, a river of the Brazil, which runs into the Atlantic, S. lat. 9° 36'. W. long. 35° 16'.

GUARA-TEREBA, in *Ichthyology*. See SCOMBER *Cerdyla*.

GUARATIBA, in *Geography*, a river of Brazil, which runs into the Atlantic, S. lat. 7 20'.

GUARAUNA, in *Ornithology*. See SCOLOPAX *Guarauna*.

GUARD, or GARD, in its general ſenſe, implies defence, cuſtody, or conſervation, of any thing; the act of obſerving what paſſes, to prevent ſurprize; or the care and precaution taken to hinder any thing's being done contrary to the intention and deſire of another.

The word is formed of the French *garde*, and that of the corrupt Latin *warda*, and that of the German *wahren*, *to keep, to defend*.

GUARD is alſo uſed in a figurative ſenſe, for the act or ſervice of guarding, and the perſons appointed for that purpoſe.

Thus we ſay, to be upon guard, to ſet the guard, mount the guard, to diſmount the guard, to relieve the guard, to change the guard, the officer or ſerjeant of the guard; alſo, a ſtrong guard, an attempt on the guard, &c.

So, again, thoſe to whom the king commits the ſafety of his perſon, are called his *guard*, *life-guard*, *body-guard*. And ſo thoſe who have had the education and guardianſhip of infants, or idiots, are called their *guards* or *wards*.

GUARD, or *Gard*, is alſo applied to a writ relating to the office of ward; whereof there are three kinds; one called *droit de garde*; the ſecond, *ejectment de garde*; the third, *raviſhment de garde*. See GUARDIAN.

GUARD, in the *Military Senſe*, is properly the duty or ſervice done by the ſoldiers, to ſecure the army, or place, from the attempts and ſurpriſes of an enemy. In garriſon the guards are relieved every day; ſo that every ſoldier mounts guard once every three or four days in times of peace, and much oftener in time of war. Of this there are divers kinds: as,

GUARD, *Advanced*, a party of horſe or foot, which marches before a corps, to give notice of approaching danger. See ADVANCE *guard*.

GUARD, *Artillery*, is a detachment from the army to ſecure the artillery when in the field. Their "corps de garde" is in the front of the ARTILLERY *park* (which ſee), and their ſentries diſperſed round it. This is generally a 48 hours' guard; and upon a march this guard marches in the front and rear of the artillery, and have it in charge to leave nothing behind. If a gun or waggon breaks down, the officer that commands the guard is to leave a ſufficient number of men to aſſiſt the gunners and matroſſes in getting it up again.

GUARD, *Artillery quarter*, is frequently a non-commiſſioned officer's guard from the royal regiment of artillery, whoſe *corps de garde* is always in the front of their encampment.

GUARD, *Artillery rear*, conſiſts of a corporal and ſix men, poſted in the rear of the park. See ARTILLERY *park*.

GUARD, *Baggage*, is always an officer's guard, who has the care of the baggage on a march.

GUARD-*boat*, in *Sea Language*, a boat appointed to row the rounds among the ſhips of war which are laid up in any harbour, &c. to obſerve that their officers keep a good look-out, calling to the guard-boat as ſhe paſſes, and not ſuffering her crew to come aboard, without having previouſly communicated the watch-word of the night.

GUARDS, *Camp*, are of two ſorts; the one ſerve to maintain good order within the camp, (ſee CAMP,) and the other, which are ſtationed without the camp, ſerve to cover and ſecure it againſt the enemy. They are formed both of infantry and cavalry; and ſhould conſiſt, as the occaſion requires, of the eighth part, or third part, or even of half the army, when an attack is apprehended. The cavalry guards are removed farther from the main army than the infantry; but not ſo far as to endanger their being cut off. Theſe guards have generally a day poſt and a night poſt; the latter of which is ſeldom more than four or five hundred paces from the camp: the guards of infantry are generally fixed, except thoſe that are to ſupport and protect the cavalry guards, and to cover the forage grounds.

GUARD, or GARDE, *Corps de*. See CORPS.

GUARD, *Counter*, in *Fortification*. See COUNTER-*guard*.

GUARD, *Forrage*. See FORRAGE.

GUARD, *Grand*, conſiſts of three or four ſquadrons of horſe commanded by a field officer, and poſted before the camp on the right and left wing towards the enemy, for the ſecurity of the camp.

GUARD-*irons*, in a *Ship*, are certain curved or arched bars of iron, placed over the ornamental figures on a ſhip's head or quarter, to defend them from the impreſſion of ſome other ſhip, when they lie cloſe to or rub againſt each other.

GUARD, *Main*, is that from which all the other guards are detached. Thoſe who are to mount the main guard, meet at the reſpective private parades, and from thence they go to the general parade; where, after the whole guard is drawn up, the ſmall guards are detached to their reſpective poſts; and then the ſubaltern officers draw lots for their guards, who are all commanded by the captain of the main guard. This guard mounts in garriſon at different hours, according to the pleaſure of the governor.

GUARDS, *Ordinary*, are ſuch as are fixed during the campaign, or in garriſon towns, and which are relieved daily; whereas *extraordinary* guards, or detachments, are ſuch as are only commanded on particular occaſions; either for the further ſecurity of the camp, to cover the foragers, or for convoys, eſcorts, or expeditions.

GUARDS, *Mounting*. All guards are to parade with ſhouldered arms, and unfixed bayonets, without any intervals between them, the ranks open, and the ſerjeants with pikes carried. The officers with their ſwords drawn, and non-commiſſioned officers commanding guards, to be formed about 40 paces in front of the centre, in two ranks, facing the line, where they are to receive the old parole and ſuch orders as may be given them.

The major or commanding officer will give the word of command—

"Officers and non-commiſſioned officers, outward face!—Take poſt in front of your reſpective guards!—Quick, March!"

As ſoon as they have taken poſt, fronting their reſpective guards, the word of command will be given—

"Officers

"Officers and non-commiſſioned officers—to your guards —March!—Halt!—Front!"

"Officers and non-commiſſioned officers, inſpect your guards!"

The ſeveral officers and non-commiſſioned officers will then inſpect their guards, as quick as poſſible. When there is a captain's guard, each officer is to take a rank, the ſerjeants accompanying them.

As ſoon as the inſpection is over, the adjutant will go down the line and receive the report of each guard; the officers return to their poſts; and the major, or commanding officer, will then—

"Order arms!—Fix bayonets!—and Shoulder!"

When the colours are brought on the parade, the troop is beat; and the drummer's call on the right.

The captain will face inwards, and the lieutenant and enſign will face to the right, and march, *quick time*, to the head of the grenadiers. The captain goes to the head of the right of his remaining men. The field officer then orders the grenadiers to cloſe their ranks, and to march off in *quick time*, the lieutenant being three paces advanced in front of his men, and the enſign one. The colours will be received as uſual. And the grenadiers, on their arrival on the left flank of the guards, will file at the *ordinary time*, through the ranks; the lieutenant, and the colours, in front of the front rank. The guards are to march off at the *ordinary time*, and by diviſions, taking care, that when they open their ranks, the front rank of each keeps its exact diſtance from the front rank preceding it. When there are more officers than one belonging to the ſame guard, the ſecond in rank is to take poſt, and to march paſt the commanding officer on the parade, at the head of the laſt diviſion, inſtead of being in the rear of it. When there is an officer, ſenior to the field officer of the day, on the parade, the guards are to march by and ſalute him: the field officer of the day, in that caſe, marching at their head.

GUARDS, *Out*, may lead us to conſider *out-poſts*, *advanced picquets*, and *detachments*. The duty of out-poſts, &c. as ſtated by the laſt printed regulations, is chiefly confined to light troops, who are occaſionally aſſiſted and relieved by the line. In that caſe, they are always under the direction of ſome general. But when it becomes neceſſary to perform this duty from the line, the out-poſts fall under the command of the general officers of the day, unleſs ſome particular officer be put in orders for that ſpecific command. All outguards march off without trumpets ſounding, or drums beating. They pay no compliments of any kind; neither do their ſentries take any complimentary notice of officers paſſing near their poſts. No guards are to preſume to ſtop any perſons coming to camp with proviſions (unleſs they be particularly ordered ſo to do), and are on no account to exact or receive any thing for their free paſſage.

Any officer, trumpeter, or other perſon, who comes from the enemy's camp, is to be ſecured by the firſt guard he arrives at, till the commander in chief's, or the general's pleaſure is known. When a deſerter comes in from the enemy, the officer commanding the poſt, or guard, at which he arrives, is immediately to ſend him under a proper eſcort, (without permitting him to be delayed or examined, or any queſtions aſked him) to the officer commanding the out-poſts, who, after enquiring whether he brings any intelligence immediately relating to his own poſt, will forward him to head-quarters.

The ſentries on the outpoſts are always to be double. No officers, ſoldiers, or followers of the camp, are on any account to be ſuffered to paſs the outpoſts, unleſs they are on duty, or preſent a regular paſs from head-quarters.

The men on advanced picquets are to carry their proviſions with them, ready cooked, when circumſtances will permit. The cavalry to carry ſufficient forage for the time they are to be out.

It is the duty of officers on all guards to inſpect every relief of ſentries, both when they go on, and come off their poſts; to call the rolls frequently, and by every means in their power to keep the men under their command in the moſt perfect ſtate of vigilance and preparation.

Officers commanding outpoſts are to ſend guides, or orderly men, to the major of brigade of the day, or to the brigade-major of their own brigades, as circumſtances require, in order to conduct the new guards, and to carry ſuch orders as may be neceſſary.

When the army is on a march, the officers muſt apprize the brigade-majors of the ſituation of their poſts, as ſoon as they arrive at them. All detachments of brigades, which are ordered to march *immediately*, are to be taken from the picquets, and replaced directly from the line.

Whenever detachments exceed 200 men, or upwards, a ſurgeon or ſurgeon's mate is to be ſent from the corps of the officer who commands. On particular duties, the attendance of a ſurgeon or mate may be requiſite with ſmaller detachments. Detachments of cavalry, of 50 or upwards, will be attended by a farrier.

As ſoon as an officer commanding an outpoſt, or advanced picquet, (whether of cavalry or infantry,) arrives on his ground, he muſt endeavour to make himſelf maſter of his ſituation, by carefully examining, not only the ſpace he actually occupies, but the heights within muſket-ſhot; the roads and paths leading to or near his poſt, aſcertaining their breadth and practicability for cavalry and cannon. He ſhould examine the hollow ways that cover the approach of an enemy; and, in ſhort, conſider all the points from which he is moſt likely to be attacked, either by cavalry or infantry. He will, by theſe means, be enabled to take meaſures to prevent the poſſibility of being ſurprized; and ſhould he be attacked during the night, from the previous knowledge he has obtained of the ground, he will at once form a juſt eſtimate of the nature of the attack, and make his arrangements for defence with promptitude and deciſion. In order to convey the ſame alacrity to his men, and to prepare the moſt unexperienced for ſudden and unexpected attacks, an officer upon an outpoſt will do well to put them upon the alert, by ſkilfully occaſioning falſe alarms. But theſe muſt not be often repeated, nor when practiſed be made known to his men as having proceeded from himſelf; ſince ſupineneſs and inactivity might by degrees be the conſequences of ſuch a diſcovery.

An intelligent officer upon an outpoſt, even unprovided with entrenching tools, will materially ſtrengthen his poſt, when the unobſerver would remain inactive. A tree felled with judgment; bruſhwood cut to a certain diſtance; pointed ſtakes, about breaſt high, placed on the points moſt aſſailable by an enemy, may be attended with the greateſt advantages, and can be effected with the common hatchets, which the men carry to cut fire-wood. In ſhort, every impediment which an officer, acting on the defenſive, can throw in an enemy's way, ought to be ſcrupulouſly attended to. Independently, therefore, of the means which he adopts for the immediate protection of his poſts, he muſt look beyond that point; and as nothing checks the ardour of troops more than an unexpected obſtacle, within an hundred yards, more or leſs, of the place attacked, he muſt, on his arrival at the outpoſt, throw up ſome temporary impediment at that diſtance. See General Regulations 34 to 37.

GUARD, *Picquet*, is a number of horſe and foot, who keep themſelves always in readineſs in caſe of an alarm; the horſes being generally ſaddled, and the riders booted. The foot draw up at the head of the battalion at the beating of the tattoo, but afterwards return to their tents, where they remain in readineſs to march on any ſudden alarm.

This guard is to make reſiſtance in caſe of an attack, till the army can get ready.

GUARD, *Port*, a guard detached from the main guard. All officers on port, or detached guards, are to ſend a report, night and morning, to the captain of the main guard, and at all other times, when any thing extraordinary occurs. Thoſe who command at the ports are to draw up the bridges, on the approach of any body of armed men, of which they are to give notice to the officer of the main guard, and not to ſuffer any of them to come into the garriſon, without leave from the governor or commander.

GUARD, *Provoſt*, is always an officer's guard that attends the provoſt in his rounds, to prevent deſertion, marauding, rioting, &c.

GUARD, *Quarter*, is a ſmall guard commanded by a ſub-altern officer, poſted in the front of each battalion, about two hundred and twenty-two feet before the front of the regiment.

GUARD-*Rails*, are ſtrong rails of wood bolted on to piles, juſt above the level of the water, at the head and tail of the locks on canals, and projecting before the wing-walls, for guiding the boats into the locks, and prevent their ſtriking the walls.

GUARD, *Rear*, is that part of the army which brings up the rear on a march: the rear guard of a party is frequently eight or ten horſe, about five hundred paces behind the party. Hence the advance guard going out on a party, forms the rear guard in their retreat.

Rear Guard is alſo a corporal's guard placed in the rear of a regiment, to keep order in that part of the camp.

GUARD, *To Relieve*. See RELIEVE.

GUARD *Rooms* of cavalry and infantry are allowed a water-bucket, candleſtick, tin can for beer, and drinking horns: they are alſo allowed fire-irons and coal-tray, from Sept. 1 to May 1, when they are to be taken into ſtore. The rooms of the quarter-maſters and ſerjeants of cavalry, and the ſerjeant-major and quarter-maſter ſerjeant of infantry, are to be furniſhed with the neceſſary bedding and utenſils in the ſame manner as is allowed to the ſoldiers' rooms.

GUARD, *Safe*. See SAFE *Guard*.

GUARD-*Ship*. See *Guard*-SHIP.

GUARD, *Standard*, is a ſmall guard under a corporal, out of each regiment of horſe, who mount on foot in the front of each regiment, at the diſtance of twenty feet from the ſtreets, oppoſite to the main ſtreet.

GUARD, *Trench*, conſiſts of three, four, or ſix battalions, according to the occaſion, which mount in the time of a ſiege, in order to oppoſe the beſieged when they ſally out, protect the workmen, &c.

GUARD, *Turn out the*, is a phraſe uſed when it is neceſſary for the guard to form for the purpoſe of receiving a general or commanding officer; on the approach of an armed party; on the beat of drum, or ſound of trumpet, or any alarm.

GUARD, *Van*, is the ſame with the front of an army. See ADVANCE *Guard*, and *Advance* GUARD, above.

GUARD is more particularly underſtood of a ſoldier, as a muſqueteer, archer, or the like, detached from a company, or corps, to protect, detain, or ſecure, any perſon, or to ſurvey his actions.

GUARDS is alſo underſtood of the troops, or companies, kept to guard the king; called alſo *royal guards*, *life guards*, *gardes du corps*, &c.

There are alſo uſually bodies of guards to wait on the princes of the blood, in the ſame capacity.

The guards are diſtinguiſhed into *horſe*, *foot*, *grenadiers*, and *yeomen*.

GUARDS, *Horſe-Grenadier*, were divided into two troops, called the 1ſt and 2d troops of horſe-grenadier guards. The firſt troop was raiſed in the year 1693, and the command given to lieutenant-general Cholmondeley; the 2d in 1702, and the command given to lord Forbes. Each troop has a colonel, lieutenant-colonel, one guidon, or major, three exempts and captains, three lieutenants, one adjutant, three cornets, and ſixty private men.

GUARDS, *Life*. In conſequence of the reduction of the horſe-grenadier guards, two regiments have been raiſed for the expreſs purpoſe of guarding the metropolis, and of eſcorting his majeſty. They are generally called the 1ſt and 2d life-guards. Each regiment conſiſts of ſix troops of 53, and one kettle-drum.

GUARDS, *Royal Regiment of Horſe*, is commonly called the "Oxford Blues," from having been originally raiſed by the earl of Oxford, and conſiſts of nine troops. The quarter-maſter belonging to this corps is an exception to the general regulations that affect the quarter-maſters of all cavalry regiments. The latter hold their commiſſions by warrants, but the former has the ſign-manual to his appointment.

GUARDS, *Yeomen of the*, firſt raiſed by king Henry VII. in the year 1485, are a kind of foot guards to the king's perſon, and are generally called by a nick-name beef-eaters. They were anciently 250 men of the firſt rank under gentry, and of a larger ſtature than ordinary, each being required to be ſix feet high. At preſent there are but 100 on conſtant duty, and 70 more not on duty; and when any one of the 100 dies, his place is ſupplied out of the 70. They are dreſſed after the faſhion of king Henry VIII.'s time. Their firſt commander, or captain, was the earl of Oxford, and their pay is 2*s*. 6*d*. *per* day.

GUARDS, *The Foot*, are appointed for the guard of his majeſty and his palace, and for general ſervice: they are diſtinguiſhed by regiments: of which there are three, called the 1ſt, &c. regiment of foot guards. They were raiſed in the year 1660: the firſt regiment is commanded by one colonel, one lieutenant-colonel, three majors, twenty-ſeven captains, one captain-lieutenant, ſixty-two lieutenants, twenty-four enſigns, and three adjutants; and it conſiſts of three battalions. The 2d regiment, or Cold-ſtream, has one colonel, one lieutenant-colonel, two majors, ſixteen captains, one captain-lieutenant, forty-two lieutenants, fourteen enſigns, and two adjutants; and conſiſts of two battalions. The third regiment is the ſame as the ſecond.

Guards, no doubt, are as ancient as monarchy: the remoteſt antiquity affords inſtances of them.

The Roman emperors had for their guard the prætorian cohorts, eſtabliſhed by Auguſtus, as Dion and Suetonius relate: thoſe of the emperors of Conſtantinople were called *buccellarii*.

Captain, colonel, brigadier, exempt of the guards, &c. See CAPTAIN, COLONEL, BRIGADIER, YEOMAN, &c.

The *Scotch guard* was firſt eſtabliſhed in France by Charles VII. who choſe himſelf a guard out of ſuch Scots as were ſent by the earls of Buchan, Douglas, and other Scotch lords, to drive out the Engliſh.

GUARDS, *Prætorian*. See PRÆTORIAN.

GUARDS, *White*. See SCHOLARES.

GUARD, in *Fencing*, an action or poſture, proper to defend or

or ſcreen the body from the efforts or attacks of an enemy's ſword, or to execute any offenſive movements againſt him.

Some have reckoned four, and others five or ſix general guards of the ſword; to conceive which, it has been uſeful to imagine a circle drawn on an upright wall, and divided into four cardinal points, *viz.* top, bottom, right, and left.

Now, when the point of the ſword is directed to the bottom point of the circle, and conſequently, the head of the ſword tilted up to the top point, with the body inclining forwards, this is called *prime*, or the *firſt guard*. The *ſecond guard*, which ſome improperly call the *third*, is when the point of the ſword is directed to the right or ſecond part of the ſame circle, a quadrant diſtant from the firſt, with the fort of the ſword turned to the right, and the body raiſed proportionably. *Tierce*, or the *third guard*, is performed by directing the ſword's point to the uppermoſt point of the ſame circle diametrically oppoſite to that of prime; in which caſe the body, arm, and ſword, are in their natural diſpoſition, being the mean between the extremes of their motion. *Quart*, *Carte*, or the *fourth guard*, is when the point of the ſword is directed to the fourth point of the circle, deſcending to the right as far as one fourth of tierce, with the external ſide of the arm and the flat of the ſword turned towards the ground and the body out of the line to the right, and the fort of the ſword towards the line to the left. There is alſo a *quint*, or a kind of *fifth guard*, being the return of the point of the ſword on the right, after traverſing the circle to the point of the prime whence it had departed; and yet with a different diſpoſition of the body, arm, and ſword.

Theſe guards are alſo called, by the maſters, *figures* and *poſtures*; and the common centre of all their motions is to be in the ſhoulder.

In all theſe kinds of guards, there are high *advanced*, high *retired*, and high *intermediate guards*, when diſpoſed before the upper part of the body, either with the arm quite extended, quite withdrawn, or in a mean ſtate. *Mean advanced guard*, or ſimply *mean guard*, is when the ſword is diſpoſed before the middle part of the body. *Low advanced*, *retired*, or *intermediate guards*, are thoſe where the arm and ſword are advanced, withdrawn, or between the two extremes, before the lower part of the body.

Some will have prime the principal guard: others, quint: others, with better reaſon, tierce; becauſe it conſiſts of right lines, which are more eaſily defended than oblique ones, ſuch as thoſe of prime, ſecond, quart, and quint. By modern practice, only two guards are uſed in ſmall ſword play, *viz.* the guard of carte, and the guard of tierce, called the inſide and outſide guards. The one covers your body from a ſtraight inſide thruſt, by croſſing blades on that ſide, and the other covers you from a ſtraight outſide thruſt, by oppoſing the blade outwards. Guards are ſynonymous with engagements.

Mr. M'Arthur, having reduced the guard-poſtures to the two above-mentioned, gives the neceſſary inſtructions, in a conciſe but very perſpicuous and intelligible manner, for forming theſe two poſitions. His inſtructions are exemplified by appropriate figures, which cannot fail to aſſiſt the learner in apprehending them, and alſo in reducing them to practice. We profeſs neither to be teachers nor practitioners in the art of fencing; and we conceive, that little can be done by any ſyſtem of rules, however excellent, without correſponding exerciſe under the direction of a maſter. The reader, whom it may concern, will, we imagine, be induced by the following extract to recur to this ingenious author's "New and Compleat Treatiſe on the Theory and Practice of Fencing, &c." of which a new and reviſed edition was publiſhed in 1784; or to ſome other ſimilar treatiſe on the ſubject. The author begins with inſtructing the learner how to hold his ſword or foil well. For this purpoſe the hilt muſt be flat in the hand, ſo that the two edges may be nearly horizontal when the learner throws himſelf upon guard; the thumb being ſtretched along upon the upper flat part of the hilt, within half an inch of the ſhell or guard, and the pummel reſting under the wriſt. The ſword or foil being held in this manner, and the learner ſtanding upon his firſt poſition, ſimilar to what is called the third poſition in dancing; that is, with the right foot before the left, and the heel advanced near the buckle, is directed to throw himſelf upon the common guard of carte, by advancing his right foot about the diſtance of $1\frac{1}{2}$ foot in meaſure from the left, or at the diſtance of two lengths of his own foot from the heel of the other. The two heels ſhould be in the ſame ſtraight line. "Turn your wriſt," ſays the author, "in ſuch manner, that the nails may appear upwards. Your hand ſhould be on a line with the lower part of your breaſt; the arm not ſtretched, but a little bent and flexible, and the elbow inclined a little to the outſide. The point of your ſword or foil ſhould be about 15 degrees elevated, and nearly fixed on a line with the upper part of your adverſary's breaſt. The left arm, which is neceſſary to balance the body in its different movements, muſt be raiſed in a ſemi-circular manner, on a line with the forehead, the hand kept open in an eaſy manner, the thumb and firſt finger nearly meeting. Your body ſhould be totally ſideways, and your head turned towards the right, ſo as to keep ſight of your point: for it is evident, the leſs you expoſe the breadth of your body, by keeping it in a direct ſide poſture, the more difficulty there will be to touch you in aſſaults: your body, feet, arms, and ſhoulders ſhould be in the ſame ſtraight line: let the balance of your body reſt upon the left leg, by keeping the left knee bent and flexible, ſo as you may incline a little backwards. The right leg ſhould be kept eaſy on the ground, the knee alſo a little bent, and perpendicular to the point where your right heel reſts." The next point is to acquire the mode of advancing and retreating upon the carte guard, without varying the above-deſcribed poſition; "In order to advance with regularity, move the right foot with eaſe forward to the diſtance of more than a foot, making the left foot inſtantly follow to the ſame diſtance: theſe two movements muſt ſeem as one, by being comprehended in the ſame moment of time. Keep your body firm and ſteady upon guard while advancing. Let there be a pauſe of time, as long as a perſon might count over three, between every advance, always obſerving, after making five or ſix advances, that the diſtance and poſition of your guard is exactly the ſame with your primitive diſtance and poſition. The retreat on this guard is performed in the ſame manner as the advance thereon, only your left foot makes the firſt movement backwards, and your right follows in a line of direction at the ſame moment." "This is the firſt guard naturally taken by beginners, when entering upon aſſaults, and from it in general all the various thruſts and parades are thrown." The ſecond, or tierce-guard, is uſually practiſed in aſſaults by experienced fencers; and its poſition is the ſame with that of carte. "The hand only muſt be a little reverſed, ſo as that the nails, which were upwards in carte, muſt be half turned downwards, when in tierce-guard. The arm ſhould be a little ſtretched outwards in order to cover or ſecure the outſide. The point ſhould be in the ſame direction, as if on the other guard of carte; that is, fixed ſteadily, that your eye may perceive it oppoſite to the upper part of your adverſary's breaſt.

Advance and retreat on this guard with the ſame eaſe and regularity as is done in carte, agreeably to the inſtructions given in the firſt leſſon."

GUARDS, in *Aſtronomy*, is a name ſometimes applied to the two ſtars neareſt the pole; being in the hind-part of the chariot, at the tail of the Little Bear. See URSA *minor*.

GUARDS, in *Engineery*, are upright pieces of wood nailed on to the lock-gates of a canal, to keep the barges from ſtriking the planks on the gates.

GUARDA, or GUARDIA, in *Geography*, a ſtrong town of Portugal, in the province of Beira, and the ſee of a biſhop, ſuffragan of Liſbon; ſituated on Monte Eſtrella, near the ſource of the Mondego, containing a cathedral, four churches, two convents, an hoſpital, and about 2300 inhabitants; 67 miles E. of Coimbra. N. lat. 40° 21'. W. long. 6° 55'.

GUARDA, or *Guarda, La*, a town of Spain, on the W. coaſt of Gallicia; 14 miles W. S. W. of Tuy.

GUARDA, a town of the iſland of Cuba; 155 miles W. S. W. of Havanna.

GUARDAMAR, an inconſiderable ſea-port town of Spain, in the province of Valencia, ſituated at the mouth of the Segura, with a good harbour, and principally trading in the exportation of ſalt; 17 miles S. S. W. of Alicant. N. lat. 38° 7'. W. long. 0° 45'.

GUARDANT, or GARDANT, in *Heraldry*, a term applied to a beaſt when borne in a coat of arms, full faced, or with his face turned towards the ſpectator, and thus appearing in a poſture of guard or defence.

Heralds ſay, a lion is never ſo repreſented; but a leopard always.

GUARDIA, in *Geography*, the name of ſeveral towns of Naples, in the provinces of Calabria Citra, Baſilicata, and Principato Ultra.

GUARDIA, *La*, a town of Spain, in New Caſtile, ſituated in an elevated and ſalubrious tract, and containing about 3000 inhabitants, formerly ſtrong, but now decaying, and noted only for a manufacture of ſalt-petre; 22 miles E. S. E. of Toledo.

GUARDIA *Alferes*, a town of Naples, in the province of Moliſe, the ſee of a biſhop, ſuffragan of Benevento; 21 miles E. of Moliſe. N. lat. 41° 50'. E. long. 14° 50'.

GUARDIAN, or GARDIAN, is he to whom the charge, or cuſtody, of any perſon, or thing, is committed.

The notion of guardian angels is very ancient in the Eaſt. See ANGEL.

In the convents of Franciſcans, the officer is called *guardian*, who in the others is called *ſuperior*.

In the order of the Garter, the officer, who in other military orders is called *grand maſter*, is called the *ſovereign-guardian* of the order.

GUARDIAN, *Gardeyn*, in *Law*, is a perſon intruſted with the education, tuition, &c. of ſuch as are not of ſufficient diſcretion to guide themſelves, and their own affairs; as children and idiots.

The word *guardian*, with us, includes the offices both of the tutor and curator of the civilians: the tutor, for inſtance, had the government of a youth till he arrived at fourteen years of age; and the curator had the diſpoſition and ordering of his effects thenceforward till twenty-five years of age; or the charge of a lunatic, during his lunacy; all which purpoſes our guardian alone anſwers; though with regard to lunatics and idiots, theſe officers are commonly kept diſtinct. In other words, the tutor had the charge of the maintenance and education of the minor, and the curator, the care of his fortune; or, according to the language of the court of chancery, the former was the committee of the perſon, and the latter the committee of the eſtate.

There are ſeveral ſorts of guardians. The firſt are guardians by *nature, viz.* the father, and, in ſome caſes, the mother of the child: for if an eſtate be left to an infant, the father is, by common law, the guardian, and muſt account to his child for the profits (Co. Litt. 88.): and, with regard to daughters, it ſeems by conſtruction of 4 and 5 Ph. & Mar. cap. 8. that the father might by deed or will aſſign a guardian to any woman-child, under the age of ſixteen; and if none be aſſigned, the mother ſhall in this caſe be guardian. (3 Rep. 39.) The ſecond ſort are guardians for *nurture* (Co. Litt. 88.), which are, of courſe, the father and mother, till the infant attains the age of fourteen years (Moor. 738. 3 Rep. 38.); and in default of father or mother, the ordinary uſually aſſigns ſome diſcreet perſon to take care of the infant's perſonal eſtate, and to provide for his maintenance and education. (2 Jones. 90. 2 Lee. 163.) There are alſo guardians in *ſocage*, who are alſo called guardians by the *common law*: theſe take place only when the minor is entitled to ſome eſtate in lands, and then, by the common law, the guardianſhip devolves upon the next of kin, to whom the inheritance cannot poſſibly deſcend. (Litt. § 123.) Theſe guardians continue only till the minor is fourteen years of age; when he is preſumed to have diſcretion ſo far as to chooſe his own guardian.

But the ancient law relating to guardians is much altered by ſtat. 12 Car. II. cap. 24, which ordains, that "where any perſon has a child under the age of twenty-one years and unmarried at the time of his death, it ſhall be lawful for the father of the child, whether born at the time of his deceaſe, or yet in ventre de ſa mere, either by deed, or will, to diſpoſe of the cuſtody and tuition of ſuch child while under age, or for any leſſer time, to any perſon, popiſh recuſants excepted; which diſpoſition ſhall be good againſt all perſons claiming ſuch child as guardian in ſocage, or otherwiſe." Theſe are called guardians by *ſtatute*, or *teſtamentary* guardians. "And in caſe the father appoint no guardian, the ordinary may appoint one to look to his goods and chattels till the age of fourteen; at which time the child may chooſe a guardian himſelf; and for his lands, the next of kin on that ſide by which the lands deſcend may be guardian, as heretofore in caſe of a tenure in ſocage." There are alſo ſpecial guardians by *cuſtom* of London, and other places.

The guardian, when his ward comes of age, is bound to give him an account of all which he has tranſacted on his behalf, and muſt anſwer for all loſſes incurred by his wilful default or negligence. To prevent conteſts, the guardians of large eſtates apply to and act under the direction of the court of chancery, accounting annually before the officers of that court: for the lord chancellor, by right derived from the crown, is the general and ſupreme guardian of all infants, as well as idiots and lunatics. The court of chancery may, and ſometimes does remove a guardian who abuſes his truſt, and appoints another in his room. 1 Sid. 424. 1 P. Will. 703.

GUARDIAN, in *Chivalry*, was an office which formerly belonged to the feodal lord, in virtue of his wardſhip of an heir-male, under the age of twenty-one, and of a female under fourteen. This wardſhip conſiſted in having the cuſtody of the body and lands of ſuch heir, without any account of the profits till the age of twenty-one in males, and ſixteen in females. Theſe profits were claimed in lieu of knight-ſervice, which the male was ſuppoſed capable of rendering at twenty-one, and the female by her huſband at fourteen. However, if the female was under fourteen, when the lord's wardſhip commenced,

commenced, he might keep her under ward till ſixteen, by ſtat. Weſt. 1. 3 Edw. I. cap. 22. This wardſhip was taken from the lord by the charter of Henry I. and transferred to the widow or next of kin. But this noble immunity did not continue long. When the male heir arrived to the age of twenty-one, and the heir-female to that of ſixteen, they might ſue out their livery or *ouſter le main*, *i. e.* the delivery of their lands out of their guardian's hands; but for this they were obliged to pay a fine, *viz.* half a year's profit of the land.

Theſe guardians had alſo another kind of power over their infant wards, which was that of diſpoſing of them in matrimony: and if the infants refuſed a ſuitable match, they forfeited the value of the marriage to their guardian; but if they married without his conſent, they forfeited double the value. (Litt. § 110.) This right of ſelling the ward in marriage was expreſsly declared by the ſtatute of Merton, 20 Hen. III. cap. 6. Theſe grievances, and others of a ſimilar nature, were firſt aboliſhed by the lords and commons in parliament, in 1645; and this ordinance was confirmed by the protector and his parliament in 1656; and they were finally aboliſhed by the ſtatute 12 Car. II. cap. 24, and by 20 Geo. II. cap. 43. and cap. 50. The ſame are alſo aboliſhed in Scotland. (See KNIGHT'S *ſervice*.) Upon the abolition of the COURT *of wards*, the care which the crown was bound to take, as guardian of its infant tenants, was totally extinguiſhed in every feodal view; but reſulted to the king in his court of chancery, together with the general protection of all other infants in the kingdom. (F. N. B. 27.) When therefore a fatherleſs child has no other guardian, the court of chancery hath a right to appoint one; and from all proceedings relative to it, an appeal lies to the houſe of lords. The court of exchequer can only appoint a guardian *ad litem*, to manage the defence of the infant if a ſuit be commenced againſt him: a power which is incident to the juriſdiction of every court of juſtice (Cro. Jac. 641. 2 Lev. 163. T. Jones 90.); but when the intereſt of a minor comes before the court judicially, in the progreſs of a cauſe, or upon a bill for that purpoſe filed, either tribunal indiſcriminately will take care of the property of the infant.

GUARDIAN *in ſocage*. See GUARDIAN above, and SOCAGE.

GUARDIAN *of the ſpiritualities*, is the perſon to whom the ſpiritual juriſdiction of a dioceſe is committed, during the time of the vacancy of the ſee.

This guardian may be either ſuch in law, *i. e. jure magiſtratus*, as the archbiſhop is of any dioceſe within his province; or by delegation, as he whom the archbiſhop, or vicar-general, does for the time depute.

The dean and chapter of Canterbury are guardians both for the dioceſe and the whole province during a vacancy of the archbiſhopric; ever ſince the office of prior of Canterbury was aboliſhed at the reformation. 2 Roll. Abr. 22.

GUARDIAN *of the Church*. See CHURCH-*warden*.

GUARDIAN, or *Warden*, of the Cinqueports, is an officer who has the juriſdiction of the Cinqueports, with all the power that the admiral of England has in other places.

Camden relates, that the Romans, after they had ſettled themſelves and their empire in our iſland, appointed a magiſtrate, or governor, over the eaſt parts, where the Cinqueports lie, with the title of *comes litoris Saxonici per Britanniam*; having another, who bore the like title, on the oppoſite ſide of the ſea. Their buſineſs was to ſtrengthen the ſea-coaſt with munition againſt the outrages and robberies of the barbarians. And that antiquary takes our warden of the Cinqueports to have been erected in imitation hereof. See CINQUEPORTS.

GUARDIAN *of the Peace*. See CONSERVATOR *of the peace*.

GUARDIANI, in *Geography*, a ſmall iſland in the Grecian Archipelago, near the S. coaſt of Cephalonia.

GUARDO, or GOVARDO, a town of Italy, in the department of the Mela, on the Chieſa; 10 miles N.E. of Breſcia. N. lat. 45° 38'. E. long. 10° 26'.

GUARDUCCI, TOMMASO, in *Biography*, a native af Florence, and ſcholar of Bernacchi, arrived in England in the autumn of 1767, at the beginning of the opera regency of Meſſrs. Gordon and Vincent. He was tall and aukward in figure, inanimate as an actor, and in countenance ill-favoured and morbid; yet, with all theſe diſadvantages, he was one of the moſt correct ſingers we ever heard; and a man of great probity and worth in his private character. He was unfortunate in arriving here ſoon after Manzoli, the impreſſions of whoſe great voice and majeſtic manner of ſinging had not been effaced by his immediate ſucceſſor, Eliſi. Guarducci's voice, though of much leſs volume than Manzoli's, was clear, ſweet, and flexible. His ſhake and intonations were perfect, and by long ſtudy and practice he had vanquiſhed all the difficulties of his art, and poſſeſſed himſelf of every refinement of his particular ſchool, as well as of the general vocal embelliſhments of Italy at this period.

Though prejudice ran high againſt him on his firſt arrival in London, his merit at length made its way, and his highly poliſhed manner of ſinging was very much approved and felt by the principal profeſſors and perſons of taſte and diſcernment who heard him. He ſoon diſcovered that a ſinger could not captivate the Engliſh by tricks or inſtrumental execution, and told the author of this article, ſome years after, at Montefiaſcone in Italy, that the gravity of our taſte had been of great uſe to him. "The Engliſh (ſaid he) are ſuch friends to the compoſer and to ſimplicity, that they like to hear a melody in its primitive ſtate, undiſguiſed by change or embelliſhment. Or if, when repeated, *riſſioramenti* are neceſſary, the notes muſt be few and well ſelected, to be honoured with approbation."

Indeed, Guarducci was the plaineſt and moſt ſimple ſinger, of the firſt claſs, whom we ever heard. All his effects were produced by expreſſion and high finiſhing, nor did he ever aim at execution. He ſung in the Engliſh oratorios upon ſhort notice, with very little knowledge of our language, and ſtill leſs practice in pronouncing it. However, he was well received and well paid, for he had 600*l.* for twelve oratorios, a larger ſum than was ever given on a like occaſion, till the time of Miſs Linley.

In October, the King's theatre was opened, with a new ſerious opera, by different authors, entitled "Tigrane," in which the admirable cantabile air, "Care luci," compoſed by Sacchini, was ſung in an exquiſite manner by Guarducci. This air, the firſt that was ever performed on our ſtage of Sacchini's compoſition, was printed without his name.

In December, another paſticcio opera, called "Sifare," was performed, in which Guarducci gained great applauſe by his poliſhed manner of ſinging a ſimple and elegant air by Galuppi, "Quel labro addorato," which was conſtantly encored during the run of the opera. Abel compoſed an air for him in this drama, "Frena le belle legrime," with an accompaniment for the *viol da gamba*, which he played himſelf; but it was laboured, and had not the effect that might be expected from the united powers of two ſuch complete muſicians.

Guarducci, inſtead of an opera, had for his benefit, in the ſpring of 1764, the oratorio of "Betulia liberata," writ-

ten by Metaſtaſio, and ſet by Jomelli, in which, among many other admirable compoſitions, Guarducci had an air of ſupplication, through which were heard the cries of the people for peace and bread, in a diſtant chorus, ſung extremely ſoft; this was juſtly admired for its new and fine effect.

Soon after he had quitted this country, when we called upon him in 1770, at Monteſiaſcone in the way to Rome, he had built himſelf a very good houſe, fitted it up in the Engliſh manner, with good taſte. He had previouſly purchaſed a winter houſe in Florence, and built this at Monteſiaſcone, the place of his birth, to retire to in ſummer, and to receive his mother, and his brothers and ſiſters; it is charmingly ſituated, commanding, on one ſide, a fine proſpect of the country, as far as Aquapendente, and a great part of the lake Bolſena; and on the other, the hills of Viterbo, and the country leading to it.

He ſaid, that he had totally quitted the ſtage, and intended ſinging no more in public; this would have been a loſs to his country; as we found that he was then allowed by the Italians the firſt place among all the ſingers of that period; and at Rome, they continued to ſpeak of his performance in Piccini's "Didone Abbandonata" with rapture.

But alas! this ſingularly regular, prudent, and worthy man, after he had retreated from the ſtage, and imagined himſelf ſafely landed, and out of the reach of public caprice, and frowns of fortune, was obliged, ten years after, when his youth was gone, and his powers of pleaſing rapidly on the decline, again to mount the ſtage for a ſubſiſtence, by having been perſuaded by his friends to truſt his whole property, for the ſake of high intereſt, to a merchant at Leghorn, who, becoming a bankrupt, left him without a ducat to carry on his eſtabliſhment for his family or his own ſupport! We relate this melancholy ſtory as another beacon to future great theatrical performers, who by toil, labour, and economy, have acquired and accumulated a proviſion for age, change of faſhion, and infirmities, not to be tempted to truſt their property without ſafe and ſolid ſecurity to merchants; the riſk being always proportioned to the promiſed premium, which, when inordinate, even men intentionally honeſt are unable to pay.

GUAREA, in *Botany*, a barbarous word, from *Guara*, the name given to this tree by the inhabitants of Cuba.—Allamand in Linn. Mant. 150. Schreb. 254. Willd. Sp. Pl. v. 2. 332. Cavan. Diſſ. 366. Mart. Mill. Dict. v. 2. Juſſ. 265. Lamarck. Illuſtr. t. 301.—Claſs and order, *Octandria Monogynia*. Nat. Ord. *Tribilatæ*, Linn. *Meliæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in four deep, ſhort, flattiſh, obtuſe, equal ſegments. *Cor.* Petals four, erect, linear, acute. Nectary tubular, ſomewhat cylindrical, entire, the length of the corolla. *Stam.* Filaments none; anthers eight, attached to the inner margin of the nectary. *Piſt.* Germen globoſe, ſtanding on a cylindrical receptacle, crowned with a glandular border; ſtyle thread-ſhaped, prominent; ſtigma capitate, depreſſed, undivided. *Peric.* Capſule globoſe, umbilicated, with four furrows from the centre, of four cells, and four thick hard valves. *Seeds* ſolitary, oblong, clothed with a ſcarlet arillus.

Eſſ. Ch. Calyx four-cleft. Petals four. Nectary cylindrical, bearing the anthers on its edge. Capſule with four cells and four valves. Seeds ſolitary, with an arillus.

Obſ. Very near *Trichilia*, from which it was ſeparated by Linnæus, at the ſuggeſtion of F. Allemand, a ſurgeon who travelled in South America and the Weſt Indies, and ſent him many deſcriptions, with ſome ſpecimens, of plants. This gentleman was nephew to the late profeſſor Allemand of Leyden. See ALLAMANDA.

1. *G. trichilioides*. Linn. Mant. 228. Cavan. Diſſ. 366. t. 210. Swartz. Obſ 146. (Trichilia Guara; Linn. Sp. Pl. 551, excluding Browne's ſynonym. Melia Guara; Jacq. Amer. 126. t. 176. f. 37. Eleutheria arborea; Browne Jam. 369. Lauro affinis arbor, &c. Alleygator or Muſk-wood; Sloane Jam. v. 2. 24. t. 170. f. 1. Guidonia nucis juglandis foliis major; Plum. Ic. 139, excluding the ſynonyms, t. 147. f. 2. Jito; Pis. Bras. 79. t. 70.)

This, the only known ſpecies, is a tree of moderate ſize, growing in Brazil, Jamaica, and other parts of the Weſt Indies. The bark and wood, as well as all parts of the plant, are ſaid to ſmell ſtrongly of muſk, and the wood abounds with a bitter reſin, which, as well as its muſky flavour, renders it totally unfit for making rum caſks. The *leaves* are large and handſome, abruptly pinnate, compoſed of three or four pair of elliptical, pointed, entire, ſmooth leaflets. *Flowers* whitiſh, in axillary branched cluſters, often a foot long. *Capſule* nearly globular, bigger than a hazel nut.

Piſo ſays the bark of the root is an active and dangerous purge, and Browne, that the powder of the bark in general is uſed by the negroes of Jamaica as an emetic.

GUARGA, in *Geography*, a river of Africa, in the kingdom of Fez, which runs into the Seba; 30 miles E.N.E. of Mahmora.

GUARIBA, in *Zoology*. See SIMIA *Beelzebul*.

GUARICO, otherwiſe called *Cape* FRANCOIS, in *Geography*, a town that lies on the N. W. ſide of the iſland of St. Domingo, in N. lat. 19° 45' 48", and 73° 0' 45" W. of the meridian of Paris, according to the obſervation of Don George Juan, taken on the ſpot. The town is about one-third of a league in length, and contains between 13 and 15 hundred inhabitants, who are a mixture of Europeans, white creoles, negroes, mulattoes and caſts; the latter being the moſt numerous. Since a dreadful fire, which deſtroyed the town, the houſes, which were conſtructed of wood, are now built of ſtone, and in general they have only a ground floor. The town contains, beſides a pariſh church, a college of Jeſuits, a nunnery of Urſulines, a convent, and a ſpacious hoſpital. The adjacent country is well cultivated, and laid out in plantations of ſugar, indigo, tobacco, and coffee. The trade carried on from this port was formerly very great, as no leſs than 160 veſſels, from 150 to 4 or 500 tons, annually reſorted to it from France. The climate is extremely hot, and ſubjects the inhabitants to malignant fevers and dyſenteries. The harbour, though open to the E. and N. is very ſecure, being incloſed by a ridge of rocks, which fence it againſt the impetuoſity of the ſea.

GUARIN, PETER, in *Biography*, was born at Rouen in the year 1678. When he was about eighteen years of age he joined the order of Benedictine monks, and ſoon became ſuch a proficient in the Greek and Hebrew languages, that he was appointed profeſſor of them. He was author of "A Hebrew Grammar," in two vols. 4to. and employed much of his time and labour on the compoſition of "A Hebrew Lexicon," which was publiſhed, after his death, in two vols. 4to. It was entitled "Lexicon Hebraicum et Chaldæo-biblicum," &c. Guarin completed that part of it only which reaches to the end of the letter *mem*: the remainder was executed by Le Tournois and others belonging to the congregation of St. Maur.

GUARIN, in *Geography*, a town of Peru, in the dioceſe of La Paz; 60 miles N. N. W. of La Paz.

GUARINI, BATISTA, in *Biography*, was born at Ferrara in 1587. He was educated at Piſa, Padua, and in his native city, in the univerſity of which he was for ſome years the profeſſor of belles lettres. At the age of thirty he entered into

the ſervice of Alfonſo II. duke of Ferrara, who created him a cavalier, and employed him in various embaſſies. In reward for his ſervices the duke nominated him his ſecretary; but, through ſome diſguſt, he reſigned his employment in leſs than two years. The anger of his maſter obliged him to quit the courts of Mantua and Savoy, to which he had ſucceſſively reſorted. After many years he returned to Ferrara, whence he was delegated, in 1605, to compliment pope Paul V. on his acceſſion. He died at Venice in 1612. He was author of various works, conſiſting of Latin orations; letters; poems, &c. alſo of "Il Secretario," or the art of letter writing; a comedy entitled "Idropico." His fame as a poet reſts entirely upon his famous dramatic paſtoral, the "Paſtor Fido." It has gone through a multitude of editions, and is regarded as one of the ſtandard productions of Italian poetry, which place it deſerves on account of the variety and intereſt of its action, and the warmth and beauty of its language.

GUARINO, ſurnamed *Veroneſe*, was born at Verona about the year 1370. He was the pupil of John of Ravenna; but not ſatisfied with the degree of knowledge which he obtained under him, he ſailed to Conſtantinople about his twentieth year, in order to learn Greek of Manuel Chryſoloras. On his return to Italy he began to keep an open ſchool, and he paſſed, ſucceſſively, to Florence, Bologna, Padua, Trent, Verona, Venice, and Ferrara. He had many ſcholars, who ſhewed themſelves worthy of their maſter, to whom is, in great part, owing the reſtoration of ancient elegance in the Greek and Latin languages, which took place in the 15th century. At Ferrara he was invited to undertake the education of Leonello d'Eſte, ſon of the marquis, Nicholas III. in 1429, and here he was appointed to the profeſſorſhip of the learned languages. He founded a family in that city, where he died in 1460, at the age of 90. He was engaged, as a writer, in the uſeful taſk of tranſlating the ancient Greek authors into Latin. He gave verſions of many lives of Plutarch, and of other pieces by that author. At the command of pope Nicholas V. he tranſlated the firſt ten books of Strabo's Geography, which were printed, with the verſion of the other ſeven, by Gregory Tiferno: theſe were afterwards tranſlated by Guarino. He was author, likewiſe, of ſome grammatical treatiſes on the Greek and Latin languages; of commentaries upon ancient authors; of orations on various occaſions; and of ſome Latin poems.

GUARINO, BATISTA, a ſon of the preceding, was born at Verona. He opened a ſchool for the learned languages at Ferrara in 1461, and became one of the moſt celebrated profeſſors of his time. He had among others, for his ſcholars, Giraldi and Aldo Manuzio, of whom the latter dedicated to him his edition of Theocritus in 1495. He was ſelected by Borſo, duke of Ferrara, as ambaſſador for the court of France; and he was honoured with the title of ſenator by the king of Naples. As an author, he is known by his poems in four books, which were printed at Modena in 1496; and by letters and orations on various ſubjects. He wrote comments upon Lucan, Catullus, and Cicero's epiſtles, and tranſlated ſome of the orations of Demoſthenes, Dio Chryſoſtom, and St. Gregory Nazianzen.

GUARINONE, CHRISTOPHER, a native of Verona, who acquired conſiderable reputation, as a phyſician, about the end of the 16th century. He graduated at Padua; and, on his return to Verona, taught philoſophy privately, and at the ſame time practiſed his profeſſion with ſo much diſtinction, as to be appointed firſt phyſician to the duke of Urbino, and afterwards to be invited to the court of Prague, by the emperor Rodolf II. Guarinone eſtabliſhed a medical academy or ſociety, which met weekly in his own houſe. He died at Prague, in 1602, at a very advanced age. He was author of the following publications:—1. "Commentaria in primum Librum Ariſtotelis de Hiſtoria Animalium." Francfort, 1601.—2. "Tractatus de Methodo doctrinarum;" ibid. 1601.—3. "De generatione viventium, etiam naſcentium ex putredine;" ibid. 1601.—4. "De principio venarum;" ibid. 1601.—5. "De natura humana ſermones quatuor," 1601.—6. "Conſilia Medicinalia, in quibus univerſa praxis medica exactè pertractatur," Venet. 1610. Eloy. Dict.

GUAROMINI, in *Geography*, a bay on the coaſt of Brazil. S. lat. 23° 30'.

GUAROUBA, in *Ornithology*, a ſpecies of *Pſittacus*; which ſee.

GUARUGUARU, in *Ichthyology*, the name of a ſmall American freſh-water fiſh, ſeldom exceeding an inch and half in length, and of a very ſlender body. It is eaten, though very ſmall, being very well taſted. It is caught in abundance in lakes and ponds.

GUASABAS, in *Geography*, a town of New Navarre; 220 miles S. S. E. of Caſa Grande.

GUASAI, or KUA-SAY, a town of Tonquin, on a river which runs into the Chineſe ſea. N. lat. 17° 36'. E. long. 105° 40'.

GUASAIBON, a town of the iſland of Cuba; 25 miles W. of Havanna.

GUASCO, a town of Chili, at the mouth of the river Guaſco, which runs into the Pacific ocean. S. lat. 27° 20'.

GUASTALLA, a town of Italy, in the department of the Mincio, near the Po, at the union of the rivers Croſtollo and Tagliata, with a ſmall territory, to which is annexed the title of duchy, ceded by the treaty of Aix-la-Chapelle, in 1748, to the duke of Parma. In 1806, the principality was given to the prince of Borgheſe, who married the princeſs Paulina; 21 miles N. W. of Parma. N. lat. 44° 56'. E. long. 10° 39'.

GUASTECA of *D'Anville*, or PANUCO, a province of the domain of Mexico, bounded on the N. by the new kingdom of Leon, on which quarter it is rather barren; and on the S. bordering on Mexico proper, where it is not only fertile, but has mines of gold and one real of ſilver, dependent on Zucatecas, whence it is diſtant three leagues. In Arrowſmith's map, and in that of Alzate, this province is ſupplanted by that of Santander; Panuco, the capital, being placed in the province of Mexico. This, however, is a very ſmall diſtrict.

GUATIMALA, one of the ſeven grand territories or domains, often called kingdoms by the Spaniſh authors, into which the dominions of Spain in North America are diſtributed. This territory contains the following provinces, *viz.* Veragua, Coſta Rica, Nicaragua, Honduras, Xeſes, or Choletuca, Tiguelgalpa, St. Miguel, St. Salvador, Sonſonate, Suchitepec, Soconuſco, (of which the ſeven diſtricts laſt enumerated form what is called Guatimala in the maps,) Icalcos, Vera-Paz, Chiapa, and Yucatan. The large domain of Guatimala is ruled by a preſident, who is alſo captain-general, or commander of the troops, but ſubordinate to the viceroy of Mexico. This is one of the three royal audiences, and it contains 25 bailiwicks. The royal audience, or high court of juſtice, was eſtabliſhed in 1544. The ſoil of this province is fertile, and the country abounds in corn, cattle, cochineal, honey, wax, ſugar, cotton, and indigo; it is mountainous, with numerous volcanos, and ſubject to earthquakes. See the deſcription of each province reſpectively.

GUATIMALA, the capital of the above-mentioned domain, the ſeat of a royal audience, and the ſee of an archbiſhop, eſtabliſhed

eſtabliſhed in 1742, was founded by the name of St. Jago, at the ſide of a volcano, in a valley about three miles wide, opening gradually towards the South ſea, between two mountains, and containing 7000 families. It was deſtroyed by an earthquake in 1751, and, after being rebuilt, was again deſtroyed by the ſame calamity in 1775; but it was again rebuilt at the diſtance of about 25 geographical miles farther to the ſouth, on the river Vaccas, near the Barra de Iſtapa of D'Anville, now called the harbour of Guatimala. It has churches and convents, though their number is not preciſely ſpecified, and an univerſity, which begins to adopt uſeful plans of education. The inhabitants are celebrated for perſonal beauty and ſweetneſs of diſpoſition; the women being reputed the handſomeſt in Spaniſh America, which ſome have aſcribed to the moiſture of the climate. The number of inhabitants has not been aſcertained, nor even mentioned by any writer, but is probably equal, if not ſuperior, to that of Guadalaxara. N. lat. 14° 28'. W. long. 92° 40'.

GUATIMAPE, a town of Mexico, in New Biſcay; 105 miles N.N.W. of Durango.

GUATIMAR, a town of the iſland of Cuba; 50 miles N.N.E. of St. Jago.

GUATIMOZIN, in *Biography*, laſt king of Mexico, was nephew of Montezuma, and ſucceeded to the throne on the death of Quetlevaca, in 1520. He was raiſed to this high diſtinction ſolely by his talents and proweſs, which pointed him out as a proper perſon to defend the rights of his country againſt the Spaniards. A new invaſion of Mexico by thoſe mercileſs plunderers ſoon called forth his energies into action. He ſhewed himſelf worthy the choice of his friends, exerted all his powers in the defence of his capital, and repulſed an attempt by Cortes to take it by ſtorm. In the progreſs of the ſiege he preſerved an unſubdued ſpirit, and rejected all the propoſals of the enemy, though they were almoſt daily gaining ground. At length he was perſuaded to attempt a retreat acroſs the lake, but was intercepted and made priſoner. Finding reſiſtance in vain, he ſurrendered with a dignified compoſure, requeſting only that no inſult might be offered to the empreſs and his children. When brought into the preſence of Cortes, he appeared with neither the fierceneſs of a barbarian, nor the dejection of a ſupplicant. "I have done," ſaid he, "what became a monarch. I have defended my people to the laſt extremity. Nothing now remains but to die. Take this dagger," laying his hand on one which Cortes wore, "plant it in my breaſt, and thus put an end to a life which can no longer be of uſe." The Spaniſh commander, whoſe name muſt be for ever tranſmitted to poſterity with the infamy which it deſerves, irritated by the ſmallneſs of the treaſures found in the captured city, ordered the hero to be put to the torture, in order to force a diſcovery of more. The unfortunate prince, together with his chief, was ſtretched on burning coals. Guatimozin endured the torments with the utmoſt patience and reſignation, but his fellow-ſufferer, overcome by the violence of the anguiſh, turned a dejected eye to his maſter, which ſeemed to implore his permiſſion to reveal the ſecret. But the high ſpirited prince, darting on him a look of authority mingled with ſcorn, checked his weakneſs by aſking, "Am I now repoſing on a bed of roſes?" Overawed by the reproach, he perſevered in dutiful ſilence, and ſhortly after expired. Cortes, the ſavage Cortes, aſhamed of the horrid ſcene, reſcued the royal victim from the hands of his torturers, and prolonged a life reſerved for new indignities and ſufferings; and upon an inſurrection of the Mexicans, in which he could have had no ſhare, the Spaniſh commander cauſed him to be hanged without even a hearing. This foul deed was perpetrated in 1522.

GUATO, in *Geography*, an iſland in the S. Pacific ocean, near the coaſt of Chili; 20 miles long and five broad. S. lat. 44° 40'.

GUATUCUPA, in *Ichthyology*. See LABRUS *Cromis*.

GUAVA, in *Botany*. See GUAIAVA.

GUAURA, in *Geography*, a town of Peru, in the audience of Lima; 70 miles N.N.W. of Lima. S. lat. 11°. W. long. 7° 26'.

GUAXACA, now called *Oaxaca*, the capital of a province of the ſame name in the domain of Mexico. It is much celebrated for its abundant harveſts of cochineal. It is ſituated at the opening of three large plains, one of which extends to the town of Guatimala, at a great diſtance. It is watered by a beautiful river, and is amply ſupplied with pure waters from the mountains on the N. E. by ſeveral aqueducts. The air is clear and healthy, being refreſhed in the morning by the eaſt wind, and by the weſt in the evening; and the climate preſents perpetual ſprings. Thiery, who viſited this city in 1777, adds in his deſcription of it, that it is diſtinguiſhed by magnificence of ſituation, artificial beauty, excellence of ſoil, temperature of climate, and abundance of fruits of Europe and America in conſtant ſucceſſion. Nothing is wanting, he ſays, to render Oaxaca an enchanting city but ſuperior induſtry. Its numerous ſpires and houſes give it a majeſtic appearance. The form is an oblong ſquare, about two miles by $1\frac{1}{2}$, including the ſuburbs, which are full of gardens, and of plantations of nopal, a kind of cactus, which feeds the cochineal inſect. The ſtreets are wide and ſtraight, and well paved; and the houſes, of two floors, are built of ſtone. The town-houſe in the great ſquare, recently erected, is built with ſtone of a ſea-green colour. The biſhop's houſe and the cathedral form two other ſides of the ſame ſquare, ſurrounded with arcades, as a fence from the rain and ſun. The other churches and monaſteries, which are numerous, are ſolidly built and richly decorated. Here are a biſhop and provincial governor, ſubordinate to the governor of Guatimala, to which audience the province belongs. The population, compriſing Indians, mulattoes, and negroes, amounts to about 24,000 perſons. The province of Oaxaca is eſteemed the moſt fertile of the whole kingdom of Guatimala; and, beſides cochineal, produces abundance of excellent chocolate. It has manufactures of black wax; and the kernels of a fruit are ingeniouſly painted with miniatures. Eſtella reckons among the productions of this province, ſugar, cotton, rice, chocolate, plantains, cochineal, and caſſia. It has alſo mines of gold, ſilver, lead, and cryſtal; and moſt of the rivers roll particles of gold. The inhabitants, however, want induſtry. In this province there are only two manufactures of indigo, and 507 looms employed in weaving cotton. This celebrated city is ſubject to earthquakes, and was a conſiderable ſufferer from the laſt that happened in New Spain. N. lat. 17 30'. W. long. 108° 36.

GUAXACATLAN, a town of Mexico in the province of Guadalaxara; 60 miles N. W. of Guadalaxara.

GUAYAQUA, a town of S. America, in the government of Tucuman; 125 miles N. of St. Salvador de Jugui.

GUAYAQUIL, a celebrated commercial province of New Granada, near the Pacific ocean. This province, during the winter months, from December to May or June, is much incommoded by the elements, inſects, and vermin. It is ſubject to an extraordinary inundation, reaching as far as the Andes, whither the inhabitants then retire with their herds. The inceſſant rains are alſo accompanied with frequent and dreadful

dreadful tempeſts of lightning and thunder. During the rainy ſeaſon Reaumur's thermometer is generally between 24° and 28°. In this ſeaſon fevers, diarrhœas, dyſenteries, vomiting, and ſpaſms, are diſeaſes that prevail, and are frequently fatal. The "boba," or ſerpent, of prodigious ſize, is found here, and there is alſo a ſerpent about a palm in length, and of a bright ſilver colour, whoſe bite is mortal in 24 hours. Innumerable ſwarms of inſects and vermin infeſt both the air and ground. The ſnakes, poiſonous vipers, ſcorpions, and ſcolopendræ, find their way into the houſes to the great moleſtation and even deſtruction of many of the inhabitants. Some of theſe animals have found their way into the beds: and the inhabitants, in order to ſecure themſelves from danger, are under a neceſſity of carefully examining their houſes and their beds, and for preventing the acceſs of the moſquitoes and other inſects, all perſons, even the negro ſlaves and Indians, have canopies over their beds. In ſummer the number and activity of theſe vermin are diminiſhed. During the inundation the caymans, ſome of which are of the enormous length of nine yards, ſpread over the country; but in the dry ſeaſon, from June to December, they are leſs troubleſome. This ſeaſon, which, within the tropics, is the coldeſt, in ſome degree invigorates the inhabitants, who are enervated and rendered indolent and liſtleſs by the climate. At Babahoyo there is an annual fair, where the people of Guayaquil meet thoſe of Quito and the adjacent towns. But in the rainy ſeaſon Babahoyo is inacceſſible, the inundation forming an oval lake about 20 miles in length, while the villages on the heights can be approached by boats. The churches, on account of the inundation, are always on the ſummits: when the overflowing waters have ſubſided, the beauty of the meadows and woods ſurpaſſes all deſcription. The products of this juriſdiction are tobacco, not much eſteemed, wax, cotton, and principally large trees, fit for building and repairing ſhips.

The juriſdiction of Guayaquil begins at Cape Paſſado, ſo called from its lying 21′ S. of the equinoctial, and about half a degree N. of the bay of Manta. From this cape it continues along the coaſt, including the iſle of Puna, to the town of Machala, on the coaſt of Tumbez, where it is terminated by the juriſdiction of Piura. From thence it runs away eaſtward, and is bounded by that of Cuença; and then turning northward along the weſtern ſkirts of the Andes, it terminates on thoſe of Bamba and Chimbo. Its length from N. to S. is about 60 leagues, and its breadth from E. to W. 40 or 45, reckoning from the point of Santa Elena to the parts called Ojibar. The whole country, like that in the neighbourhood of the city, is a continued plain, and in winter univerſally overflowed. It is divided into ſeven lieutenancies or departments, for each of which the corregidor appoints a lieutenant or deputy, who is confirmed by the audience of Quito. Theſe departments are Puerto Viejo, Punta de Santa Elena, Puna, Yaguache, Babahoyo, Baba, and Daule. The firſt has a capital of the ſame name, and includes the towns of Monte Chriſto, Picoaſa, Charapoto, and Xipijapa. The ſecond comprehends the towns of Punta, Chongon, Morro, Colonche, and Chandui. The third department, or that of Puna, is an iſland at the mouth of the Guayaquil river, extending N.E. and S.W., between ſix and ſeven leagues, and is of a quadrilateral figure. Formerly it is ſaid to have contained between 12 and 14 thouſand inhabitants; but it has now only one ſmall town, ſituated at the head of its harbour in the N.E. part. To this lieutenancy has been annexed the town of Machala, on the coaſt of Tumbez, together with that of Naranjal, the landing place of a river of the ſame name, called alſo the Suya. The juriſdictions of Machala and Manaranjol produce great quantities of cacao, and that of the former is eſteemed the beſt in the whole province of Guayaquil. The lieutenancy of Yaguache is at the mouth of a river of the ſame name, which falls into the Guayaquil on the S. ſide, and riſes from the ſkirts of the Cordilleras, S. of the river Bamba. Its juriſdiction contains three towns. Its chief product is wood and a little cacao: but cattle and cotton are the principal objects of attention to its inhabitants. For an account of Babahoyo and Baba, ſee theſe articles. The lieutenancy of Daule includes a town of the ſame name, and is waſhed by a river, to which it owes its appellation. It contains many ſpacious houſes belonging to the inhabitants of Guayaquil. Here are numerous plantations of tobacco of excellent quality, ſugar-canes, cacao, and cotton; together with large orchards of fruit-trees and extenſive corn fields. The river Daule diſcharges itſelf into the Guayaquil: it is very large, and on both a great trade is carried on with that city. The buſineſs of grazing is followed in all theſe lieutenancies, more or leſs; in proportion to their extent, the nature of the ſoil, and the convenience of driving the cattle to the mountains, beyond the reach of the inundations. Juan and Ulloa's Voyage to South America, vol. i.

GUAYAQUIL, a city, the capital of the above province, ſituated in the ſouthern part of the vice-royalty of Granada, on a river near the Pacific ocean. It was founded about the year 1534 or 1535; but after being deſtroyed by the Indians, it was re-built in 1537, at ſome diſtance from its firſt ſituation, on the declivity of a mountain: and in 1693, conſiderable additions were made to it, at the diſtance of five or ſix hundred toiſes, communicating with the old part by a long bridge. The city extends along the bank of the river from the lower part of the old town to the upper part of the new, near half a league, but the breadth is not proportional to the length. The houſes of both towns are chiefly conſtructed of wood; but ſince the year 1767, they have begun to uſe whitened earth, as being leſs ſubject to accidents from fire. After the almoſt general conflagration in 1764, it was prohibited by the audience of Quito, and by the ſuperior government of Santa Fé, to thatch the houſes with ſtraw, or to encompaſs them with boards or canes. The city had been before nearly ruined by 11 different conflagrations; but by reaſon of its advantageous ſituation for commerce, it has always reſumed its primary ſtation. The ſtreets of the new town are ſtraight, and ſufficiently wide, but having no declivity, the rain-water ſtagnates and occaſions diſorders; and the filth is increaſed by theſe pools being made the receptacles of ordures. Guayaquil is now become one of the handſomeſt towns of Spaniſh America; the ſtreets having been paved, and an arcade running before all the houſes, ſo that walkers are protected from the ſun and rain. The houſes are alſo improved, and covered with tiles. Nevertheleſs, the marſhes in its vicinity, which infect it with peſtilential vapours, and the water, tainted with ſtreams from theſe marſhes, and from the filth of the town, render it inſalubrious and ſubject to diſeaſe. The city has a parochial church, two convents, a college of Jeſuits, and an hoſpital. Both the city and its juriſdiction are under a corregidor, nominated by the king, and he holds his office five years; for the police and civil government Guayaquil has ordinary alcaldes, and regidores. The revenue is managed by a treaſurer and an accomptant, who receive the tributes of the Indians, the duties on imports and exports, and the taxes on commodities, which are either conſumed in the city, or carried through it. The eccleſiaſtical government is lodged in the biſhop of Quito's vicar, who is generally alſo the prieſt of the town. The city is defended

by three forts, two on the river near the city, and the third behind it, guarding the entrance of a ravine. The number of inhabitants may now be eſtimated at about 10,000; though it is ſaid to have been formerly much more conſiderable, owing to the influx and temporary abode of ſtrangers, drawn thither by commerce. Many of its eminent families are Europeans, who have married there; beſides theſe, and ſubſtantial creoles, the other inhabitants are of different caſts, as in other cities of this part of America. In ſpite of all the local diſadvantages of this town, with reſpect to ſalubrity, it is ſuppoſed to be now increaſing, the trade offering many benefits to ſettlers, who are often fixed in marriage by the charms of the women; for an ugly woman in Guayaquil is mentioned as a proverbial rarity. The freedom of commerce, eſtabliſhed in 1778, has improved the advantages of this city, ſo conveniently ſituated for trade with both North and South America. In 1794, there was built on the little iſle of Puna, near the mouth of the Guayaquil river, at the royal expence, a wooden fortreſs, with a battery to defend the harbour. This is the reſidence of the officers who viſit the ſhips that enter and depart. On the ſouth of the iſland are ſalt-works. Many Spaniſh ſhips which uſed to ſtop in the bay of Callao, proceed directly to Guayaquil; and the balance of the trade with Lima is in its favour. Guayaquil is indeed now in ſuch a ſtate of progreſſive improvement, that thoſe who knew it formerly would ſuppoſe it quite another city. Poſſeſſed of almoſt the only grand and genuine haven on the weſtern coaſt of South America, this city may well avail itſelf of its advantages. Acceſſible by a broad and majeſtic river, leading to the port of Puna, at the diſtance of eight leagues, though large ſhips might proceed, it is uſual to transfer the cargoes to balzas, a kind of navigable rafts, formed of large beams, of a wood nearly as light as cork. Upon theſe rafts the maſters ſometimes even form their habitations, adorned with little beautiful gardens, ſo that when the ſhips arrive, the whole river preſents, as it were, a floating city. (See Boat.) One great advantage belonging to Guayaquil is, that its ſituation renders it a proper arſenal for the conſtruction of ſhips; having abundance of ſuitable timber in its vicinity, and proviſions being very cheap. It was accordingly named for that purpoſe in a royal ordinance of 1767. The timber is not only abundant and excellent, but may be eaſily conveyed thither by numerous rivers. The balſam tree, the cinnamon tree, the pechiche, the guachapeli, whoſe roots yield ſtrong curves; all theſe, and many others, are celebrated for their duration, and for their reſiſtance to worms, and other accidents of the ſea. The government of Guayaquil is chiefly military, there being two companies of infantry, who form the garriſon alternately, with two others at Quito. S lat. 2 12'. W. long. 79 6'.

Guayaquil, a river of South America, which riſes in the Cordilleras, and purſues a ſerpentine courſe, ſubject to great ſwellings from the torrents that are precipitated from theſe mountains, to Iſla Verde, in the bay of Puna. The diſtance of the navigable part of this river from the city of Guayaquil to the cuſtom-houſe at Babahoyo, where the goods are landed, is 24½ leagues; and to Caracol, the landing place in winter, 28½ leagues. The diſtance from Guayaquil to Iſla Verde is computed at about ſix leagues, and from Iſla Verde to Puna three leagues: ſo that the whole diſtance from Caracol, the moſt inland part up the river, to that of Puna, is 37½ leagues. The mouth of the river at Iſla Verde is about a league in breadth, and ſomewhat broader at Guayaquil, above which it contracts itſelf as it advances nearer the mountains, and forms various creeks. In ſummer the tides reach as far as the cuſtom-houſe; but in winter the current is ſo ſtrong and rapid, that three or four times in the year the tides are imperceptible. The floods, to which this river is ſubject, ſhift the banks of ſand that lie between the city and Iſla Verde, ſo that no ſhips of any conſiderable burden can go up with ſafety, unleſs great caution and frequent ſoundings are practiſed. The borders of this river, like thoſe of Yaguache, Baba, and Daule, as well as thoſe of the creeks and canals, are decorated with country ſeats, and cottages of poor people, of all caſts, for the convenience both of fiſhing and agriculture. The port of Guayaquil, at the mouth of this river, is the place where the goods from the provinces of Peru, Terra Firma, and Guatimala, conſigned to the cuſtoms, are landed; and, on the other hand, thoſe from the mountains, deſigned for the above mentioned provinces, are brought hither and ſhipped for their reſpective ports. The products of this country that are exported, are cacao and timber, cotton, rice, and fiſh, both ſalted and dried: horned cattle, mules, and colts; tobacco, guinea pepper, drugs, and ceibo wool, produced by a high and tufted tree of that name. The goods imported are wine, brandy, oil, and dried fruits from Peru; bays, flour, papas, bacon, hams, cheeſe, and other goods of the ſame kind from Quito; and from Panama, European goods purchaſed at the fairs. From New Spain it receives naphtha, tar, and cordage for the uſe of ſhipping. The tranſitory commerce conſiſts of the reciprocal exchange between the large kingdoms of Quito and Lima: the latter ſends the products of its vineyards and oliveyards, and the former furniſhes cloth, bays, ſerges, hats, ſtockings, and other woollen goods. Indigo is imported from New Spain by the merchants of Guayaquil, and ſent to the manufacturers of Quito.

GUAYAVAL, an iſland in the S. Pacific ocean, near the coaſt of Mexico. N. lat. 24° 20'.

GUAYCAMO, a town of S. America, in the province of Tucuman; 25 miles S.E. from St. Fernando.

GUAYCHA, a town of Peru, in the dioceſe of La Paz, on lake Titicaca; 80 miles N.N.W. of La Paz.

GUAYLAS, a juriſdiction of S. America, in the archbiſhopric of Lima, beginning 50 leagues from Lima, and extending N.N.E. along the centre of the Cordilleras. This juriſdiction is large, and has different temperatures of air. The low parts produce grain and fruits, the upper abound in cattle and ſheep, which form the greateſt branch of their trade.

GUAYMARAL, a town of S. America, in the province of St. Martha, on the Magdalena; 22 miles S. of Teneriffe.

GUAYNAMOTA, a town of Mexico, in the province of Guadaxara; 70 miles N.W. of Guadalaxara.

GUAYNI, a river of Guinea, which runs into the Atlantic. N. lat. 7 50'. W. long. 59 40'.

GUAYRA, La, a ſea-port town of S. America, in the government of the Caraccas, and the harbour of Leon de Caraccas. This town is placed among very lofty mountains, and during nine months in the year experiences great heats. Putrid and malignant fevers, frequently fatal, occur in the months of July, Auguſt, and September. The ſtreets are narrow and badly paved: and the houſes meanly built. It is defended by regular batteries, and the ordinary garriſon of the place is a company detached from the regiment of Caraccas. In time of war it is reinforced by other troops of the line, and the militia of Caraccas. The government have propoſed to make it merely a military poſt, and its commerce only a ſhipping place for the capital. Few merchants reſide here, the whole buſineſs being done at Caraccas. The commodities bought or ſold at Caraccas are ſent to Guayra only to be embarked. The population of

Guayra

Guayra conſiſts of 6000 perſons, of whom 3000 are in the gun-boats, 711 form the garriſon, or are in the guarda-coſtas or gallies. The almoner diſcharges, with reſpect to them, all clerical functions. The town has only one parochial church.

In conſequence of the ordinance for free commerce, iſſued October the 12th, 1778, Guayra is become a port of conſiderable trade. This port, and Porto-Cavallo, are regulated by an ordinance of 1798. In 1796 there arrived at Guayra forty-three veſſels of various ſizes, which imported more than to the value of three millions of dollars, the cuſtoms exceeding two hundred and eighty thouſand.

GUAY-TROUIN, Renè du, in *Biography*, a French naval officer, was born at St. Malo in 1673. His father united the profeſſion of a merchant to that of an adventurous ſeaman, and the ſon, willing to diſtinguiſh himſelf, went on board a privateer, and performed a number of heroic actions. In 1691, when he was only in his eighteenth year, he had the command of an armed ſloop, carrying fourteen guns, with which he obtained much ſucceſs on the coaſt of Ireland. Three years after he entered the river of Limerick, and carried off ſeveral veſſels; but falling in with four Engliſh ſhips, he was obliged to yield, and was taken a priſoner into Plymouth. In confinement he won the affections of a female who enabled him to make his eſcape, and in a ſhort time he appeared again on the coaſt of England, where he captured ſome prizes. In the year 1695 he took three rich veſſels on the Iriſh coaſt, and two Dutch ſhips on the coaſt of Spain: theſe ſucceſſes were followed by others ſtill more important. In 1696 he fell in with baron de Waſſenaer, who with three ſhips was eſcorting a fleet of merchant men, and took the baron with a part of his convoy. He preſented, in perſon, his priſoner to the king, and thereupon was removed to the royal navy, and appointed to the command of a frigate. In a few years afterwards he was made captain of a fifty-four gun ſhip, with which, it is ſaid, he took an Engliſh man-of-war of ſeventy-two guns. So brilliant was his career of ſucceſs, that in 1709 he was rewarded with letters of nobleſſe, the preamble to which records his having captured more than 300 merchant ſhips, and 20 ſhips of war. The moſt important of all his exploits was the taking of Rio Janeiro in 1711, which occaſioned a loſs to the Portugueſe of at leaſt a million ſterling. A penſion was now forced on him, he having in 1707 refuſed one that was then offered, requeſting that it might be granted to his ſecond captain, whoſe thigh had been ſhot off. "I," ſaid the gallant officer, "am ſufficiently rewarded, if I obtain the advancement of my friends." He did other important ſervices for his country, and died at Paris in 1736. His "Memoirs," partly written by his own hand, and partly by a nephew, were printed in one vol. 4to. 1740.

GUAZA, in *Ichthyology*, a ſpecies of *Labrus*; which ſee.

GUAZACOALCO, in *Geography*, a river of Mexico, which runs into the gulf of Mexico. N. lat. 18° 10'. W. long. 95° 26'.

GUAZACOCO, a town of New Mexico, in the province of Cinaloa; 28 miles S.W. of Cinaloa.

GUAZUMA, in *Botany*, Plum. Gen. 36. t. 18, the American name of a plant of the natural order of *Malvaceæ*, referred by Linnæus to the ſame genus as the chocolate-tree, *Theobroma*, but which is now, with great propriety, made a genus by itſelf. See Bubroma.

GUBA, in *Ancient Geography*, a town of Aſia, in Comagena, ſeated on the Euphrates, near a mountain, in which this river had a cataract, N.W. of Barſalium.

Guba, in *Geography*, a town of Aſiatic Turkey, in the province of Aladulia; 24 miles N.E. of Semiſat.

GUBBIO, or Eugubio, a town of Italy, in the duchy of Urbino, the ſee of a biſhop, held under the pope. It has ſeven churches and 21 convents; 33 miles S. of Urbino. N. lat. 43° 17'. E. long. 12° 35'.

GUBEL, a town of Bohemia, in the circle of Chrudim; 15 miles N.E. of Leutmiſchl.

GUBEN, a town of Luſatia, capital of a circle to which it gives name, ſeated on the Lubbe, near its junction with the Neiſſe; ſurrounded with walls in 1331. It contains three churches and an hoſpital: good wine is made here, and it has a manufacture of cloth; 22 miles S. of Francfort on the Oder. N. lat. 51° 57'. E. long. 14° 45'.

GUBER, a country in the interior of Africa, ſubject to Aſben. N. lat. 18° 15'. E. long. 8° 30'.

GUBERGRO, or St. Francisco, a river of Africa, which waters Benguela, and runs into the Atlantic; S. lat. 13° 30'.

GUBINAGUR, a town of Bengal; 28 miles N. of Dinagepour.

GUBINAPOUR, a town of Bengal; 15 miles N. of Mauldah.

GUDCARA, a town of Hindooſtan, in Bahar; 45 miles S.S.W. of Arrah.

GUDEGOW, a town of Hindooſtan, in Rohilcund; 7 miles W. of Biſſowlah.

GUDEMEL, a ſmall iſland on the W. coaſt of Scotland, E. of Oronſay. N. lat. 55° 59'. W. long. 6° 17'.

GUDENAH, a town of Hindooſtan, in Bahar; 40 miles W.N.W. of Chuprah.

GUDENFELD, a town of Pruſſia, in Natangen; 25 miles S. of Brandenburg.

GUDENSBERG, a town of Germany, in the principality of Heſſe-Caſſel; 8 miles S. of Caſſel. N. lat. 51° 12'. E. long. 9° 22'.

GUDGEON, in *Ichthyology*, the Engliſh name of the fiſh called by authors the *gobio*, and *gobius fluviatilis*. There are two ſpecies of the gudgeon. The firſt is our common river gudgeon, the Cyprinus *gobio* of Linnæus; which ſee. The ſecond is the leſſer river gudgeon, differing from the former not only in ſize but in being of a more tapering ſhape, growing very ſmall towards the tail, and being of a whiter colour and leſs ſpotted. The firſt is common in our rivers (ſee *Gudgeon* Fishing); the ſecond in thoſe of Germany, where it is commonly called a *wapper*.

Gudgeon, *Sea*. See Goget.

Gudgeons, in a *Ship*, are uſed for the eyes driven into the ſtern poſt, into which the pintles of the rudder go, to hang it on.

GUDGOW, in *Geography*, a town of Hindooſtan, in Baglana; 60 miles N.E. of Chandor.

GUDJARA, a town of Hindooſtan, in the circar of Gohud; 10 miles N.E. of Gohud.

GUDMUNDEN, a town of Sweden, in Angermannland; 18 miles N. of Hernoſand.

GUDRAJEGUNGE, a town of Hindooſtan, in Bahar; 3 miles W. of Arrah.

GUEBUCU, in *Ichthyology*, the name given by Marcgrave to the Xiphias *Gladius*; which ſee.

GUEBWELLER, in *Geography*, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the diſtrict of Colmar; 10 miles S.S.W. of Colmar. The place contains 2552, and the canton 8615 inhabitants, on a territory of 90 kiliometres, in 11 communes. A

canal was made from this town to New Briſac on the Rhine, by order of Lewis XIV.

GUEDRIER, DE ST. AUBIN, HENRY-MICHAEL, in *Biography*, was born in the dioceſe of Rouen in the year 1695. He purſued his maturer ſtudies at Paris, and was admitted a member of the Sorbonne in the year 1723. In 1736 he was choſen librarian, and obtained afterwards other preferment. He was very learned in the modern and ancient languages, and was deeply ſkilled in theology and morals. He was held in high eſteem, and for many years was conſulted as a reſolver of difficult caſes of conſcience. He died in 1742, leaving behind, as a memorial of his profound talents, "The Sacred Hiſtory of the Two Covenants," which had been publiſhed the year before his death, in ſeven volumes, 12mo. This work is ſaid to be a good exhibition of the harmony of the Old and New Teſtament hiſtories, interſperſed with diſſertations, criticiſms, and reflections.

GUEGUETENANGO, in *Geography*, a town of Mexico, in the province of Chiapa; 120 miles S.E. of Chiapa. N. lat. 16° 20'. W. long. 93° 16'.—Alſo, a river that runs into the Pacific ocean, N. lat. 15° 25'. W. long. 94° 37'.

GUEGETLAN, a town of Mexico, the capital of Soconuſco.

GUELDERLAND, DUCHY *of*, formerly a province of the Netherlands, bounded on the N. by Overyſſel, and the Zuyder ſea, on the E. by the biſhopric of Munſter and the duchy of Cleves, on the S. by the duchy of Juliers and Brabant, and on the W. by the ſtates of Utrecht and Holland. By the peace of Luneville, the Pruſſian and Auſtrian parts of Guelderland were ceded to France; and they form a portion of the department of Roer.

GUELDRES, a town of France, in the department of the Roer, and chief place of a canton in the diſtrict of Cleves. It is advantageouſly ſituated amidſt marſhes on the river Niers, whoſe waters fill the ditches; and it was formerly ſo ſtrongly fortified as hardly to be taken, except by famine. In the year 1794 it was taken by the French, and at the peace of Luneville ceded to that country; 72 miles S.E. of Amſterdam. The place contains 1556, and the canton 11,554 inhabitants, in 14 communes. N. lat. 51° 31'. E. long. 6° 10'.

GUELPHS, or GUELFS, a celebrated faction in Italy, antagoniſts of the Gibelins.

The Guelphs and Gibelins kept Germany and Italy in perpetual agitation during three centuries. The former ſupported the pretenſions of the popes, and the latter defended the rights of the emperor. Their riſe is referred by ſome to the time of Conrad III., in the twelfth century; by others, to that of Frederic I. and by others, to that of his ſucceſſor, Frederic II. in the thirteenth century, and by others again to the conteſt between Gregory VII. and Henry IV. about the cloſe of the 12th century.

The name *Guelph* is commonly ſaid to have been formed from *Welfe*, *Welfo*, on the following occaſion; the emperor Conrad III. having taken the duchy of Bavaria from Welfe VI. brother to Henry duke of Bavaria; Welfe, aſſiſted by the forces of Roger king of Sicily, made war on Conrad, and thus gave birth to the faction of the Guelphs.

Others derive the name Guelphs from the German *Wolff*, on account of the grievous evils committed by that cruel faction. Others deduce the denomination from that of a German called Guelfe, who lived at Piſtoye; adding, that his brother, named *Gibel*, gave his name to the *Gibelins*; under which head the reader will find a more ample account of the origin and hiſtory of thoſe celebrated factions.

GUELTAS, in *Geography*, a ſmall iſland in the Engliſh channel, near the coaſt of France. N. lat. 48° 51'. W. long. 3° 15'.

GUEMENE', a town of France, in the department of the Lower Loire, and chief place of a canton, in the diſtrict of Savenay; 9 miles N. of Blain. The place contains 3585, and the canton 7300 inhabitants, on a terrritory of 240 kiliometres, in 5 communes.—Alſo, a town of France, in the department of Morbihan, and chief place of a canton, in the diſtrict of Pontivy. The place contains 1325, and the canton 14,667 inhabitants, on a territory of 297½ kiliometres, in 9 communes.

GUEPARD, in *Zoology*, the name given by Buffon to the FELIS *jubata*; which ſee.

GUEPIER, in *Ornithology*, the name given by Buffon to the MEROPS *apiaſter*; which ſee.

GUER, in *Geography*, a town of France, in the department of Morbihan, and chief place of a canton, in the diſtrict of Ploermel, and 9 miles E.S.E. of it. The place contains 4800, and the canton 10,658 inhabitants, on a territory of 160 kiliometres, in 5 communes.—Alſo, a river of France, which runs into the Engliſh channel, N. lat. 48° 45'. W. long. 3° 28'.

GUERANDE, a town of France, in the department of the Lower Loire, and chief place of a canton, in the diſtrict of Savenay; 36 miles W. of Nantes. The place contains 7222, and the canton 11,831 inhabitants, on a territory of 217½ kiliometres, in 6 communes.

GUERCHE, LA, a town of France, in the department of the Cher, and chief place of a canton, in the diſtrict of St. Amand; 7 miles N. of Sancoins. The place contains 1003, and the canton 6069 inhabitants, on a territory of 235 kiliometres, in 9 communes.—Alſo, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the diſtrict of Vitré; 9 miles S. of Vitré. The place contains 3578, and the canton 14,258 inhabitants, on a territory of 212½ kiliometres, in 11 communes. N. lat. 47° 57'. W. long. 1° 10'.

GUERCINO DA CENTO, in *Biography*. See BARBIERI.

GUERET, GABRIEL, a lawyer and man of letters, was born at Paris in 1641, and admitted an advocate in parliament before he was twenty years of age. He was diſtinguiſhed at a much earlier period by his literary publications, of which the firſt was entitled "Les Sept Sages de la Grèce." His "Entretiens ſur l'Eloquence de la Chaiſe et du Barreau," contains judicious reflections. But the works on which his literary reputation is chiefly founded, are entitled "Le Parnaſſe Reforme," and its ſequel "La Guerre des Auteurs." Theſe are both written in a ſatirical ſtyle, and have been much applauded. As a lawyer he was chiefly diſtinguiſhed for his conſultations; and for the part which he took in the compilation of "Le Journal du Palais," conſiſting of a well digeſted collection of the arrets of the French parliaments. He likewiſe publiſhed an edition of Le Prêtre's "Arrets Notables du Parlement," which he enriched with notes and additions.

GUERET, in *Geography*, a town of France, in the department of the Creuſe, and principal place of a diſtrict, ſituated near the ſource of the Gartempe, between two mountains, at ſome diſtance from the Creuſe. The place contains 3125, and the canton 12,963 inhabitants, on a territory of 247½ kiliometres, in 13 communes. N. lat. 46° 10'. E. long. 1° 57'.

GUERICKE, OTTO, in *Biography*, an able experimental philoſopher, was born in the year 1602. Of his early life

nothing is known, but he was counſellor to the elector of Brandenburg, and burgomaſter, or conſul of Magdeburg; he is, however, better known and more diſtinguiſhed by his philoſophical diſcoveries than by the honours to which he was advanced in the ſtate. To him we are indebted for the diſcovery of the air-pump, the honour of which has ſometimes been given to Mr. Boyle, but this excellent man readily acknowledged that he was indebted to the experiments of Guericke for being able to bring his own machine to perfection. This philoſopher invented the braſs hemiſpheres to illuſtrate the preſſure of the air, and, it is ſaid, he made a pair large enough, and ſo accurately exhauſted them, that the power of ſeveral horſes acting at the handle of each was unable to draw them aſunder. He was the inventor of an inſtrument to ſhew the variations in the ſtate of the atmoſphere, which anſwered the purpoſe of a barometer, till a more perfect inſtrument was executed. He was author of ſeveral treatiſes in experimental philoſophy, the principal of which is entitled "Experimenta Magdeburgica," 1672. He died at Hamburgh in the year 1686.

GUERITE, in *Fortification*, a centry-box; being a ſmall tower of wood or ſtone, placed uſually on the point of a baſtion, or on the angles of the ſhoulders, to hold a centinel, who is to take care of the ditch, and watch againſt a ſurpriſe.

GUERKIN, or GHERKIN, a kind of cucumbers for pickling.

GUERNADUAS, in *Geography*, a town of the iſland of Cuba; 32 miles E S.E. of Spirito Santo.

GUERNSEY, an iſland lying within the bay of St. Malo, is about 7 leagues N.W. from Jerſey, 20 from Weymouth, 5 from Alderney, and about 7 from the French coaſt of Normandy; and, with the neighbouring iſlands, is encompaſſed by the Britiſh channel. Its greateſt length is about 13 miles, and breadth more than eight. In the Itinerary of Antonine it is named *Sarnia*, a word from which has, through the languages of Gaul, been derived *Garnſay*, *Garnezay*, and *Guernſey*. This iſland, with Alderney, Sark, Herme, and Jethou, forming one bailiwick, may be ſuppoſed to have ſhared in the circumſtances of the neighbouring continent. As part of the duchy of Normandy, they were veſted, at the conqueſt, in the crown of England, a parcel of which they have yet continued, notwithſtanding the ſeveral efforts of the French for their recovery. The lands of this iſland are, on the S. and S.W., very high, and full of abrupt precipices, interſected by ravines towards the ſea, affording extenſive proſpects of the ocean, Jerſey, and the coaſt of France, from cape La Hogue ſouthward. In many of the ravines, the views of the granite cliffs and mountainous heights are often grand and romantic, and ſometimes riſe to a degree of ſublimity little to be expected, and ſeldom met with. On the N. and E. the coaſt is low, and diverſified with a ſucceſſion of bays, ſeparated by rocky head-lands, and without, at various diſtances, the ſunken rocks and crags, by which the iſland is ſurrounded, form at once an appearance terrific and pleaſing, ſince they inſure, aided by the ſeveral currents, an almoſt certain immunity from attack. Every part of the coaſt is fortified with ſtrong batteries and breaſt-works, beſides the regular fort and citadel, with a ſuitable eſtabliſhment of regiments of the line and militia for its defence. Among the curioſities of the coaſt may be reckoned *La cave Mahie*, on a level with the ſea, at the foot of a rocky ſteep, near Prevolet point; it is above 200 feet in depth, and from an entrance of nine or ten feet, and ſix in height, it extends to 50 or 60 in height and breadth, ending in granite points. The whole foundation of the iſland is of this ſubſtance, and ſeveral of its heights conſiſt of conical aſcents of the granite ſub-ſtrata, raiſed, as it were, by a power acting vertically, not unlike a volcanic effort.

The climate, like that of the weſt of England, is ſubject to moiſt winters and ſprings, with a ſuperabundance of high winds. The ſummers are warmer than in England, and ſtrangers are, in ſome degree, ſubject to the diſeaſes of hot climates. The face of the iſland is diverſified by moderate hills and vallies, covered with numerous encloſures, and ſeparated by intricate roads, and watered with ſeveral ſtreams, which, collected, turn over-ſhot mills. Agriculture, the conſtant employment of the inhabitants of the country, is carried on with care and diligence; for, unaided by machines, every rood of ground in Guernſey may be ſaid to maintain its man. The ſeats of the gentry, and the farm houſes and cottages, (from whoſe appearances the comforts of a country may be eſtimated,) lie agreeably ſcattered among orchards and gardens, affording the traveller a variety of gratifying views: he muſt alſo find pleaſure in obſerving the cleanlineſs and induſtry of the peaſantry, and the ſatisfaction generally found in all ranks; yet, perhaps, ſhould the ſtranger expect much accommodation, or even civility, he may be diſappointed. In this, however, it is not certain that the inhabitants differ from thoſe of other remote places.

There are ten pariſhes in the iſland; thoſe of the vale are ſeparated by a ſandy flat, covered formerly, at high water, for many hours, and called the Bray, having the bay of St. Sampſon, and another, called Grand Havre, at each extremity, where enbankments have been caſt up, an undertaking of the preſent lieutenant-governor's, which promiſes to bring a conſiderable tract into cultivation. The produce of this iſland differs little from that of the weſtern parts of England. Their fruits are generally very fine. Pigs are conſtantly fed, during winter, with parſnips. Butter, pork, and veal, are in the higheſt perfection; and the ſeas produce an abundant ſupply of fiſh.

Among the marine productions is found the ſea-ear, a ſhell-fiſh, eſteemed a delicacy; the beautiful ſhells of which are frequently ſold under the name of iris-ears. The aphrodita-aculeator, or ſea-mouſe, is ſometimes caught by the fiſhermen; it has the peculiar property of paſſing the water through the whole length of its body at each reſpiration, which it projects in one or two ſtreams from the tail, and the protuberances at the ſides are furniſhed with briſtles inſtead of feet. It is extremely tenacious of life; and, on account of the changeable colours of the down with which it is covered, and its extraordinary habits, is intereſting and beautiful. There are alſo to be found, adhering to the rocks when the tide is out, various ſpecies of animal flowers, or ſea-anemonies. Theſe creatures, beſides their tentacula, ſeem little more than a caſe, or alimentary-canal, which yet perform all the offices of digeſtion; they have alſo the power of motion: and other properties deſerving inveſtigation.

The inhabitants of Guernſey were originally Norman French, and may yet be ſo eſteemed. They ſpeak a provincial dialect, in which are found many old terms. Of the ancient Gallic inhabitants of Guernſey memorials are to be found in two remaining aſſemblages of ſtones, there called Druids' altars, by us *Cromlecheu*. They are placed in open and formerly dreary parts of the coaſt, on a part of which, called la Crocq, there is a tall ſtone, whence it is ſaid the name is derived; but what may have been deſignated by *the hook* muſt be now uncertain, and the Celtic antiquary ſhould be cautious leſt the hand of the quarrier may not have recently formed the objects of his favourite ſpeculation. Of Guernſey under the Franks, or old Gothic inhabitants, ſcarcely any traces remain, unleſs in the names of certain places derived

from ſituation: theſe are met with in Lihou, Hournette, Jethou, Hougathe, Hammeau, Haye, Vaude, &c. whoſe alliance with the Francic language is evident. There are to be found in Guernſey, as in moſt other places, many cuſtoms by which the inhabitants are peculiarly diſtinguiſhed. They may yet be ſaid, as it was noticed by the hiſtorian, Malmſbury of their anceſtors, to be moderate and abſtemious, yet fond of external appearance. The ſtranger is ſurpriſed at the ſize and handſome exterior of the ſeats and farm houſes, yet in the latter there is generally a want of comfortable finiſh. The Guernſey farmer, whoſe feudal character is fixed, is contented with plain walls, an earthen floor, and his almoſt every room equipped with the convenient apparatus of the kitchen. His uſually ſpacious entrance is crowded with barrels of cyder, monſtrous ſhining braſs kettles, and the furniture of his horſes. The food of the ordinary rank is a ſoup made of cabbage, greaſe, flour, and a few ſlices of green bacon: this diſh, improved with a ſmall portion of beef, is not only the holiday food, but finds its place on the retired table of the ſuperior. The eater of ſoupe à la graiſſe is always known by his bilious aſpect, the general complexion of the native inhabitants. Theſe ſeldom tranſgreſs the obſervance of an exact ſobriety, to which the greater mini attaches, ſince liquors are ſo eaſy of acceſs; and here they are in exact oppoſition to the habits of the Engliſh ſettler, who, but too frequently leaving his country to avoid the preſſure of the laws, is not often accompanied by many of its virtues. Their affection to their children, and unalterable attachment to their parents, whom they cheriſh to the lateſt period, are proofs that theſe iſlanders yet retain a portion of primæval ſimplicity. Their parſimony produces effects much to be deſired among the lower orders of this country. A cottage, a garden, a field, an orchard, appear to be in Guernſey, at leaſt, the patrimony of every family, and every one is enabled to improve his poſſeſſions. The amuſements are chiefly dancing on the holidays, at the principal annual feſtivals, riding in parties in the month of Auguſt, when the roads are crowded with cheerful cavalcades, a cuſtom ſuppoſed to be derived from the abbot of St. Michael going through the country in proceſſion, or from the proceſſion of Corpus Chriſti, which is leſs probable, as that feſtival happens uſually in June. Viſits are in the town a common amuſement. The company break up in the evening at eight, when the ſtreets are on a ſudden filled with ladies and lanthorns. Several ſuperſtitions are found to exiſt. Witchcraft is credited. A man was very lately pilloried as a witch-finder; and certain tall, meagre, old women in remote country reſidences, are treated with grave obſervance, leaſt their cattle ſhould ſuddenly die or their cyder turn ſour. And it is not long ſince a ſomething like our Cock-lane-ghoſt was played off by ſome enthuſiaſts, in which a deſcent of fire, upon the bed of a child, was a principal part of the farce, which continued for ſeveral weeks. A pretended ſpectre la bete la tua alſo infeſted the town for ſome time every winter about Chriſtmas. Theſe ſpectres are common enough in France: at Tours they have le roy Hugon, who walks in the night, as does at Paris le moine Bouru, and at Toulouſe le malo beſtio.

The *laws* are the feudal, ameliorated by time, which has worn down moſt of the oppreſſive cuſtoms of that ſyſtem. They are adminiſtered by the bailiff and jurats forming the royal court, and are chiefly Norman, to be found in the work of Terrein. In criminal caſes, it ſhould ſeem as if the ſentence was rather guided by the judgment of the aſſeſſors than by any written law; and in caſes of bankruptcy our own precedents are the uſual reſort. An Engliſh jury is not known in Guernſey; yet here is to be found a due adminiſtration of juſtice, among a numerous population fully at eaſe for the ſecurity of life and property. Advocates, and the glorious uncertainty of the law, are not ſtrangers in the iſland. It has one or two petty-foggers, ſignificantly termed chicaneurs, and ſuits can be protracted, but in general a decent riddance is made. Law is cheap, and it is not poſſible to conceive perſons more addicted to litigation than the inhabitants of Guernſey. The mode of acquiring lands by the payment annually of a ſtipulated number of quarters of wheat is remarkable; that it ſhould be commodious depends on thoſe who make the rate in lieu, which is always paid in money. The care taken of the dowries of women is highly creditable, though it proves not unfrequently prejudicial to the heirs. In caſe of ſecond marriages an intelligent abſtract of the laws and the privileges of the meetings of the bailiff and jurats, the clergy and douzainiers, or repreſentatives of the people, in the preſence of the lieutenant governor, called the States of the Iſland, may be ſeen in Dicey's Hiſtory of Guernſey.

The preſent predominating ſyſtem of religion in the iſland is that of the church of England, though not unmarked with certain traits of the diſcipline of Geneva, which was pertinaciouſly held till the reign of Charles II. The followers of the late John Weſley are very numerous and buſy, and the din of their meetings is heard throughout the country. Calviniſm, diſtinct from the Engliſh church, has at preſent but a ſlight hold in the iſland. There are a few ſectaries of other denominations, and the number of emigrants from France, and labourers from Ireland, form a congregation of Catholics, which is freely tolerated.

Society in Guernſey is conſidered as divided into three claſſes: of theſe, the firſt ſeems to claim an excluſive right to conſequence and office. Theſe are the ſeigneurs des fiefs, the merchant, ſome of the clergy and lawyers, with military and naval officers, and whatever it ſhould ſeem could in Guernſey entitle the poſſeſſor to the rank of gentleman; yet this rank is ſo capriciouſly diſtributed, that we find a moderate ſhop kept by gentlemen of the firſt claſs, with an excluſion to perſons of ſuperior merit from their routs and aſſemblies. The ſecond claſs is formed of thoſe who have thriven, yet not admitted to the ſociety of the firſt; and the third, or loweſt, includes the farmer and the peaſant, the artiſt and artificer, whoſe want of qualification no merit or property can compenſate: and thus the nobility, the title theſe petty folks aſſume, are diſtant and haughty, and the inferior rank, miſuſed and diſregarded, are pliant, ſervile, ſelfiſh, and ſubtle. Among the ſeats in the iſland that of Harpe de Puye is the moſt ancient. It is remarkable for a projecting turret at each corner, named Promp ſur le coin, a favourite old French faſhion in building. The ſituation it occupies is in a pleaſant valley, and the lands and woods about it are adorned in a ſtyle not quite modern. This old ſeat reflects more credit on the anceſtry of Guernſey than any other of the more early habitations, though ſeveral retain ſomething of the old baronial obſcurity. There are, however, many good modern ſeats, which are neither inelegant, or in taſte altogether wanting in the diſpoſal of the grounds about them.

There were anciently four caſtles in the iſland; of theſe *Caſtle Corner*, ſeated on a rock, about a quarter of a mile from the ſhore, near the town, is the ſuperior. It is ſcarcely acceſſible but on one ſide, and is formed wholly of granite. The original foundation of theſe fortreſſes is given to duke Robert of Normandy: this is noticed in the reign of Edward I. and Edward II. &c. on account of the attempts made by the French to repoſſeſs the iſland, and it has been once taken, and, for ſome time, held by them. It

anciently

anciently conſiſted of a keep, now made into caſemates, an outer wall of great thickneſs, flanked by ſeveral machicolated towers. In this caſtle the lieutenant governors had their reſidence. In it are ſeveral wards, united by gloomy paſſages; and it muſt have been a place of great ſtrength, although it did not occupy the whole defenſible parts of the rock. In the time of queen Elizabeth it was augmented with a lower line of curtain and baſtions. Barracks and accommodation have ſince been formed for a numerous garriſon, and it is well defended by a conſiderable number of heavy artillery. Here was the common priſon of the iſland both for debtors and felons, a foul hole, diſgraceful to humanity. This caſtle has loſt much of its ancient appearance; a late engineer having ſtript ſeveral of the towers of their machicolations for making repairs. There was beſides a tower of conſiderable height in the centre of the keep, about which were ſeveral houſes, as appears by one of Groſe's views, publiſhed in 1777. Theſe were called the new buildings in 1672, when an exploſion of gunpowder took place, and conſiderably damaged this ſtrong hold. There are two other views from the ſame hand, of that year, in which the caſtle is ſeen without thoſe parts, nearly as it is at preſent. The *Caſtle in the Marſhes* bears about it an appearance of high antiquity. It is ſurrounded by a double wall of granite, roughly laid with an outer and inner ditch, and a keep in the Norman form. It is at preſent laid out in garden ground, and belongs by office to the governors. The *Vale caſtle*, placed upon a commanding eminence near St. Sampſon's harbour, is of ſome antiquity; as it is mentioned ſo long ſince as the year 1114, when Renault Montſannape was governor. A ſtrong circumſcribing wall, with ſome flanking towers, comprize, with the portal, the whole exterior of this once reputed ſtrong fortreſs. Within are barracks for the garriſon: it has ſeveral pieces of cannon placed upon its ramparts, commanding a paſſage called the ruſſel. Near the aſcent to this caſtle is a burial ground belonging to the Ruſſians, who were in this iſland in the year 1800, which was remarkable for the number and various forms of the croſſes they had left on the graves of their deceaſed companions. There were, beſides theſe, till lately, ſome remains of a caſtle at Rocquane, ſeated on a ſmall rocky eminence at the bottom of a bay of the ſame name, on the weſtern coaſt. It was denominated a fort in the year 1114, under the government of Renault Saliſbury. It has been ſince diſmantled, and formed into a powerful battery of heavy guns. There was yet in the iſland another fortification called the caſtle du grand Geoffroy, taken down about 1203, when the church of St. Mary of the caſtle was built upon its ſite, which took beſides the title of Notre Dame, *de la délivrance*; indicating, as it ſhould ſeem, this grand Geoffroy no very good neighbour, and with his caſtle, happily got rid of. This diſtrict was alſo in 1114 and 1203 termed La Paroiſſe du grand Sarazin. Within it we find the Rohais, an eſtate, not unlikely ſo denominated after a town in Paleſtine, which is mentioned by Reland.

The Chriſtian religion is ſaid to have been planted in this iſland by St. Sampſon and St. Magloin, Britiſh biſhops, about the year 566; but this diſtrict does not ſeem to have been ſeparated into parochial lots for many centuries after. The earlieſt mention of a religious fraternity is in 1111, when Claude Panton, hermit of Lerne, and his holy brethren, are noticed as applying for the conſecration of the church of St. Sampſon. Although at this time, and before, it is probable the abbey of St. Michael in the Vale had been founded, this religious houſe had its court and feneſchal: and the proceſſions of its abbot and monks are frequently noticed; but of what order it was, like the form and paſt conſequence of buildings, is forgotten; nothing more remains of it than a ſmall portion converted to a cottage on the edge of the bray. There are beſides ſome pointed arches on the ſouth wall of the cemetery of the Vale church, likely a part of its chapel, ſaid to have been on the ſouth ſide of the pariſh church, with the proceſſional way lying between. Near this is a cauſeway of large ſtones, called the *devil's bridge, viz.* Pont du Val, which paſſed acroſs the bray. The paſſage of the ſea acroſs this flat ſeems to have taken place about the year 1204, when at a court of chef plaids for the vale, held on the 14th of October that year, a remonſtrance was made on the part of the prior and his brethren, and of the pariſhioners of that pariſh, and of St. Sampſon's, that they were greatly injured by the ſea having broken in and deſtroyed the paſſage between them, ſo that they could not paſs in proceſſion, &c. and praying permiſſion to erect and ſupport a certain bridge. This record points out the date of the raiſed cauſeway named St. Sampſon's bridge, as well as the time when the bray had been ſo far formed by the encroachments of the ſea, as to become a ſerious inconvenience to the inhabitants of the vicinity.

A ſecond monaſtic inſtitution was founded about 1114, in the ſecluded iſland of Lihou, a ſpot ſeparated from the coaſt of Guernſey by a channel paſſable at low water, now the property of a Mr. Muchant, and ſerving the purpoſe of a warren for rabbits. Here are yet the remains of the priory church of our lady of the Rock, which had been dedicated the 15th of Auguſt in the above year by Cloitare de Belangere, biſhop of Coutance, at the requeſt of Machoire Lublin, then prior. They conſiſt of the longitudinal half of the ſimple ſtructure, with which thoſe monks were contented, amounting to little more than a wall broken by a few plain arches, and bearing about one-third of the highly pointed vault which had covered this building. Several foundations of the priory walls are found in the vicinity: it was ſeated near the ſouthern ſhore upon the ſea. The only building now on this iſland is a ſummer-houſe in ruins. To the weſtward of Lihou is yet a rocky and almoſt iſolated headland. Here nature puts on one of her moſt terrific appearances; all is barren; craggs and rocks laved perpetually by an apparently boundleſs ocean: a cauſeway, the work of thoſe poor monks, paſſes from Lihou to the oppoſite ſhore; it is dry at ſpring ebbs, when it appears formed of pieces of red granite, united ſo firmly by the excellence of the cement, that it is yet, in many places, whole, after ages of diſuſe and neglect. It leads to the bottom of a high hill, of a conical form, named Le Ree. Of theſe eminences, ſo like volcanic productions, ſeveral could be pointed out in the iſlands of Guernſey and Alderney, as well as Jethou: the latter ſeems thus wholly formed. What further deſerves remark is, that on the coaſts from this point to the ſouthward, till the aſcent to Pleinmont, the ſea makes viſible encroachments upon the land, where the ſhore is not defended by rocks; while from thence northerly, vaſt quantities of ballaſt are continually waſhed up, forming a bulwark againſt the ocean, and an acceſſion to the iſland.

Moſt of the eccleſiaſtical benefices in Guernſey ſeem to have been appropriated to religious houſes, and at the change of religion, the great tythes falling into the hands of the crown have conſtituted a part of the governor's ſalary. The churches to which theſe benefices were annexed yet remain, and the dates of their dedications may be ſuppoſed nearly to form thoſe of the buildings themſelves, and are given in the following order. St. Sampſon 1111; the Vale church 1117; Torteval 1130, built by Philip de Carteret in conſequence of a vow made in a violent ſtorm; St. Sauveur's, 1154; the Foreſt Church, 1168; St. Peter au bois, 1167;

1167; St. Martin's, 1199; St. Mary of the Catal, 1203; St. Andrew's, 1284; St. Peter's Port, 1312. Theſe churches are of granite, and from the hardneſs of the material, what ornaments they poſſeſs, muſt have been the effect of much labour and perſeverance. They are remarkable for being covered generally with a very highly pointed and continued vault, ſtrengthened in parts by munnions, over which are laid the roof and covering. Within they have little that is intereſting; the windows having been ſtript of their munnions, beſides being unſightly, from the cuſtom of painting the joints of the maſonry, and uſing the means to give them an exterior appearance. The architecture of theſe edifices is in other reſpects Gothic, except a few inſtances. There is a circular groined vault in the chancel of the Vale church, about which are Norman zigzags. The churches of St. Peter au bois, and St. Sauveur, are ſomewhat handſome ſtructures, and do not appear in a ſtyle quite ſo early as the dates annexed to them above; and it is remarkable, that though the forms and proportions of the mouldings throughout the interior of St. Peter's are Gothic, yet it is not recollected that a pointed arch occurs through that building. The exterior of the town church is handſome; its tower is an ornament from the pier and road, and its porch remarkable for the depth and extent of its mouldings, as is the porch of St. Martin's for the ſculptured foliage with which it is decorated. In the town church are ſome good modern monuments; in the reſt but few are to be ſeen. The moſt ancient is a braſſleſs ſlab in the Vale church; yet the cemeteries are ſufficiently full. The inſcriptions on the grave-ſtones of the natives run all nearly in the ſame ſtrain, every one departs to the Lord, and unleſs a ſeigneur du fief reſts below, this ſtrain is never interrupted. St. Peter's Port, the only town in the iſland, ſeems to owe its origin to the protection afforded from the vicinity of the caſtle, and it muſt, from the ſize and handſome condition of its church, have been in a flouriſhing ſtate in the year 1312. It is of late much increaſed, having originally conſiſted of a narrow ſtreet of high houſes, but now it ſtretches acroſs a ravine, over ſeveral hills, and upon the heights by which it is ſurrounded. The ſtreets are in the lower parts irregular, narrow, and dirty, and compoſed of a mixture of good and mean houſes and ſhops, which are numerous and well-ſupplied before the ſmuggling was ſuppreſſed by a late act of parliament (which, with privateering, made the great concern of the place): the ſtreets were filled with paſſengers and carts, with all the buſtle of trade, the river with ſhipping, and the key always thronged. There are but few public buildings worth attention in this town. The new court-houſe is a neat granite ſtructure, fitted with ſuitable offices, where the records are kept, but except a few detached parchments and Elizabeth's charter, include a period of little more than two centuries, in which the contracts have been entered into books, previous to which they were kept in rolls, and ſaid to be unfortunately loſt. The fate of the eccleſiaſtical records of the iſland is remarkable; the clergy of its former religion having, as it is reported, packed them in *caſks*, with their church plate, and conveyed them to Normandy, after having lain ſome time buried in a chapel, at a diſtant part of the vale. The memorial, however, called La dedicaſe des Egliſes, has eſcaped, and contains many circumſtances of much curioſity, which could be better relied on, did it not ſeem to be either tranſlated, or probably reformed by the preſbytery, whoſe language it rather ſpeaks than that of the pontificate. But to return to the town, a new priſon has been lately erected, for which the debtors goal at Mancheſter ſeems to have ſerved as a model, and which, much to the credit of the preſent leading men, has the great advantages of air, ſpace, and convenience. The hoſpital, or work-houſe, an inſtitution of conſiderable benefit to the town, is well regulated by its own peculiar laws, and ſupported by an endowment, together with a moderate rate *per* quarter on lands and houſes. Here not only the poor are maintained, but the diſorderly confined and corrected; beſides, allowances are granted to the induſtrious while under temporary affliction or neceſſity. The general charity of the iſland is beſides extenſive, and ſeldom divulged. In paſſing through the ſtreets of the town, ſeveral ancient houſes will be perceived with their ſtories overhanging, as found in ſeveral parts of London, and like them have certain ſculptured decorations. On a corbel of one of theſe, in the high ſtreet, occurs the ſymbol I.H.S. which muſt have been fixed ſome time at leaſt before the reign of Edward VI. At the back of the ſame ſtreet are the keys and the piers, a vaſt maſs of rough maſonry, formed with large blocks of granite, and carried out into the harbour: it includes a ſpace of ſeveral acres. The walls forming this incloſure are paved, and, having the advantage of parapets, form a walk, the reſort of men of buſineſs, politicians, and loungers. Beyond is the harbour and road, which is expoſed towards the S.E., but an open ſpace or carfour at the end of the principal ſtreet, ſerving the purpoſe of an exchange, an accommodation, it is a matter of ſurprize, a trading community ſhould be ſuffered to want. In this ſtreet is kept the market for fiſh; but for meat and vegetables, a large building has been erected in an open ſquare. Commodities are here weighed at the king's ſcales, with ſtandard weights; and a ticket of the quantity is delivered to the purchaſer. There are alſo frequent viſits made by the proper officers, who ſeize for the uſe of the hoſpital whatever is defective in weight and quantity. Above the market-houſe is a large and handſome pair of rooms for the public aſſemblies and entertainments, which are held monthly during the winter ſeaſon. There is beſides a play-houſe, and once, in two or three years, it is allowed to be occupied by a company of actors for ſeveral months, who meet with good encouragement: and they are ſometimes regaled by equeſtrian feats, fireworks, and concerts. From the level of the market, one hundred ſteps leads up the ſide of the ravine to the new town, where are many good and open ſtreets, beſides George Row, conſiſting of ſeveral elegant houſes. Near this is a road called La Battaille, in memory of an engagement which took place in ſome of the French aggreſſions, who were here worſted, and afterwards driven out, and about this ſpot ſeveral French coins have been found. On the ſame level is L'Hivreure, where are ſeated the public walks, frequented by perſons of all conditions; beſides, they ſerve often the purpoſe of military parade. Proceeding thence towards the town, we come to a large houſe named the College, a foundation of queen Elizabeth, for teaching the claſſics, and which yet, in ſome meaſure, continue to be taught. Near this is the government-houſe, a handſome ſtructure; it is at preſent the habitation of ſir John Doyle, bart. whoſe good ſenſe and manly conduct, united to his amiable manners, have conciliated and made his own every rank in the iſland. By this gentleman's unremitting attention, the fortifications have been increaſed and diſpoſed with a maſterly ſolicitude: the iſland has been traverſed with new roads, and every means purſued by which the charge committed to his care could be ſtrengthened and defended

With reſpect to the laws that govern this iſland, ſee ALDERNEY.

GUERNSEY *Lily*. See AMARYLLIS.

GUESCAR, in *Geography*. See HUESCAR.

GUESCLIN, BERTRAND DU, in *Biography*, conſtable of France, in the 14th century, was born in Britanny in 1311.

1311. He was the ſon of a noble of that province, but ſo completely neglected in his youth, that he was never able to read or write. When he arrived at manhood, he was perpetually engaged in quarrels and in combats with his cotemporaries, and he grew up very hard featured and plain, but manly and vigorous. "I am too ugly," ſaid he to one of his companions, "ever to pleaſe the ladies, but I can at leaſt make myſelf feared by the enemies of my king." He accordingly devoted himſelf to the profeſſion of arms, and followed it with great ſucceſs, obtaining many important advantages over the Engliſh in Britanny. After the battle of Poictiers, in which John, king of France, was made priſoner, Du Gueſclin flew to the ſuccour of the regent Charles, heir of the throne, and gave him very important aſſiſtance in recovering many ſtrong places in the hands of the enemy. He was raiſed to the command of the royal army by Charles V. in 1364, and performed ſuch ſervices, as were repaid with high honours by his ſovereign. He was afterwards ſent to the aſſiſtance of Charles De Blois, competitor for the duchy of Britanny againſt Montfort, when Charles, raſhly engaging againſt his advice, was killed at the battle of Auray, and Du Gueſclin, covered with wounds, was made priſoner by the Engliſh. He was ranſomed at a high price; and was again taken captive at the battle of Navarette, in 1367. The Black Prince, diſcontented with his ally Peter the Cruel, gave Du Gueſclin his liberty, who immediately entered into the ſervice of Henry de Traſtamare, and was the chief agent in fixing him on the throne, in oppoſition to his enemy Peter. He received for his reward very ſignal honours from his ſovereign, was made conſtable of Caſtile, duke of Molina, and count of Burgos. He was engaged, after this, in ſeveral expeditions, which did him honour as a warrior and hero: the laſt was in the ſouthern provinces, where the Engliſh had rallied their forces, and had laid ſiege to Chateau-neuf-de-Rendan, in Auvergne. Here he was attacked with a mortal diſeaſe, and perceiving his end to be approaching, he ſummoned his principal officers to his bed-ſide, ſtrongly recommended to them never to treat as enemies, labourers, women, children, the aged and infirm, teſtifying the moſt unfeigned regret at having himſelf not always obſerved theſe rules. He expired in the year 1380, at the age of ſixty-nine. The Engliſh garriſon, which had conditioned to ſurrender at a certain time, if not relieved, marched out the day after his death, and the commander reſpectfully laid the keys of the fortreſs on his coffin. His body was conveyed to St. Denis, and depoſited in the tomb next that of the king.

GUESDA, in *Botany*, is properly the name of woad; but it is alſo uſed by ſome for the *lutum*, or *lutea herba* of the Romans, and *cymene* of the Greeks. This is an error in too many of the old authors, though ſo palpable that one would have thought nobody could have run into it; the *lutum*, or *cymene*, having been always uſed to dye yellow, and the *glaſtum* or *gueſda*, to dye blue; and the characters of the *lutum* or *cymene*, plainly ſhewing it to be our *geniſtella tinctoria*, or dyer's weed, but not at all agreeing with the *glaſtum*, or woad.

GUEST-ROPE, on *Ship-board*, is that rope by which the boat is kept from *ſteering*, or going too much in and out, as ſhe lies in the tow of a ſhip.

GUEST-TAKERS, or GIST-TAKERS. See AGISTOR.

GUET. See WATCH.

GUETA, or HUETA, in *Geography*, a town of Spain, in New Caſtile, ſituated on a ſmall river, and containing 10 pariſhes, 7 convents, and three hoſpitals; and ſaid to be founded 930 years B.C.; it derived its preſent name, ſignifying the moon, from the Moors, and it was taken from them by Alphonſo VI.; 43 miles E. of Madrid. N. lat. 40° 20'. W. long. 3° 1'.

GUETARIA, a ſea-port town of Spain, in the province of Guipuſcoa, with a good harbour at the mouth of the Orio; 9 miles W. of St. Sebaſtian.

GUETTARD, JOHN STEPHEN, in *Biography*, was born at Eſtampes on the 22d of September 1715. He was admitted a doctor of the faculty of medicine of Paris in 1742. He diſtinguiſhed himſelf in the ſtudy of botany and mineralogy, and his reputation procured for him admiſſion into the Academies of Science of Paris, Stockholm, Florence, and Rochelle, as well as the ſituations of cenſor royal, and of keeper of the cabinet of natural hiſtory belonging to the duke of Orleans. He travelled much in queſt of knowledge; and he publiſhed in the collection of the Academy of Science, and printed in two quarto volumes nearly two hundred memoirs, on different parts of natural hiſtory. He likewiſe publiſhed ſome "Obſervations on Plants," in 1747. He lived to the age of 71. Hutchinſon Biog. Med. Eloy.

GUETTARDA, in *Botany*, named by Linnæus in honour of John Stephen Guettard, M. D. member of the Academy of Sciences at Paris, author of a local French Flora, entitled "Obſervations ſur les Plantes," in two vols. 12mo. Paris, 1747, and of a great number of valuable treatiſes on Botany, as well as Entomology, publiſhed in the Memoirs of the above Academy. He died in 1786, aged 71.—Linn. Gen. 492. Schreb. 641. Willd. Sp. Pl. v. 4. 398. Mart. Mill. Dict. v. 2. Juſſ. 207. Lamarck Illuſtr. t. 154. Gærtn. t. 36. (Haleſia; Brown. Jam. 205.) —Claſs and order, *Monoecia Heptandria*, Linn. *Monoecia Hexandria*, Schreber and Willdenow. *Pentandria Monogynia*, Lamarck, which laſt is perhaps moſt juſtifiable by analogy, but the different ſpecies differ, as well as vary, in number of ſtamens. Nat. Ord. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, cylindrical, ſhort, ſlightly waved or toothed, deciduous. *Cor.* of one petal, funnel-ſhaped; tube cylindrical, elongated; limb in from four to nine roundiſh, ſpreading ſegments, much ſhorter than the tube. *Stam.* Filaments very ſhort, in the mouth of the corolla, and equal in number to its ſegments; anthers linear, erect. *Piſt.* Germen roundiſh, inferior; ſtyle thread-ſhaped, rather longer than the tube; ſtigma obovate, notched. *Peric.* Drupa dry, roundiſh or ovate. *Nut* of from four to ſix cells, not burſting, with one ſeed in each.—Some flowers have only the rudiments of a germen, and others no ſtamens, in the ſame cyme, which induced Linnæus to refer the genus to *Monoecia*; but ſuch differences, not accompanied by a difference of ſtructure in the other parts, are liable to vary, nor have they been obſerved in more than the firſt ſpecies.

Eſſ. Ch. Calyx ſuperior, cylindrical, ſlightly toothed. Corolla of one petal, funnel-ſhaped. Anthers in the mouth of the tube. Drupa dry. Nut with ſeveral ſeeds.

1. G. *ſpecioſa*. Linn. Sp. Pl. 1408. Olb. It. 275. Lamarck. Dict. v. 3. 53. Illuſtr. t. 154. f. 2. (Rava Pou; Rheede Hort. Mal. v. 4. 99. t. 47, 48. Cadamba jaſminiflora; Sonner. Voy. v. 2. 228. t. 128.)—Leaves roundiſh, acute; heart-ſhaped at the baſe; naked on both ſides. Flowers ſeven or nine-cleft.—Native of Java. Cultivated in various parts of the Eaſt Indies, for the fragrance of its flowers. A tall *tree*, with numerous purpliſh, ſlightly downy branches. *Leaves* oppoſite, on ſhort ſtalks, a ſpan long and nearly as broad, roundiſh or obovate, acute, entire, though a little

a little wavy; ſmooth and naked on both ſides, with one rib and many alternate ſomewhat radiating veins; paler beneath. *Flower-ſtalks* axillary, ſolitary, ſhorter than the leaves, naked, each bearing a cloſe, ſhort, downy cyme. *Flowers* ſeſſile, *Calyx* ſlightly waved rather than toothed. *Tube* of the corolla above an inch long, downy; limb in ſeven, eight, or nine obovate almoſt horizontal ſegments. *Fruit* globoſe, depreſſed, its nut curiouſly lobed and ſinuated, not burſting, containing about ſix ſeeds. The ſynonym of Rheede is very erroneouſly cited by Linnæus for his *Nyctanthes hirſuta*, *Jaſminum hirſutum*, Sm. Exot. Bot. t. 118.

2. G. *argentea*. Lamarck. Dict. v. 3. 54. Illuſtr. t. 154. f. 1. Willd. 399. (Haleſia arboreſcens; Brown. Jam. 205. t. 20. f. 1.)—Leaves roundiſh, acute; heart-ſhaped at the baſe; downy beneath. Flowers five-cleft.—Native of Jamaica; "in ſixteen-mile-walk." *Browne*. A ſmall *tree*, eight or ten feet high; the *ſtem* three or four inches in diameter. It has much the appearance of the preceding, with which Linnæus and even Swartz confounded it; but the *leaves* being downy or ſilky beneath, and the *flowers* with only five, rarely four or ſix, ſegments, and as many ſtamens, ſeems to prove it diſtinct. Lamarck in his deſcription appears to miſtake Browne's definition, "*ſuſtentaculis longis alaribus*," as meaning the ſtipulas, not the flower-ſtalks; he therefore leaves out the word *inſidentibus*, which makes the whole clear in the original, and is miſled to diſtinguiſh this ſpecies from the former by the ſtipulas, which we find exactly alike in both. Browne named this plant *Haleſia*, in honour of Dr. Hales, not knowing that Linnæus had deſtined another genus for this purpoſe.

3. G. *rugoſa*. Swartz. Ind. Occ. v. 1. 632.—"Leaves ovate, acute, rough; ſomewhat heart-ſhaped at the baſe; downy beneath. Flowers ſix-cleft."—Native of Antigua and Dominica.—A *tree*, with alternate, upright, ſubdivided, round, ſcarred branches. *Leaves* ſtalked, moſtly terminal, oblong or ovate, rather coriaceous and rigid, heart-ſhaped at the baſe, entire; rough on the upper ſide, with elevated points; hairy or downy underneath. *Flowers* white, ſilky and ſilvery at the outſide, ſmaller and with a ſhorter tube than the laſt. *Fruit* red. *Swartz*.

4. G. *elliptica*. ibid. 634.—"Leaves elliptical, downy. Flowers four-cleft."—Native of dry fields in Jamaica. A *tree*, 20 feet high, with ſmooth round branches. *Leaves* ſtalked, oppoſite, often ternate on young branches, elliptical, obtuſe, entire, rigid, ribbed, very veiny; ſmoothiſh above; hairy or downy beneath. *Tube* of the flower often an inch long, but the limb very ſmall. *Fruit* with four ſeeds. *Swartz*.

5. G. *membranacea*. ibid. 635.—"Leaves ovate, pointed, membranous, rough, with minute briſtles. Flowers four-cleft."—Native of mountainous thickets in Hiſpaniola. A *ſhrub* or ſmall tree with upright rough branches. *Leaves* ſtalked, oppoſite, ribbed and veiny, the veins briſtly, like thoſe of gooſegrafs, with minute, curved prickles. *Foot-ſtalks* long, flaccid, rather hairy. *Flowers* whitiſh, their tube half an inch long. *Fruit* the ſize of a ſmall pea, containing four ſeeds. *Swartz*.

What Lamarck's figures 3. and 4. repreſent, we have no information, as the letter-preſs to his plates finiſhes at t. 145, nor are theſe plants deſcribed in his dictionary. His *Guettarda coccinea*, Aublet t. 123, is *Iſertia* of Schreber, to which article we refer the reader.

GUEVARA, Antony de, in *Biography*, who flouriſhed in the 16th century, was born in the province of Alava, in Spain; he was brought up at court, but after the death of queen Iſabella of Caſtile, became a Franciſcan monk, and obtained ſome honourable employment in his order. His eloquence cauſed him to be appointed preacher to Charles V., and he acquired much reputation by his pulpit oratory. To Charles he was alſo hiſtoriographer, but his total diſregard to accuracy rendered his labours, in this department of knowledge, of no eſtimation whatever. His delight in fiction accompanied him into the pulpit, and he would, in his ſermons, read, as quotations from ancient authors, paſſages that exiſted only in his own manuſcript. He was nominated to two biſhoprics, and died in 1544. He was author of "The Dial of Princes, or Marcus Aurelius," pretending to be a hiſtory of that emperor and Fauſtina his wife, drawn from ancient authority, but entirely fictitious. It went through many editions in the French and Italian languages as well as in Spaniſh. He wrote "Golden Epiſtles," and ſeveral other works.

Guevara, *Don* Juan Ninno de, a Spaniſh painter of hiſtory and portraits, who was a ſcholar of D. Miguel Manrique, and after him of Cano, at Madrid; whoſe forms and ſtyle of compoſition he adopted, and executed with great force in his chiaro-ſcuro, and boldneſs of touch. In teint he endeavoured to imitate Rubens and Vandyke, and many of his portraits reſemble the works of the latter very much. His principal works are at Seville, Cordova and Malaga. At the latter place he was born in 1632, and died in 1698.

GUEVEI, *Antilope pygmæa*, in *Zoology*, a ſpecies of antelope, with very ſhort, conically pointed, twiſted horns, which are wrinkled at the baſes. It is the Gueve-major of Adanſon and Buffon, and the royal antilope of Pennant. This very elegant little animal, which inhabits Senegal, Guinea, and the hotteſt parts of Africa, is only about nine inches high, and yet is ſo very active, that it is ſaid to leap over a wall 12 feet high. Its colour is reddiſh-brown, with jet-black horns about two inches long, the female having no horns. The ears are broad, and the legs are ſcarcely bigger than gooſe-quills. It is eaſily made very tame and familiar; and it is ſo tender as not to bear being tranſported to Europe.

GUEUGNON, in *Geography*, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the diſtrict of Charolles. The place contains 1257, and the canton 5949 inhabitanes, on a territory of 252½ kiliometres, in 9 communes.

GUEVINA, in *Botany*, a name of whoſe origin or meaning we have no account. Molin. Chil. 198. Juſſ. 424. Brown Tr. of Linn. Soc. v. 10. 165. (Quadria; Gen. Fl. Peruv. et Chil. 16. 33. t. Gærtn. v. 3. t. 220.) Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Brown.

Eſſ. Ch. Petals four, irregularly three of them revolute, one erect. Anthers ſunk in the hollows of their points. Two glands at the baſe of the germen in front. Germen two-ſeeded. Stigma oblique. Drupa with a ſingle ſeeded nut.

1. G. *Avellana*. (Quadria heterophylla; Fl. Peruv. et Chil. v. 1. 63. t. 99. f. b. Nebu ſubrotundo fraxini folio; Feuill. v. 3. 46. t. 33.) Native of mountains in Chili. A ſpecimen gathered by Dombey is in ſir Joſ. Banks's collection. A *tree* about 20 feet high, with a tufted top. *Leaves* alternate, pinnate, of four or five pair of ſtalked, heart-ſhaped, toothed, ſmooth, ſometimes auricled, leaflets. *Flowers* ſmall, in long axillary ſpikes, white, moſt of them abortive; they ſtand in pairs in the ſpike, with a bractea to each pair. *Petals* downy, deciduous. *Fruit* round, or ſomewhat oval, ſlightly fleſhy, yelloviſh, turning black ſoon after gathering, very

very aſtringent. *Nut.* like that of the hazel, but firmer and ſweeter, eaten by the Spaniards, who call it *Avellano*, on account of its reſemblance to the *Corylus Avellana*.

GUEULE, in *Architecture.* See GULA.

GUFFER, in *Ichthyology.* See EEL-*pout*.

GUGLIELMI, PIETRO, in *Biography*, a young Neapolitan opera compoſer, who arrived here in 1768, with his wife from one of the Venetian conſervatorios, as ſecond woman, who had a fine and uncommon counter-tenor voice for a female, and ſung very well.

Guglielmi had at this time ſome Neapolitan fire, and brought over the new and faſhionable muſical phraſes from Italy, but he wrote too faſt, and with little invention or ſelection of paſſages. Indeed he arrived here at an unfortunate period, when cabals in favour of Cocchi, Bach, Vento, and Giardini, as compoſers of ſerious operas, ran high; and when the comic operas of Piccini were ſo juſtly admired, that their merit was not likely to be effaced or eclipſed by a compoſer of inferior fame and intrinſic worth, when it was leſs the intereſt of rival candidates for public favour to decry the productions of Piccini who was abſent, than of Guglielmi who was preſent, and a mark for envy and detraction to ſhoot at. Guglielmi never had great ſucceſs here. Indeed, it ſeems to have been fairly proportioned to the abilities he manifeſted, though he has ſince compoſed much better in Italy, and ſometimes with great ſucceſs. His harpſichord pieces which he compoſed here were full of froth, and common paſſages, and had little other merit than *appearing* difficult, though of eaſy execution; and which, though pert, could never be called dull or tedious.

GUGLIELMINI, DOMENICO, was born at Bologna on the 27th of September, 1655. The great progreſs which he had made in mathematics, was evinced by his publications at the age of 21 years. He was admitted doctor of medicine at the age of 22; and ſoon after he was permitted to teach the mathematics, although he did not obtain the title of profeſſor until the year 1694. In 1696 he was elected a member of the principal learned ſocieties of Europe; and in 1702 the univerſity of Padua offered him the profeſſorſhip of the Theory of Medicine, an office which he accepted and fulfilled with great reputation. He died on the 11th of July, 1710, in the 55th year of his age. His numerous publications were collected, and edited, by Morgagni, under the title of "Opera omnia Mathematica, Hydraulica, Medica, et Phyſica. Acceſſit vita auctoris à J. B. Morgagni," Geneva, 1719, in two volumes 4to. Eloy. Dict.

GUGLINGEN, in *Geography*, a town of Wurtemberg, on the Zaber; 22 miles S.S.E. of Heidelberg. N. lat. 49° 5'. E. long. 9° 7'.

GUGUAN, or ST. PHILIP, one of the Mariane, or Ladrone iſlands. N. lat. 17 50. E. long. 146 20'.

GUHRAU, a town of Sileſia, and principal place of a circle, in the principality of Glogau; 17 miles E. of Gros Glogau.—Alſo, a town of Sileſia, in the principality of Neiſſe; 6 miles S.W. of Grotkau.

GUIRE, a town of Perſia, in the province of Lariſtan; 16 miles E. of Lar.

GUHUNGEKKALA, a town of Aſiatic Turkey, in the province of Adana; 25 miles N. of Adana.

GUIANA, an extenſive territory of South America, bounded on the N. by the provinces of Venezuela and Caraana, or rather by the river Orinoco or Oronoko, on the E. or N. E. by the Atlantic ocean, on the S. by the river Maranon, and on the W. by New Granada. Its extent from E. to W. has been eſtimated at 1100 miles, and its breadth from N. to S. from 300 to 600. Several ſettlements have been formed on the ſea-coaſt by the Dutch, French, and Portugueſe; the latter having been united to the government of the Brazils, and now conſidered as part of that country.

GUIANA, *Dutch*, now (1810) for the moſt part in the poſſeſſion of the Engliſh, was taken poſſeſſion of by the Dutch for the firſt time in 1663, but four years afterwards they were expelled by the Engliſh, whoſe deſcendants form part of the colony, retaken by the Dutch in 1676, and ſince ſubject to a variety of viciſſitudes. Dutch Guiana lies to the N.W. of the French ſettlement, and is bounded on the E. by the river Maravina or Maroni, and on the W. by cape Naſſau: it is often called Surinam, from a river of that name on which the capital is ſituated. Its length from S.E. to N.W. is about 350 Britiſh miles, along the ſhores of the Atlantic, but its breadth is only 60. This colony is divided into four provinces, Surinam, which is the chief ſettlement, Berbice or Berbiz, Demerara, and Eſſequibo or Eſquivo, deriving their names from different rivers. (See each reſpectively.) The chief towns are Paramaribo, New Middleburg, and Demerara. The largeſt river is the Eſquivo; and the Berbiz and Corentin are alſo conſiderable rivers. The wet and dry ſeaſons in this climate, which are ſaid to be equal to thoſe of the Weſt India iſlands, alternate each for three months. The long wet ſeaſon is from April to September. The ſhort from the middle of November till January. From the middle of January to the end of April, the air is dry and clear, and comparatively cool. The natives are of a reddiſh brown or copper colour, like the other American tribes. The Caraibs towards the coaſt are ſavages; who being engaged as auxiliaries to ſuppreſs a negro revolt, devoured the bodies of the ſlain. The cruelties of the Dutch ſettlers, and eſpecially the women towards their ſlaves, ſurpaſs all deſcription; and it appears from Stedman's account, that the phlegmatic character is capable of greater atrocity than any other. Among the vegetable productions of this colony, we may mention the ſilk-cotton tree, which is often twelve feet in circumference, and hollowed into canoes of conſiderable burden; the red mangrove tree, which ſends forth from its branch and trunk an infinite number of filaments, like a ſhip's ropes, which fall into the ground, take root, and riſe again; the palm, deſcribed by Stedman, which ſeems to be the drunken tree of Paraguay. Among the animals are the lauba, which is amphibious and of ſmall ſize, and the tiger, variegated with black longitudinal ſtripes from head to tail; and the ſnake, one of which is deſcribed as being 33 feet long, and three feet in circumference. Towards Patamaca, on the W. of the river Maroni, the mountains reach within 20 miles of the ocean, a branch of the main chain, which proceeds E. and W. and cauſes the rapids in the river Surinam, about 80 miles from its mouth.

GUIANA, *French*, is ſometimes called *Cayenne*, from a town of this name, ſituated on a ſmall iſle or delta, called Cayano. By the peace of 1801, the ſouthern boundary is the river Arawary or Aracary, and a direct line from its ſource to the Rio Blanco. The limit betwixt the French ſettlements and the Portugueſe is more clear and preciſe than that on the N., where an arbitrary and undetermined line, at the diſtance of about 1½ degree, or 100 geographical miles from the former, divides them from the Spaniſh and Dutch poſſeſſions, as far as the river Maroni on the E. The limit paſſing the Maroni at N. lat. 3 15' thence aſcends N. in a line with the river Mana, at the mouth of which was, or is, a French poſt about ten miles from the mouth of the river Maroni, which is in the Dutch poſſeſſions;

though, by other accounts, the Maroni is the boundary, with a Dutch poſt on one ſide, and a French on the other. From the Mana to the Arawary, the French ſhore is of conſiderable extent, being about 6°, or 360 geographical miles. Leſcallier computes the white inhabitants of the whole colony at 900; the mulattoes, or people of colour, may be 4 or 500, and the negroes 9000. Beſides the *Galibis* (which ſee) there are many other Indian tribes, moſtly of middle ſtature, but the women leſs, and not ſo well formed as the men. The Indians generally ſtain their ſkin of a red colour with roucou, or arnotto, a defence againſt the muſquitoes. They reckon time by the revolution of the moon and of the Pleiades. Some of them play on the flute, ſo as to produce a ſound reſembling the bellowing of an ox. Girls often chooſe their huſbands by preſenting drink, the acceptance of which conſtitutes the whole ceremony. To the vegetable and medicinal drugs enumerated under the article Cayenne, we may here add the arnotto (bixa orellana), the quaſſia, quaſſia ſimarouba, the ricinus or caſtor-oil nut, the caſſia fiſtula, the palms, cowhage, balſam of capivi, and the ipecacuanha; the troolies, with very large leaves, with which moſt of the houſes are thatched; the caoutchouc or elaſtic gum, the caruna, which is a ſmall tree, the farinaceous nut of which furniſhes the ſlow poiſon of the Accawau Indians, and the Ticuna poiſon proceeds from the roots of certain climbers called nibbees, which inhabit the entangled foreſts of the immenſe ſwamps of the country. Pinkerton's Geog. vol. iii. For other particulars, ſee CAYENNE.

GUIANA, *Portugueſe*, is a portion of Guiana generally conſidered, whoſe length may be computed from the mouth of the Arawary to the vicinity of the Rio Negro, about 11 degrees, or 660 geographical miles; while the medial breadth, from the mountains of Tumucurang to the Maranon, may be four leagues or 240 geographical miles. The greater part of this extenſive country is occupied by ſavage tribes whoſe names are little known; but the Portugueſe, from their convenient ſtation at Para, on the mouth of the Tocantin river, have opened conſiderable intercourſe with the ſhores of the Maranon, and founded ſeveral ſtations, chiefly miſſionary, as far as the Rio Negro. The little fortreſs of Macapa, on the N. or rather W. of the mouth of the Maranon, was founded by the Portugueſe in 1688, and their right was confirmed, in oppoſition to the pretenſions of the French, by the treaty of Utrecht in the year 1713. On aſcending the courſe of the Maranon, the fortified village of Paru occurs; and at a noted ſtrait of the Maranon is the little fortreſs of Pauxis. Where the Rio Negro joins the Maranon, the Portugueſe have a fortreſs, lat. 3 9', according to Alcedo, who adds that they thence capture Indians for their mines, and that along the Rio Negro there are many miſſions of the Portugueſe Carmelites. The other Portugueſe ſettlements in Guiana are chiefly miſſionary ſtations, which, by the recent account of Depons, approach to the Spaniſh fortreſs of San Carlos, on the Rio Negro. N. lat. 1 53'. So that the preſent eaſtern boundary of Portugueſe Guiana extends to the great river Negro. The equator was the original boundary to the N., but the Portugueſe have extended their poſſeſſions two leagues farther, for there are ſituated the iſle St. Joſeph, and the mountain Gloria del Coeui, regarded as the preſent boundaries. Pinkerton.

GUIANA, *Spaniſh*, called in ſome maps New Cumana or New Andaluſia, a province of South America belonging to the Spaniards, comprehending an extent, according to Depons, of 1020 leagues in circumference. It is bounded on the S.E. by the Dutch and French poſſeſſions, on the S. by the Portugueſe, the line of demarcation paſſing nearly parallel with the lake of Parima, and the great chain of mountains called Tumucarang. The preciſe weſtern boundary is the weſtern mouth of the river Yapura, thence proceeding almoſt due north till it joins the weſtern limit. The boundaries aſſigned by Depons to Spaniſh Guiana are on the E. the Atlantic from the cape of Naſſau to the mouth of the Oronoko, a ſhore of only 30 leagues; on the N. and W. the Oronoko, till it receives the Guaviari, where it is bounded by the Portugueſe poſſeſſions. According to this writer (Travels, vol. ii. p. 353.) Spaniſh Guiana from the mouths of the Oronoko to the limits of the river Portugueſe occupies a ſpace of more than 400 leagues. Its breadth in the firſt 80 leagues to the E. is not more than 30 leagues S, where it is bounded by the poſſeſſions of the Dutch, but then its breadth increaſes to more than 150 leagues. Upon this immenſe ſurface it has but 34,000 inhabitants of all conditions and all colours, of whom 19,425 Indians are under the conduct of the miſſionaries, 6575 in the capital, and the remaining 8000 in the other villages. The greateſt population is from 50 leagues from the ſea to 130 leagues up the Oronoko. Depons divides Guiana into the Upper and Lower Oronoko; the capital being adopted as the point of diviſion But this, however, he ſays, would more juſtly belong to the river Caroni, becauſe it bounds, on all the weſtern part, a territory that might properly be called an iſland; for it has the Oronoko to the N., the ſea to the E., the river Eſſequibo to the S., and the Caroni to the W. It forms almoſt a ſquare of 70 leagues from E. to W., and 30 leagues in its leaſt breadth from N. to S. America has few lands more fertile than thoſe within this circumference. Watered by a number of rivers, which for ages have augmented the bed of mould, they reproach man for his indolence and ſloth. The miſſionaries, notwithſtanding their zeal for making converts, have not yet penetrated more than 30 leagues from the coaſt; the interior parts being occupied by the Caribs, the moſt courageous and ferocious of all the Indians; and as the Dutch of Surinam are intereſted in extending their commerce in Spaniſh Guiana, they encourage the Caribs in their reſiſtance to the progreſs of the Spaniards. Upper Guiana comprehends every thing which is to the E. of the river Caroni, commencing a league above St. Thomas, and which depends on the miſſion of the Franciſcans. Such is the indolence of the inhabitants, that upon the moſt productive land in the world, few plantations are ſeen, which are badly cultivated; theſe are ſituated at 30 leagues to the S. of the capital of Guiana, on which the proprietors raiſe a little cotton and ſugar, and ſome country proviſions. The ſoil is excellent, eſpecially for tobacco. The moſt remarkable feature of Spaniſh Guiana is the courſe of the river *Oronoko*, for an account of which ſee that article. For an account of the capital, ſee SAN THOMAS. Depons, in forming a judgment of the riches or poverty of Guiana, eſtimates what the tithes produce. In 1803 the tithes of all Guiana ſold for 4000 hard dollars a year. Suppoſing that the farmer gained 50 per cent. and carry it to 6000, that would give an annual revenue of 60,000 hard dollars for every thing generally conſumed in Guiana, or exported from it. But in calculating the tithes, the products of the herds of the Capuchin miſſionaries are not allowed in the account, becauſe they are exempt. The horned beaſts which they poſſeſs are eſtimated at 150,000, which of courſe make a part of the riches of Guiana There were, notwithſtanding, exported through the port of Guiana, from 1791 to 1794, in articles from this province, and alſo from that of Varinas, 10,380 oxen and 3140 mules; and they in return introduced 200 blacks, and 349,448 hard dollars,

dollars in ſpecie. From 1791 to 1795 they exported for Europe in ſilver 25,203 hard dollars, and in goods 363,397 hard dollars. At this day the commerce is reduced to leſs than one-half. At the end of 1803 there were in Guiana 34 ſmall veſſels employed in the coaſting trade in the colonies, and the trade was then in the hands of a few Catalonians.

GUIANA-*Bark*, in the *Materia Medica*, the ſame with what is otherwiſe called *Sima-rouba*.

GUIB, ANTILOPE *ſcripta*, Harneſſed antilope of Pennant, in *Zoology*, is a ſpecies of antelope with horns ſtraight, tapering, ſharp-pointed, and directed backwards, having two ſpiral edges along their whole length. The body is marked with two longitudinal white bands along the ſides, which are croſſed by others in a perpendicular direction, having the appearance of harneſs. Its habitat is Africa, living in large herds in the plains and woods. The horns are nine inches long, the ears broad. The general colour cheſnut; beneath each eye is a white ſpot, and on the thighs are white ſpots; the under part of the neck, a part of the cheeks, and the inner parts of the legs are white; the forehead and ridge of the back are black. It is 4½ feet long from the noſe to the rump, and two feet eight inches high; the tail is 10 inches long, and is covered with long hairs. It is called by the negroes Ouloſes, or Jaloſes.

GUIBARA, in *Geography*, a town of the iſland of Cuba; 163 miles N. of St. Jago.

GUIBARRA, a river of Ireland, in the county of Donegal, which is of extraordinary breadth and depth for the ſhortneſs of its courſe. It falls into the Atlantic ocean ſome miles to the ſouth of the iſles of Arran.

GUIBERT, in *Biography*, a native of Parma, was chancellor to Henry IV. king of Germany; and, through his favour, he was advanced to the archbiſhopric of Ravenna. He was a man of turbulent paſſions, and is ſuppoſed to have been the projector of Cincius' inſurrection againſt Gregory VII. hoping, in caſe of his death or depoſition, to be appointed to ſucceed him. He at length attained his wiſhed-for object, and was, in 1084, conſecrated in the church of St. Peter, when he took the name of Clement the Third. In the following year a ſentence of excommunication was thundered out againſt him, in the council aſſembled by Gregory's legate at Quintileneberg, in Saxony. In the ſame year a council, held at Mentz, anathematized the prelates who had met at Quinteleneberg; and all perſons were forbidden, on pain of excommunication, to communicate with them, or their aſſociates. In 1087, upon the election of Victor III. Guibert was driven from Rome by the forces with which the princes of Capua and Salerno ſupported that pontiff's pretenſions, notwithſtanding which event he was ſoon re-eſtabliſhed in the poſſeſſion of that city. He was afterwards excommunicated and curſed anew by Victor, who preſided in perſon at the council of Benevento. During the pontificate of Urban II. Guibert was ſometimes maſter of Rome, and ſometimes a fugitive from that city, as the imperial or oppoſite party prevailed. He was at length finally expelled the city, and then driven from his biſhopric of Ravenna by pope Paſchal II. He retired to the mountains of Abruzzo, where he died ſuddenly in 1110, having made his claim to the papal character for the ſpace of 20 years. He was a man of great learning, eloquence and addreſs.

GUIBERT, Abbot, an hiſtorian, was born in the dioceſe of Beauvais in the year 1053. He was brought up in the monaſtery of St. Germer, and was, in 1104, elected abbot of Nogent-Sous-Couxi, in the dioceſe of Laon, where he died in 1124. His works conſiſt of his life, a treatiſe on preaching, and another on reliques; but his moſt valuable piece is the hiſtory of the firſt cruſade, commonly entitled "Geſta Dei per Francos."

GUIBERT, JACQUES-ANTOINE-HYPOLITE, born at Montauban in 1743, was ſon of an officer of rank and merit, and ſerved, with his father, in many campaigns, in which he greatly diſtinguiſhed himſelf, and at length was appointed colonel-commandant of a corps, raiſed under the title of the Corſican Legion. In 1770 he publiſhed his principal work, entitled, "Eſſai Général de Tactique." This work was read with great applauſe by all perſons, who underſtood the ſubject, in Europe. In 1773 he made a tour in Germany and Hungary as far as Croatia, viſited the principal fields of battle, and collected details of every kind relative to military ſubjects. On his return to France he made an eſſay in dramatic hiſtory; and ſome of his pieces were repreſented with much applauſe. He undertook a "Hiſtory of the French Military," which was, in fact, to embrace the military ſyſtem of all the nations of Europe. He carried it as far as the eleventh century, but it has not been publiſhed. He was author of many other works. He died in May, 1790, leaving behind him a widow and one daughter. The regiment of Neuſtria, which he had commanded 10 years, gave a handſome teſtimony of their eſteem and regret for the deceaſed in a letter to his widow.

GUICCIARDINI, FRANCIS, was born at Florence in 1482. After purſuing his ſtudies at Piſa and Bologna, he, at the age of twenty-three, read lectures upon the inſtitutes at Florence. After this he went embaſſador from the Florentine republic to Ferdinand, king of Arragon. By Leo X. the government of Modena and Reggio was committed to his care; and, in 1521, he was made governor of Parma, which city, as well as Reggio, he ſucceſsfully defended againſt the French. He received many other marks of favour and diſtinction from ſucceſſive popes. In 1523 Clement VII. conferred upon him the preſidency of all Romagna, and afterwards nominated him lieutenant-general of the papal army; but he was not ſufficiently ſkilful, or ſufficiently powerful to protect his ſovereign from the imperial arms. From 1531 to 1534 he was governor of Bologna, and exerted himſelf conſiderably to reſtore the Medici family in Florence. After the death of Clement he returned to his native city, where he was made counſellor of ſtate to duke Alexander. Upon the death of this prince, Guicciardini employed his influence in procuring the ſucceſſion of Coſmo; but not thinking himſelf ſufficiently conſidered by the new duke, he retired to literary occupation. His great work, which is known in ſeveral modern languages, *viz.* the "Hiſtory of Italy, during his own time," did not appear till many years after his death, on account, probably, of the freedom of ſome of its ſtrictures on many living characters. The hiſtory of Guicciardini is allowed to be one of the moſt valuable productions of the kind in that age. He had a good opportunity of knowing the facts concerning which he wrote; and his impartiality and veracity are very conſpicuous. His ſtyle is pure and eloquent, but ſometimes too diffuſe. Perhaps, however, it is the ſmallneſs of the events which his ſubject led him to deſcribe, that chiefly renders the narration tedious. The defects are, after all, very trifling compared with the excellencies, and they do not, by any means, prevent its being a ſtandard work, and a great honour to Italian literature.

GUICCIARDINI, LEWIS, nephew of the preceding, was born at Florence in 1521, and was educated with a view to literary leiſure. About the year 1550 he took up his reſidence in the Low Countries, where he continued till his death in 1589. He was author of many works, of which

the principal is "A Deſcription of the Low Countries," which is in great eſteem for the accuracy of its relations. His other works are "Commentaries on the Affairs of Europe, particularly in the Low Countries, from 1529 to 1560." "Remarkable words and actions of Princes," &c. "Hours of Amuſement;" and a collection of the precepts and maxims of his illuſtrious relation. He was buried in the cathedral of Antwerp, where an honourable inſcription is placed to his memory.

We ſhould not have thought him entitled to notice, as a muſical writer, except to diſpute his opinion concerning the invention of counter-point.

In travelling through the Netherlands, in 1772, in ſearch of materials for a "General Hiſtory of Muſic," we did not quit Ghent without viſiting the principal libraries there, in hopes of meeting with ancient manuſcript muſic, which might aſcertain the aſſertion of Lodovico Guicciardini, that counter-point took its riſe, and was firſt cultivated in Flanders; but we neither found at the abbey of St. Peter (the oldeſt and richeſt in Flanders) nor at the Auguſtines, or Dominicans, where the libraries are very conſiderable, any thing to our purpoſe.

But at Antwerp we fully expected to meet with materials the moſt important to the hiſtory of counter-point, or muſic in different parts, as it was here, according to Lodovico Guicciardini, and, after him, ſeveral others, who took the fact upon truſt, that moſt of the great Flemiſh muſicians, who ſwarmed all over Europe in the 16th century, were bred.

The Abbé du Bos (Reflex. t. 1. ſect. 451.) after his eloge of Lulli (p. 45.) whom he calls "the greateſt poet-muſician of whoſe works we have any knowledge," aſſerts roundly that "muſic had its birth in Flanders;" and, in confirmation of this aſſertion, quotes Lodovico Guicciardini's Deſcription of the Low Countries, as an indiſputable voucher, in ſupport of the fact.

Guicciardini, indeed, gives a liſt of more than 20 eminent Flemiſh muſicians and Netherlanders, who flouriſhed at the end of the 15th, and during the 16th century, who were diſperſed in all the courts of Europe; but, unluckily, at the head of theſe he places John Tinctor de Nivelle, five leagues from Bruſſels, who, ſo far from arrogating to himſelf, or his countrymen, the invention of counter-point, or muſic in parts, gives it to an Engliſhman. Speaking of counter-point, he ſays: "Cujus ut ita dicam novæ artis fons et origo, apud Anglos, quorum caput Dunſtable exiſtit fuiſſe perhibetur." The title of Tinctor's tract, which we never ſaw, except in Padre Martini's collection, is the following: "Tract. mulices Explanat. manus, de Tenor. natura et proprie. de notis et pausis de regul. valore, imperfect. et alterat. notar. de arte contrap."

The teſtimonies of Franchinus and Tinctor are very reſpectable, and do us great honour; yet we cannot conſcientiouſly, from conviction, ever accept of the gift. That the Netherlands produced excellent muſicians in the 15th and 16th centuries, cannot be denied; but that experiments in harmony were making, not only in England, but in every civilized part of Europe, long before the time of our countryman, Dunſtable, is equally certain. See Franco, Jos. Cottos, Hubald, Odo, Marchetto, and Odington.

To confeſs the truth, we have always regarded the teſtimony of L. Guicciardini and the Abbé du Bos, with reſpect to this point of muſical hiſtory, as equally ſuſpicious. Lodovico Guicciardini, who was a renegade Italian, ſettled at Antwerp, in the ſervice of the emperor Charles V. ſeems, in his hiſtory of the Low Countries, determined to give the people among whom he lived the honour of every uſeful as well as ornamental invention, in order to flatter his patron and benefactors, even at the expence of his native country, from which he had no farther hopes. The Abbé du Bos, from a contrary principle, wiſhed to give the honour to the Flemings, in order to pilfer it from them afterwards in favour of his own country, France.

GUICHE, La, in *Geography*, a town of France, in the department of the Saone and Loire, and the chief place of a canton, in the diſtrict of Charolles; nine miles N. N. E. of Charolles. The place contains 1047, and the canton 6355 inhabitants, on a territory of 217½ kiliometres, in twelve communes.

GUICHEN, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the diſtrict of Rédon. The place contains 2660, and the canton 11,820 inhabitants, on a territory of 262½ kiliometres, in eight communes.

GUIDA, *Ital.* as *Dux*, in Latin, implies, in *Muſic*, the part in fugues and canons which leads off, or begins the ſubject, and which the *conſeguenza*, or part which comes in ſecond, is to anſwer. See Proposta, Antecedente, Presa, and Soggetto.

GUIDAGE, Guidagium, in *Ancient Law Writers*, money paid for ſafe conduct through unknown ways, or a ſtrange country.

GUIDES, in *Military Language*, are uſually the country people in the neighbourhood of an encampment; who give the army intelligence concerning the country, the roads by which they are to march, and the probable route of the enemy.

GUIDI, Alexander, in *Biography*, an Italian poet, was born at Pavia in 1650. At an early age he went to the court of Rannucio II. duke of Parma, by whom he was much favoured and eſteemed. He was firſt known as a poet, by the publication of ſome lyric poems, and a drama, entitled "Amalaſunta in Italia." He afterwards viſited Rome, and frequented the court of the abdicated queen Chriſtina, who employed him to compoſe a piece of muſic to celebrate the acceſſion of James II. of England. He endeavoured to reform the Italian poetry, but his example was but little followed. His poems are ſpirited and vigorous, and he is thought to have happily tranſfuſed into the Italian language the fire and vehemence of Pindar. He attempted a verſion of the Pſalms, but was interrupted in the employment by a call from prince Eugene, governor of Lombardy, to aſſiſt in a plan for diminiſhing the public burthens. For this he was enrolled in the number of Parma patricians. He now returned to Rome to complete a metrical verſion of the homilies of Clement XI. As he was travelling to preſent the pope with a copy of the work, he diſcovered an error of the preſs, which chagrined him ſo much, that it was ſuppoſed to be the cauſe of a fit of apoplexy, that carried him off at Frescati, in June 1712.

GUIDICCIONI, John, was born at Lucca in 1550. Having received an excellent education, he was introduced to the ſervice of cardinal Alexander Farneſe, afterwards pope Paul III. He became very intimate with Annibal Caro, and with many other men of letters at Rome. When his patron was elevated to the popedom, he was made governor of the city, and biſhop of Fossombrone. In 1535 he was ſent nuncio to the emperor Charles V. whom he accompanied in his expedition to Tunis, and on other journeys. He was, about the year 1539, made preſident of Romagna, and afterwards commiſſary-general of the pontifical army, and governor of the Marche. So well did he act his part in all theſe employments, and ſo much dexterity and judgment did he diſplay in all difficult caſes, that he would

would probably have been raiſed to the dignity of cardinal had he not been carried off by a diſeaſe in 1541. He was author of an oration to the republic of Lucca, of many letters, and of a number of poems which gave him a high reputation. His works have been ſeveral times printed. He ſucceeded beſt in grave ſubjects, and particularly in lamenting the calamities to which Italy was at that time expoſed.

GUIDO ARETINO, or GUIDO D'AREZZO, a monk of the order of Saint Benedict, who flouriſhed in the eleventh century, and diſtinguiſhed himſelf by framing a new method of teaching boys to ſing, and laying the foundation of the preſent ſyſtem of muſic. Few particulars concerning the life of this ingenious monk would have been known, if, luckily for his fame, he had not himſelf recorded perhaps the moſt important and honourable events of his life, in a letter to his friend Michael, a monk of Pompoſo, which cardinal Baronius has inſerted in his Eccleſiaſtical Annals, vol. xi. p. 74, and introduced it with an account of his having invented "a new method of teaching muſic, by which a boy might make a greater progreſs in a few months, than a man of intelligence and aſſiduity uſed to do in ſeveral years." This author likewiſe informs us that the ſingular ſervice which Guido had rendered muſic, having been communicated to pope Benedict VIII. that pontiff ſent for him to Rome, and treated him with great kindneſs: a circumſtance which happened, according to Baronius, in the year 1022.

It ſeems, however, as if Guido had not been ſo far dazzled by the ſplendour of a court, or the honours he had received at Rome, as to remain long in that city; for Benedict dying in 1024, we find by his own letter to the monk Michael, that his ſucceſſor, John XX. or, as ſome ſay, the XIXth. had ſent three meſſengers to invite him to return to Rome. On his arrival there a ſecond time, his reception from the new pontiff was ſtill more flattering than from his predeceſſor. He frequently condeſcended to converſe with him freely on the ſubject of his muſical diſcoveries; and when Guido firſt ſhewed him his Antiphonarium, or notation of the maſs for the whole year, his holineſs regarding it as a prodigy, would not quit his ſeat till he had learned to ſing a chant in it by Guido's new method, and had by this means accompliſhed that himſelf which he hardly believed poſſible when it was reported to have been done by others.

The pope, deſirous to retain him in his ſervice, preſſed him to continue at Rome; but Guido, finding himſelf unable, from the bad ſtate of his health, to bear the approaching heat and bad air of that city during ſummer, left it, upon a promiſe of returning thither in winter, to explain his new ſyſtem in a more ample manner to his holineſs.

When he quitted Rome he made a viſit to the abbot of Pompoſo, a town in the duchy of Ferrara, who ſo ſtrongly ſolicited him to ſettle him in his convent, that at length he conſented, in hopes, as he ſays, "of extending the fame of that great monaſtery by his future labours."

Guido Aretinus has been miſtaken by Merſennus, Voſſius, and others, for Guitmond, monk of St. Lufrid, in the dioceſe of Evreux in Normandy, afterwards biſhop of Averſa, who wrote againſt the hereſies of Berenger; he has been confounded by ſome Italians, likewiſe, with Guitton d'Arezzo, the poet, and one of the founders of the Italian language, who flouriſhed about the time of Dante, by whom he is celebrated, as well as by Petrarca, Redi, and almoſt all the poets of Italy.

Few perſons who ſpeak or write on the ſubject of the preſent ſyſtem of muſic expreſs the leaſt doubt of counterpoint having been invented by Guido, a monk of Arezzo, in Tuſcany, about the year 1022. But there is nothing more difficult than to fix ſuch an invention as this upon any individual; an art utterly incapable of being brought to any degree of perfection, but by a ſlow and gradual improvement, and the ſucceſſive efforts of ingenious men during ſeveral centuries, muſt have been trivial and inconſiderable in its infancy; and the firſt attempt at its uſe neceſſarily circumſcribed aud clumſy.

Guido, however, is one of thoſe favoured names to which the liberality of poſterity ſets no bounds. He has long been regarded in the empire of muſic as *lord of the manor*, to whom all ſtrays revert, not indeed as chattels to which he is known to have an inherent right and natural title, but ſuch as accident has put into the power of his benefactors; and when once mankind have acquired a habit of generoſity, unlimited by envy and rival claims, they wait not till the plate or charity-box is held out to them, but give freely and unſolicited whatever they find without trouble, and can relinquiſh without loſs or effort.

But, in order to aſcertain with ſome degree of method and accuracy how much modern muſic has been indebted to this celebrated monk, it ſeems neceſſary to give a liſt and analyſis of the writings that have been attributed to him. The tract which is moſt frequently mentioned, and, except by the few that have ſeen it, is ſuppoſed to contain all the inventions with which Guido has been inveſted, is the Micrologus. Of this work there are three copies among the MSS. in the king of France's library at Paris; the moſt ancient account of which, No. 7211, is of the twelfth century; and of this we obtained a tranſcript, which was collated with the other two. It is a ſhort treatiſe in monkiſh Latin, and full of obſcurities, containing an account of the author's method of teaching boys to ſing, with rules for the proper performance and compoſition of the plain chant.

Though it is natural to expect to find in this treatiſe an account of the inventions and improvements commonly attributed to him; yet it is vain to ſeek them. He does not *expreſsly claim* any of the inventions; and his expreſſions are ambiguous, even where he ſeems to ſpeak as an inventor; it is always—*nos* ponimus—*noſtris* notis—*noſtram* diſciplinam. Sometimes this ſeems to be only the dignified egoiſm of an author, and ſometimes it ſeems literal. One of the additions to the ſcale of the ancients, he ſeems, however, clearly to diſclaim. The account is that he added the Greek gamma at the bottom of the ſcale; but in this treatiſe his account of the notes begins thus: "In primis ponitur Γ Græcum *à modernis adjectum*."

Another expreſſion ſeems to imply that the diſtinction of B flat and B natural was not of his invention; for he ſays, "b vero rotundum—adjunctum vel molle *dicunt*; *they* call. Yet, in his ſecond chapter, where he gives the notes, he ſeems to ſpeak as if this invention was his own: between a and ♭, ſays he, we put another b, which we make round; but the firſt we make ſquare, thus a. b ♭. c. &c."

His invention of the hexachords muſt have been poſterior to this treatiſe; for, when he gives the ſcale he never mentions them; nor is the term once uſed in the whole manuſcript.

His ſcale is always mentioned as going up to e e; but in the Micrologus he only gives it up to d d. The other note we ſuppoſe was added afterwards, when his ſcale was arranged into hexachords. See SCALE, GAMMUT, and HEXACHORDS.

He ſeems, by his manner of expreſſing himſelf, to claim the honour of having added the *tetrachord ſuperacutarum* as he calls it; for he ſays, "*addimus*, hic eidem literis, ſed variis

into exertion by his need to maintain the waſte of an inſatiable appetite for gaming, has ſtocked the world plentifully with them. Madonnas, Cleopatras, Lucretias, &c. &c. which flowed with eaſe and intereſt from his pencil, are to be met with in every collection. He alſo produced many very large works of aſtoniſhing power; in the executive part particularly. His Aurora leading Apollo mounted in his chariot, and ſurrounded by the hours; the altar piece at St. Philip Neri, at Fano; his penitence of St. Peter, in the Zampieri palace; and many others atteſt the juſtice of that eſtimation in which the talents of Guido have always been, and ſtill continue to be held. He died in 1642, at the age of 68.

GUIDON, Fr. a ſmall ſign, equivalent, in *Muſic*, to *Moſtra*, Ital. and index or *direct*, in Engliſh, its form is this ☞, and its uſe to indicate the ſound which begins the next line. And if this note or ſound is accidentally ſharp, flat, or natural, the guidon, or direct, muſt likewiſe be accompanied by the ſame accident. See INDEX and MOSTRA.

GUIDON, in *Heraldry*, is a ſemi-circular banner, uſed at funerals, on which are painted the creſt and motto of the deceaſed, with ornaments. This trophy cannot properly be carried in any funeral proceſſion except that of a field officer.

GUIDON is alſo a name given to a ſmall banner with the arms of Ulſter painted upon it, uſed only at the funeral of a baronet.

GUIDON, in *Military Language*, a ſort of flag, or ſtandard, borne by the king's life-guard; being broad at one extreme, and almoſt pointed at the other, and ſlit, or divided, into two.

GUIDON alſo denotes the officer who bears the guidon. The guidon is that in the horſe-guards, which the enſign is in the foot. The guidon of a troop of horſe takes place next below the cornet.

GUIDONS, *Guidones*, or *ſchola guidonum*, was a company of prieſts eſtabliſhed by Charlemagne, at Rome, to conduct and guide pilgrims to Jeruſalem, to viſit the holy places: they were alſo to aſſiſt them in caſe they fell ſick, and to perform the laſt offices to them in caſe they died.

GUIDONIA, in *Botany*, was named by Plumier, Nov. Gen. 4. t. 24, in honour of Guido Creſcentius Fagon, phyſician to Louis XIV., to whom Linnæus dedicated another genus under his ſurname. See FAGONIA.

The *Guidonia* of Plumier is therefore the *Samyda* of Jacquin and Linnæus, but his ſuppoſed ſpecies include the *Guarea* of the latter. See GUAREA and SAMYDA.

GUIDONIS GLANDULA. See GLANDULA.

GUIDORE, in *Geography*, a river of Ireland, in the county of Donegal, which flows into the Atlantic ocean, to the north of the iſles of Arran. It is of ſhort courſe, but wide at its mouth.

GUIDOTT, THOMAS, in *Biography*, a phyſician, was born at Lymington, in Hampſhire, in 1638, but his family were originally from Florence. He ſtudied medicine at Oxford, and, after having taken his bachelor's degree, he went to Bath, where he practiſed with conſiderable ſucceſs. In 1679 he came to London. It would appear that he was a man of merit and reputation, as he was invited, in 1684, to teach anatomy at Copenhagen, and in 1690, a profeſſor's chair in medicine was preſented to him at Venice, and another at Leyden. But it is not known whether he accepted either of theſe offers; for his biographers confine themſelves to the mention of his writings relative to the mineral waters of England. Theſe were written both in Latin and Engliſh, with various titles, as "On Natural Baths and Mineral Waters," Lond. 1673. "De Thermis Britannicis," 1691, &c. He alſo publiſhed ſome tranſlations, among which is the book of Theophilus "de Urinis." Eloy.

GUIENNE, in *Geography*, a diſtrict of France, being part of a government under this appellation before the revolution. It lies northward of Gaſcogne, between 44° and 45° 40′ N. lat. being 36 leagues N. to S. and 72° from W. to E. It was ſubdivided into ſix parts, *viz.* on the W. Bourdelois, on the N. Perigord, on the E. Rovergne, on the S. Bazadois, in the centre Agenois and Quercy. The ſoil of Bourdelois, the moſt conſiderable diviſion, is partly light and ſandy, and partly fertile. Its principal products are cheſnuts, figs, and wine. The appellation Guienne is derived, by corruption, from Aquitania, itſelf derived from the abundance of its rivers and ſprings of water.

GUIERA, in *Botany*, "the *Guier* of Senegal." No other account is given of the origin of the name. Juſſ. 320. Lamarck. Illuſtr. t. 360.—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, bell-ſhaped, with five equal upright teeth. *Cor.* Petals five, erect, equal, lanceolate, inſerted into the calyx, much exceeding its teeth. *Stam.* Filaments ten, thread-ſhaped, larger than the petals, five rather ſhorter than the reſt; anthers incumbent, roundiſh, two-lobed. *Piſt.* Germen inferior, longiſh, five-angled, ſlightly hairy; ſtyle thread-ſhaped, nearly equal to the ſtamens; ſtigma capitate, notched. *Peric.* Capſule extremely long, narrow, five-angled, exceſſively hairy, crowned with the calyx, of one-cell. *Seeds*, about five, minute, each hanging by a thread.

Eſſ. Ch. Calyx five-cleft, ſuperior. Petals five. Capſule very long, five-ſided, hairy, of one cell. Seeds five, hanging by a thread.

1. G. *glandulosa*. Native of Senegal, from whence it was brought to M. de Juſſieu, who favoured us with a ſpecimen, by M. Rouſſillon, a ſurgeon, in 1790. Adanſon had found it there, and pointed out ſome of the characters to Juſſieu, but no mention is made of this ſingular plant in his own works. The *ſtem* is ſhrubby or arborſcent, with oppoſite round branches. *Leaves* on ſhort thick downy ſtalks, oppoſite, about an inch long, broadly elliptical, obtuſe with a ſmall point, entire, with one rib, and many parallel veins connected by fine reticulations; both ſides very finely downy or hoary, eſpecially the under one. *Stipules* none. The *flowering branches* are lateral, oppoſite, ſhort, bearing a few much ſmaller, more obovate, and more downy leaves. *Flowers* yellowiſh, in ſhort, denſe, capitate, terminal ſpikes. *Involucres* four under each ſpike, not half an inch long, ovate, acute, entire, reflexed, deciduous. The outſide of the calyx, and under ſide of the leaves and bracteas, are beſprinkled with dark glandular dots, as in *Hypericum perforatum*. The habit and leaves of this ſhrub convey an idea of a ſimple-leaved *Hedyſarum*, while the inflorescence and flowers look like a *Mimoſa*. The *fruit* is altogether peculiar, being about two inches long, crowned with the permanent flower, and denſely clothed with innumerable ſoft ſilky hairs of a tawny or ruſty hue, at leaſt after long keeping. Theſe have ſcarcely any exiſtence in the infant germen. We cannot conceive any reaſon for removing this genus to the *Myrti*, to which Juſſieu ſuſpects it may be more akin than to his *Onagræ*, where he has placed it. There are many points of affinity between it and *Epilobium*.

GUJERJINLIK, in *Geography*, a town of Perſia, in the province of Adirbeitzan; 25 miles N.N.W. of Urmia.

GUIFFA, in *Ornithology*. See LOXIA *Tridactyla*.

GUIFONI, in *Geography*, a town of the iſland of Corſica; 13 miles S. of Corte.

GUIGNAN, an iſland in the Eaſt Indian ocean, near the E. coaſt of the iſland of Samar, about 20 miles in circumference. N. lat. 11° 21'. E. long. 125° 56'.

GUIGNETTE, in *Ornithology*. See TRINGA *Hypoleucos*.

GUIGNON, JOHN PETER, in *Biography*, an eminent muſician, born at Turin 1702, and who eſtabliſhed himſelf early in France, where he began to exerciſe his profeſſion on the violoncello; but he ſoon quitted that inſtrument to devote himſelf wholly to the violin, and became ſuperior to all the maſters who had preceded him. He acquired ſo great a reputation, that, in 1733, he was received into the king's chapel and chamber bands, and appointed muſic-maſter to the dauphin and madame Adelaide. In 1741, he was inveſted with the office of *roi des violons*, king of the violins, a title afterwards lowered to that of *king of the minſtrels*. Of this ſovereignty, both in England and France, we ſhall endeavour to trace the origin, progreſs, and abolition elſewhere. See *king of the* MINSTRELS.

In 1773, Guignon, finding his ſubjects turbulent and factious, he reſigns his crown, and leſt future fidlers ſhould be equally troubleſome to future ſovereigns, obtained the total abolition of its power and dignity.

This *ci-devant* monarch, and celebrated artiſt, died at Verſailles, in 1774, of a paralytic ſtroke. He had retired, in 1762, from all public exerciſe of his profeſſion.

No performer (ſays M. Laborde) had a greater bow-hand, or drew a better tone from his inſtrument.

His houſe was always a gratuitous ſchool for all young people who wiſhed to learn the violin, and many of his pupils have become eminent muſicians.

Guignon was the firſt who formed favourite airs into duets for two performers on the violin, a *parti equali*.

Theſe new kinds of *double ſolos* were executed at the Concert Spirituel by the author and Mondonville, who perfectly underſtood and ſupported each other. No compoſition or performance was ever better received by the public, than theſe admirable *duets*, which have been ſince often imitated, but rarely in ſo charming a manner. Eſſai ſur la Muſique, tom. iii.

GUILANDINA, in *Botany*, ſo named by Linnæus, in memory of Melchoir Guilandinus, a Pruſſian, whoſe real name Haller preſumes was Wieland, and who after ſeveral extenſive journeys into Paleſtine, Egypt, Africa, and Greece, was carried priſoner into Barbary; but being redeemed by the celebrated Fallopius, afterwards ſucceeded him in the botanical chair at Padua, and died in 1587 or 1589. Haller characterizes him as a learned but deſultory writer, an acrimonious critic, even of the excellent Conrad Geſner, but eſpecially of Matthiolus, whom he violently hated. He had little or no merit as a practical botaniſt, nor did he ſcarcely attempt to deſcribe or define any plants. He publiſhed a learned eſſay on the *Papyrus*, in quarto, at Venice in 1572, and various controverſial epiſtles. His *Synonyma Plantarum*, one of the earlieſt works of its kind, appeared long after his death, in 1608, at Frankfort, in octavo.—Linn. Gen. 207. Schreb. 279. Willd. Sp. Pl. v. 2. 534. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 55. Juſſ. 350. Lamarck. Illuſtr. t. 336. Gærtn. t. 148. (Bonduc; Plum. Nov. Gen. 24. t. 39.)—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior; tube ſhort, turbinate, permanent, oblique at the orifice; limb in five deep, nearly equal, ſpreading, oblong, rounded, obtuſe, deciduous ſegments, the two uppermoſt a little the ſhorteſt, and the lower one rather longeſt. *Cor.* Petals five, inſerted into the neck of the calyx; the uppermoſt roundiſh, concave, aſcending, rather the ſhorteſt; the reſt oblong, broadeſt in their forepart, rounded at the extremity, ſpreading and rather reflexed, longer than the calyx, the two loweſt a little longer than the two middle ones. *Stam.* Filaments ten, awl-ſhaped, thicker and moſt hairy at their baſe, decumbent, inſerted into the neck of the calyx, ſhorter than the corolla, unequal, the lower ones being gradually longer than the upper; anthers incumbent, oblong. *Piſt.* Germen ſuperior, oblong, ſomewhat ſtalked; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma ſimple, obtuſe. *Peric.* Legume rhomboid, compreſſed, ſlightly tumid, of one cell and two valves, its upper future convex. *Seeds* few, globoſe, ſlightly compreſſed, very hard.

Eſſ. Ch. Calyx of one leaf, ſalver-ſhaped. Petals five, inſerted into its neck, nearly equal. Legume of two valves and one cell. Seeds few, ſtony.

Obſ. Schreber, who has properly followed Lamarck and others in ſeparating from the Linnæan *Guilandina G. dioica* and *G. Moringa*, (ſee GYMNOCLADUS and HYPERANTHERA,) obſerves that he has ſeen only male flowers of the *Bonduc* and *Bonducella*, and therefore ſuppoſes they are either dioecious or polygamous. Our ſpecimens have ſtamens and piſtil in the ſame flowers.

1. G *Bonduc*. Linn. Sp. Pl. 545. (Frutex globulorum; Rumph. Amb. v. 5. 89. t. 48.)—Prickly. Leaflets ſcattered, ovate, acute; the prickles on their ſtalks ſolitary.—Native of the Eaſt and Weſt Indies, where the Engliſh call it Nicker-tree. It has long ſince been raiſed in our ſtoves, but does not arrive at ſufficient perfection to bloſſom. Rumphius deſcribes it as a very prickly, trailing, and widely-ſpreading *ſhrub*, rather than a tree, entangling itſelf with all around it, but not riſing to any great height. The *leaves* are doubly and abruptly pinnate, their ſtalks variouſly twiſted or curved, beſet underneath with ſcattered ſolitary hooked prickles; the leaflets, according to Rumphius, of four or five fingers' breadth long and two broad, (it muſt always be recollected that his figures are diminiſhed,) on ſhort little ſtalks, ovate, acute, entire, ſmooth. *Flowers* in long, terminal, taper, denſe ſpikes or cluſters, of a tawny yellow, with a long, reflexed, awl-ſhaped, downy bractea under each of their partial ſtalks. *Legumes* three or four inches long, prickly, containing two, three or four ſeeds, which are very hard, grey and ſhining, like boys' marbles, and marked with horizontal ſtreaks. Theſe ſeeds are often kept in cabinets among ſhells, &c. and are ſaid to cauſe coſtiveneſs. The natives of Amboyna devour about 40 of them for ſeveral ſucceſſive days, to render themſelves invulnerable when going to war.

2. G. *Bonducella*. Linn. Sp. Pl. 545. (Globuli majores; Rumph. Amb. v. 5. 92. t. 49. f. 1. Caretti; Rheede Hort. Mal. v. 2. 35. t. 22. Bonduch, Pianta indiana; Zann. Iſt. 44. t. 17. Acacia glorioſa, lentiſci folio, &c.; Pluk. Phyt. t. 2. f. 2.)—Prickly. Leaflets oppoſite, elliptical, acute; the prickles on their ſtalks in pairs.—Native of both Indies, from whence its ſeeds were brought very early to Europe, and raiſed in hot-beds, but the plants have not long thriven. This differs from the preceding in having much ſmaller and more elliptical *leaflets*, regularly two-ranked and oppoſite, with a pair of prickles at the baſe of their partial ſtalks. The *ſeeds* are but two in each legume, otherwiſe there is no great difference. By Rumphius's account this and the former ſeem to be imperfectly dioecious. *G. Bonducella* is the moſt known of the two, though often miſtaken for the former, and is what Lamarck has figured, though not very accurately.

3. G. *Nuga*. Linn. Sp. Pl. 546. (Nugæ ſylvarum; Rumph. Amb. v. 5. 94. t. 50.)—Stem ſmooth. Leaflets oppoſite, ovate, acute; the prickles on their main ſtalks in pairs. Legume ſmooth.—Native of Amboyna, only known to botaniſts by Rumphius's deſcription and plate. It is a weak trailing *ſhrub*, with a hard wood which diſtils gum when wounded. The hooked prickles on the main ſtalks of its *leaves* are very troubleſome to thoſe who walk where it grows. The *flowers* are of a fine yellow, without *bracteas*. *Legume* ſmooth and naked, containing only one or two ſquare black ſeeds.

4. G. *paniculata*. Lamarck. Dict. v. 1, 435. Willd. n. 4. (Caca Mullu; Rheede Hort. Mal. v. 6. 33. t. 19.)—Stem and leaf-ſtalks prickly. Flowers in panicled cluſters, without bracteas. Legume ſmooth, ſingle-ſeeded.—Native of watery places on the coaſt of Malabar, and other parts of the Eaſt Indies, flowering in June and July. It is as large as an apple-tree, with prickly *branches*, and bipinnate, ſmooth, firm, evergreen *leaves*, whoſe ſtalks bear ſcattered hooked prickles. *Flowers* in panicled cluſters, without bracteas, yellow. *Legume* ovate, pointed, filled with one large ſeed like a bean, of a ſhining white.

5. G. *axillaris*. Lamarck Dict. v. i. 435. Willd. n. 5. (Ban Caretti; Rheede Hort. Mal. v. 6. 35. t. 20.)—Stem and leaf-ſtalks prickly. Leaflets ovate. Flowers ſolitary, axillary. Legume hairy, ſingle-ſeeded.—Native of thick woods in Malabar, towards the mountains. *Rheede*. The *leaves* are large, ſimply pinnate, of two or three pair of ovate entire ſmooth leaflets and an odd one. *Flowers* remarkable for being ſolitary and axillary. They are of a greeniſh yellow. *Legume* like the laſt, but externally villoſe. Lamarck, with his uſual acuteneſs, has referred theſe two laſt ſpecies to *Guilandina*, of the propriety of which there can be no doubt, though they eſcaped Linnæus, who indeed ſeldom adopted any thing from plates, without ſeeing ſpecimens.

GUILD, Gild, or Geld. See Gild and Geld.

GUILDFORD, or Gildford, in *Geography*, a borough and market town of Surrey, England, conſiſts of three parithes, and is a place of antiquity and curioſity. In the time of the Saxon heptarchy it was a royal villa, and given by king Alfred to his nephew Ethelwald. Other Saxon kings reſided here. After the conqueſt it continued to be a place of note, and ſeveral monarchs occaſionally fixed their palace here. In the year 1216, the caſtle of Guildford, with others in this part of the country, were ſeized by Lewis, dauphin of France. The cuſtody of the caſtle was committed in 1267 to William Aguillon, ſheriff of Surrey and Suſſex. Since that time it has been occupied by different perſons, and has been repeatedly attacked by contending parties. The lofty thick walls of the keep-tower ſtill remain, to ſhew the ſtyle and character of the architecture. Beſides the caſtle there appear to have been a palace formerly in this town, and alſo two monaſteries, parts of one of the latter ſtill remain. Guildford appears to have been firſt incorporated by king Henry I., and as a borough ſent members to parliament in the 23d year of king Edward I. The right of election, in 1699, was veſted in the freemen and freeholders paying ſcot and lot, and reſident in the town. The number of voters, however, is only about 120, the majority of whom are under the influence of lords Onſlow and Grantley. By a charter of Henry VIII. the corporation conſiſts of a mayor, ſeven magiſtrates, and ſixteen bailiffs. Guildford gives the title of earl to the family of North. Among the eſtabliſhments in this town, is a grammar-ſchool, which is well endowed, and provided with a commodious houſe. In the year 1789 a county-hall was built here, with ſuitable offices, and at the ſame time a play-houſe was erected. The river Wey, which runs at the weſtern ſide of the town, at the foot of ſteep hills, was made navigable to this place in the year 1656, by which means a conſiderable trade in corn, malt, beer, &c. is carried on with the metropolis. In the town are three churches, reſpectively dedicated to St. Mary, St. Nicholas, and the Holy Trinity. The latter church fell down in the year 1740, but it has ſince been rebuilt of brick. The town is well provided with fairs and a market: there being three of the former yearly; and one of the latter weekly. Guildford is 30 miles S.W. of London, and contains 464 houſes and 2634 inhabitants.

GUILD-HALL, or Gild-Hall, the great court of judicature for the city of London.

In it are kept the mayor's court, the ſheriff's court, the court of huſtings, court of conſcience, court of common council, chamberlain's court, &c.

Here alſo the judges ſit upon *niſi prius*, &c.

Guildhall, in *Geography*, a townſhip of America, in Eſſex county, Vermont, on Connecticut river, containing 296 inhabitants.

GUILFORD, a townſhip of Franklin county, Pennſylvania, containing 1343 inhabitants.—Alſo, a townſhip in Windham county, Vermont, on the W. bank of Connecticut river, containing 2256 inhabitants.—Alſo, a poſt-town of Connecticut, in New Haven county, on the ſouth ſide of Long iſland ſound, about 18 miles E. by S. of New Haven city. It is large, divided into five pariſhes, and was ſettled in 1639. The Indians called it "Menuncatuck." It contains 3601 inhabitants.—Alſo, a county in Saliſbury diſtrict, North Carolina, bounded E. by Orange, W. by Rowan, S. by Rockingham county, and N. by Virginia. It is noted for the extenſive and rich tracts called New Garden, Buffaloe, and Deep river lands. It contains 9442 inhabitants, including 905 ſlaves. Its chief town is Martinville.

GUILLAUME, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the diſtrict of Paget-Theniers. The place contains 1210, and the canton 4494 inhabitants, on a territory of 485 kiliometres, in 8 communes.

GUILLEM, in *Ornithology*, the name given in many parts of England to the bird called by authors *lomwia*, and in ſome places the *kiddaw* and *ſea-hen*. See Colymbus *Troile*.

GUILLEMEAU, James, in *Biography*, a ſurgeon, was born at Orleans in 1550. He was one of the moſt celebrated pupils of Ambroſe Paré: for having entered upon the ſtudy of ſurgery with a mind cultivated by the belles lettres, and an extenſive acquaintance with the languages, the treaſures of the ancients were open to him, and he was prepared for the work of obſervation. He ſucceeded his great maſter in his practice both at Paris and in the army, and was for a long period ſurgeon to the great hoſpital, or Hôtel-Dieu, in that metropolis. He acquired ſo high a reputation that he was honoured with the appointment of ſurgeon in ordinary to the kings Charles IX. and Henry IV. He died in the midſt of his active duties and diſtinguiſhed honours, in March 1612. His works, which were not few, likewiſe contributed to raiſe his reputation. His firſt publication was a tranſlation of Treatiſe on Surgery of Ambroſe Paré into Latin, printed at Paris in 1582, folio. His next work was a ſmall treatiſe, entitled "Apologie pour les Chirurgiens," 1593. The remainder of his writings is contained in a collection of his "Œuvres de Chirurgie," printed at Paris in 1598, and in 1612; and at Rouen in 1649, ſome of which were publiſhed ſeparately. Theſe are "Tables Anatomiques,"

ques," with figures from Veſalius;—"Hiſtoire de tous les muſcles du corps humain, &c.;"—"Traité de la generation de l'homme;"—"L'heureux accouchement des femmes;"—"Traité ſur les abus qui ſe commettent ſur les procédures de l'impuiſſance des hommes et des femmes;"—"La Chirurgie Francoiſe, recueillies des anciens Médecins et Chirurgiens, &c."—"Traité des plaies recueillies des Leçons de M. Courtin;"—"Operations de Chirurgie recueillies des anciens Medecins et Chirurgiens;"—"Traité des maladies de l'œil;" and laſtly, "Traité de la parfaite methode d'embaumer les corps;" which contains a report of that operation, as performed upon the bodies of Charles IX. and Henry III. and IV. See Eloy. Dict. Hiſt.

GUILLEMITES, an order of monks in Flanders, whoſe habit reſembles that of the Ciſtercians; they follow the rule of St. Auguſtine, and are governed by a ſuperior, who does not take the title of provincial, and is elected every four years.

GUILLEMOT, in *Ornithology*. See Colymbus *Grylle*.

GUILLESTRE, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the diſtrict of Embrun; nine miles N.N.W. of Embrun. The place contains 1057, and the canton 7838 inhabitants, on a territory of 387½ kiliometres, in 11 communes.

GUILLET, de Saint George, George, in *Biography*, born at Thiers in Auvergne, was the firſt hiſtoriographer of the Academy of Painting and Sculpture; to which office he was elected in the year 1682. He was author of many works of conſiderable reputation, as "Athene Ancienne et Nouvelle;"—"Lacedemone Ancienne et Nouvelle." Theſe, it was known, were his own productions, though he pretended to have taken them from the papers of his younger brother. He publiſhed alſo "A Hiſtory of the Grand Viziers' Coprogli," &c.;—"The Life of Mahomet II."—"The Hiſtory of Caſtrucio Caſtrani," tranſlated from the Italian of Machiavel:—"Les Arts de l'homme d'Epée, ou Dictionnaire du Gentilhomme," in two volumes. He died at Paris in 1705.

GUILMAIN, Gabriel, a muſician, born at Paris in 1705. He manifeſted from his infancy a ſtrong paſſion for the violin, and acquired celebrity on that inſtrument before he was 20. In 1738 he was received into the king's band and chapel. The favour of his prince, and the love of his brethren of the ſtring, ſeemed to promiſe him a proſperous and happy old age, when, in 1770, he was unhappily ſeized with a fit of inſanity, and under a willow tree gave himſelf 14 wounds with a knife, on the road from Paris to Verſailles, near Chaville, and was interred the next day in the church yard of that village. The derangement and ſelf-ſlaughter of our poor countryman Jery Clarke of the king's chapel were ſaid to have been occaſioned by the paſſion of love; but we are not told the cauſe of the fatal cataſtrophe which at 65 terminated the exiſtence of Guilmain!

He left behind him 17 different works for the violin and harpſichord. Guilmain was one of the firſt performers, to whom the violin is obliged for the aſtoniſhing perfection to which its execution has been ſince brought. Laborde.

GUILT Rents. See Gild.

GUIMARÆNS, in *Geography*, a conſiderable walled town of Portugal, in the province of Entre Minho Douro, 1850 paces in circuit, containing ſix pariſh churches, ſix convents, four hoſpitals, fifteen ſquares, fifty-ſeven ſtreets, eight gates, four bridges, and about 6000 inhabitants; ſituated partly on an eminence and partly on a plain; four leagues S.S.E. of Braga. Here is a manufacture of linen, in high eſtimation. N. lat. 41° 25'. W. long. 7° 57'.

GUIMARAS, one of the Philippine iſlands, about 30 miles in circumference, covered with trees, and producing a great quantity of ſarſaparilla; about ſix miles from the iſland of Panay. N. lat. 40° 45'. E. long. 122° 30'.

GUIN, or Guien, a river of Africa, or rather a branch of the river Joliba, which flows from the Dibbie lake, and after purſuing a northern courſe, encloſing on that ſide the iſland Guinbala, paſſes near Tombuctoo to the S. of it, and joins the other branch of the Joliba, which paſſes ſouthward of Guinbala; and both together form the Neel Abeed, called alſo the Guin river, which purſues its courſe towards the Eaſt.

GUINALA, a town of Africa, in the country of the Biafares. N. lat. 11° 25'.

GUINBALA. See Jinbala.

GUINEA, an extenſive region in the S.W. part of Africa, which is divided into the two large countries of Upper and Lower Guinea, the latter being commonly called Congo. Theſe two, taken together, extend above 2500 miles along the ſea-coaſt. Upper Guinea is generally divided into three parts, *viz.* Malaguetta, or the Grain-coaſt, Guinea Proper, and Benin, which together extend 500 leagues from E. to W. For an account of the Grain-*coaſt*; ſee that article. Guinea proper extends from cape Palmas to the river Volta, about 140 leagues along the ſea-coaſt, which bounds it on the ſouth. It has the kingdom of Benin on the E., Gago and Melli on the N., and Malaguetta on the W. This country is divided by the Europeans into two parts, *viz.* the Tooth, Ivory, or Quaqua coaſt, and the Gold Coaſt; the former extending from cape Palmas to the river Sueira da Coſta, and the latter from thence to the river Volta. (See Ivory *Coaſt* and Gold-*coaſt*.) For an account of Benin; ſee Benin. Lower Guinea, or Congo, is bounded on the N. by Upper Guinea, or the kingdom of Benin, on the W. by the Ethiopic ocean, on the S. by the kingdom of Matamau, reckoned part of Cafraria; but on the E. and N.E. its boundaries have not been accurately aſcertained. The extent of this country from cape Lopo, S. lat. 1°, to cape Negro, S. lat. 23° 30', is about 16° 30', or about 990 Engliſh miles; its extent eaſtward is not known. It is watered by many rivers, and would be very fruitful, if it were better cultivated by the lazy negroes. The mountains abound with gold, ſilver, copper, and iron; but the mines of the latter metal are only thoſe that are worked, chiefly for the purpoſe of making arms. Congo is commonly divided into Loango, Congo proper, Angola, and Benguela. See each reſpectively.

Guinea, *New*, or Papua, an iſland of the Pacific ocean, ſituated N. of New Holland, and ſeparated from it by Endeavour ſtrait, as captain Cook has ſatisfactorily aſcertained. It is divided from New Britain in the S.E. by Dampier's ſtrait; though ſome have ſuppoſed, that in this direction the Louiſiad of Bougainville may be diſcovered to be joined, at leaſt in part, with Papua, while other parts may conſiſt of detached iſles.

Although this extenſive territory has not yet been completely inveſtigated, yet it is generally allowed to be a vaſt iſland, extending from what is abſurdly called the Cape of Good Hope, or more properly White Point in the N.W., probably to cape Rodney in the S.E., a length of more than 1200 miles by a medial breadth of perhaps 300, and thus far ſuperior in ſize to Borneo, formerly reputed the largeſt of iſlands. This iſland preſents to our notice a country, the moſt intereſting of any in Auſtralaſia, as it partakes of the opulence of the Moluccas, and their ſingular varieties of plants and animals. The land of Papua is ſaid to have been firſt diſcovered by Soavedra, a Spaniſh captain, in 1528,

who had ſailed from Mexico, by the command of Cortes to explore the Spice iſlands from that quarter. It is ſaid that Soavedra called it New Guinea, from an apprehenſion that it was under the ſame meridian with the African Guinea; but without admitting ſuch a degree of ignorance in a profeſſed mariner, it is more probable that this name was given by Le Maine near a century after, as ſynonymous with another, that of the "Iſles of Gold." On this extenſive territory, favoured by nature and no leſs enriched by the choiceſt productions, there is no European ſettlement. The inhabitants of the northern part are called Papous, whence ſprung the name of the iſland; and tradition reports that they are akin to the Moluccans. They are black, and are ſaid to have the woolly hair of negroes; but this latter circumſtance may be the effect of art; and it ſeems that in ſome parts they have the true Malay complexion and features. In the interior is a race called "Haraforas," probably Papuans of a lower claſs, who live in trees, which they aſcend by a notched pole, drawing it after them to prevent ſurpriſe. The habitations of the Papuans are built on ſtages in the water, thus reſembling the Borneans and other nations in the Aſiatic iſles. The women ſeem to be moſt induſtrious, and employ themſelves in making mats, and pots of clay, which they afterwards burn with dry graſs, or bruſh-wood: they will even wield the axe, while the men are indolent, or preparing for the chace of wild hogs. The aſpect of theſe people is hideous; the men being ſtout in body, with ſkin of a ſhining black, rough, and marked with traces like thoſe occaſioned by the leproſy, eyes large, noſes flat, mouth from ear to ear, lips, eſpecially the upper one, exceedingly thick, woolly hair, either ſhining black, or fiery red, dreſſed in a vaſt buſh reſembling a mop, 2½ or 3 feet in circumference, in which they ſtick a comb with four or five diverging teeth, and ſometimes ornamented with feathers of the birds of paradiſe; ſome increaſe their deformity by boring their noſes and paſſing through them rings, pieces of bone, or ſticks, and others, by way of ornament, wear round their necks the tuſks of boars. The heads of the women are not ſo large as thoſe of the men, and in the left ear they wear ſmall braſs rings. The men go naked, excepting a ſmall wrapper round the waiſt, made of the fibres of cocoa. The women, in general, uſe a covering of the coarſe Surat baftas, tucked up behind, ſo as to leave their bodies and thighs expoſed to view. The children have no ſort of cloathing. The religious tenets of the Papuans have not been much examined. Their tombs, made of the rude coral rock, are ſometimes marked with ſculptures. Their chief commerce is with the Chineſe, from whom they purchaſe their inſtruments and utenſils, and in return they furniſh them with ambergreaſe, ſea-flags, tortoiſe-ſhell, ſmall pearls, birds of paradiſe, lories, and other birds, which the Papuans are very ſkilful in drying. Some ſlaves, probably captives taken in war, are alſo exported. Capt Dampier, who, at an early period, made ſeveral diſcoveries on the coaſt of Papua, particularly admired the proas, which are pictureſque, and well managed. The coaſts of this country are lofty, and in the interior mountain riſes above mountain, richly clothed with woods. The ſhores abound with cocoa trees, and navigators have much admired the country, which deſerves ſuperior cultivation. Papua is the choſen reſidence of the ſplendid and ſingular birds of paradiſe, of which 10 or 12 ſorts are enumerated by Mr Pennant; they are ſuppoſed to breed in Papua, and during the dry, or weſtern monſoon, they migrate, in flocks of 30 or 40, to the iſles of Arroo. During their flight they cry like ſtarlings, but when ſurpriſed with a ſtrong gale they croak like ravens, and aſcend to the ſuperior regions of the air. They alight on the higheſt trees, ſeeming to feed on berries, and, as ſome ſay, on nutmegs and butterflies; and they are either ſhot with blunt arrows, or caught with bird-lime, or nooſes. The bowels and breaſt-bone being extracted, they are dried with ſmoke and ſulphur, ſold for nails or bits of iron, and exported to Banda. Papua alſo boaſts of elegant parrots and lories; and the crowned, or gigantic pigeon, almoſt equals a turkey in ſize.

Some of the ſmall iſlands adjacent to this comparative continent, are better known than the main land of Papua. At the N.W. extremity the chief iſles are Waijoo and Salwatti; and the ſmaller iſles of Wolcket, Famia, Piamis, Wagiol, Laib, Wiag, and Sinag, ſerve to fix the boundary between Auſtralaſia and the iſlands in the Oriental Archipelago; Gag and Gibbi, from their proximity to Gilolo, belonging to the latter. Farther to the S. are the Papuan iſlands of Arroo and Timorlaut, the boundary here paſſing on the E. of Nila, one of the ſmall Aſiatic iſles, among which Serro muſt be claſſed. On the E. of Benda the boundary may paſs to the S. of Mamabek, then winding N.W. to the E. of Myſol, will leave Popo in the Oriental Archipelago, while Wolcket claſſes with the Papuan iſlands. Pinkerton's Geog. vol. ii.

GUINEA, a gold coin, ſtruck and current in England.

The value, or rate of guineas, has varied: this coin was firſt ſtruck at the value of twenty ſhillings; by the ſcarcity of gold, it was afterwards advanced to twenty-one ſhillings and ſix-pence; but it is now ſunk to twenty-one ſhillings. The pound weight troy of gold is cut into forty-four parts and a half; each part makes a guinea. See GOLD, STANDARD, and MONEY.

This coin took its denomination, *guinea*, becauſe the gold, whereof the firſt was ſtruck, was brought from that part of Africa, called *Guinea*; for which reaſon it likewiſe bore the impreſſion of an elephant.

GUINEA *Company*. See COMPANY.

GUINEA *Hen*. See NUMIDA *Meleagris*.

Guinea hens naturally herd together in large numbers, and breed up their young in common; the females taking care of the broods of others, as well as of their own. They breed very well with us. Their fleſh is tender and ſweet; generally white, though ſometimes black. They are not ſo tame and domeſtic as our own fowls, and particularly they will not lay in houſes, but get into the hedges and among buſhes, where they lay and hatch; but this is the occaſion of great loſs among them, the wild vermin deſtroying a great part of their young brood. The female alſo is leſs careful about the great buſineſs of hatching and taking care of them, than any other bird we are acquainted with: the beſt method, therefore, is to ſet other fowls upon the eggs of this kind. The young fowls of this kind are very beautiful; they look like ſo many partridges. Their beaks and legs are red, and their whole plumage is at that time of the colour of the partridge.

The hen, if her neſt is found, and the eggs at times taken away, but ſo as always to have one there, will continue to lay till ſhe has depoſited a hundred, or ſometimes a hundred and fifty eggs, which are very well taſted. This is a very active and ſprightly bird, and of an unquiet and troubleſome diſpoſition to the owner. It runs very ſwiftly, in the manner of the quail and partridge; but its wings are ſhort, and it is not made for flying; yet at night it will not rooſt among other fowl, but gets upon a houſe or tree, or any other high and ſafe place. The cry of the bird is ſharp and diſagreeable to many ears, and it is almoſt continually making it. It is of a quarrelſome diſpoſition, and will be miſtreſs of the yard: its agility, and the ſharpneſs of its beak, generally obtain it the victory with whatever bird it fights. The *pin-*

todo is so common in America, that many have supposed it native there: but this is not the case: the origin of the bird is in Guinea, where they are found in flocks of two or three hundred, that perch on trees, and feed on worms and grasshoppers; and the first that were ever brought into America, were brought in the year 1508, with the cargoes of negro slaves. The Spaniards, neither at that time, nor ever since, have attempted to tame them, or render them domestic, useful birds, but let them go loose and wild in the savannas, where they have increased to such prodigious numbers, that they may well appear native, and are seen in vast flocks together, and are called *marroon pintades* by the Spaniards and French. Observ. sur les Cout. de l'Asie, p. 190.

GUINEARA, in *Geography*, a town of Hindoostan, in the circar of Ruttunpour; 10 miles S.W. of Ruttunpour.

GUINES, a town of France, in the department of the Straits of Calais, and chief place of a canton, in the district of Boulogne; 6 miles S. of Calais. The place contains 2600, and the canton 11,482 inhabitants, on a territory of 157½ kiliometres, in 17 communes.

GUINET, or GWYNNED, a township of America, in Montgomery county, Pennsylvania, containing 906 inhabitants.

GUINETTA, in *Ornithology*. See TRINGA *Hypoleucos*.

GUINGAMP, in *Geography*, a town of France, in the department of the North coast, and principal place of a district. N. lat. 48° 33'. W. long. 3° 4'. The place contains 5190, and the canton 12,248 inhabitants, on a territory of 142¾ kiliometres, in 8 communes.

GUINIAD, or GWINIAD, *i. e. whiting*, so called on account of the whiteness of its scales, the *salmo lavaretus* of Linnæus, in *Ichthyology*, is a name given by some to the fish known among authors by the name of *ferra*, a fish of the truttaceous kind, common in the lakes of Wales, particularly in that called Llyntegid, near Bala, in Merionethshire, and some of the northern counties of England; and in the last of these places called the *schelley*. It is also found in the lakes of Switzerland, Italy, Norway, Sweden, Lapland, Scotland, and Ireland. The head is small, smooth, and of a dusky hue; the eyes large, the nose blunt at the end, the jaws of equal length, the mouth small and without teeth; the branchiostegous rays nine; the covers of the gills silvery, powdered with black; the back is a little arched, the colour glossed with a deep purple and blue, but near the lateral lines assumes a silvery cast tinged with gold; the side-line is straight, and is formed of distinct spots of a dusky hue; the belly is a little prominent, and quite flat at the bottom; the first dorsal fin, near the middle, consists of fourteen branched rays; the second is near the tail, and is thin and transparent; the pectoral fins have eighteen rays, the ventral twelve, and the anal fifteen, which are all branched at their ends; the tail is much forked; the scales are large, and adhere to the body.

The guiniad has an insipid taste, and will not keep long. Their spawning season in Llyntegid is in December. Camden observes, that this fish never wanders into the river Dee, and that the salmon never ventures into the lake: this is generally, but not universally, the case. Pennant, and Phil. Trans. vol. lvii. for 1767, p. 211.

GUINNETII, JOHN, in *Biography*, was a native of Wales, of very poor parentage, but supported in his studies by a beneficent clergyman, who allowed him an exhibition. In 1531, being then a secular priest, and having spent twenty years in the study and practice of music, and composed the responses for the whole year in division-song, and many [illegible]ffes and antiphons for the use of the church, he supplicat[illegible] r the degree of doctor, and obtained it upon payment of twenty-pence; and in 1533 he was presented to the rectory of St. Peter, in West Cheap. He wrote "A Declaration of the state wherein Heretics do lead their lives," and other controversial tracts mentioned by Wood and Tanner.

GUINTHER, JOHN, or GUINTERIUS, was born in 1487, at Andernach, a small town in Germany, in the circle of the Lower Rhine. His real name was *Winther*. He was of obscure birth, but evinced his zeal for knowledge from his child-hood. At twelve years of age he went to Utrecht, where he studied the belles-lettres, and particularly the Greek language with great ardour; but his scanty means were insufficient for his support, and he went to Deventer, where he lived some time by the assistance of such as commiserated his situation, and is even said to have been compelled to beg his bread. But labour and industry having enabled him to overcome the hardships of fortune, he went to Marpurg, with the intention of cultivating natural philosophy. Here he gave such public proofs of his erudition, that he was engaged by the inhabitants of Goslar to instruct their young people; but he soon quitted this employment, to accept one more suited to his talents, having been appointed professor of Greek at Louvain. His disposition, however, inclined him to the profession of medicine; and, after a time, he repaired to Paris, at that period the most flourishing school of medicine in Europe, where his merit procured him the patronage and friendship of several distinguished persons, especially of cardinal Du Bellay, for whose zealous kindness he ever after retained the most lively gratitude. Guinther was 37 or 38 years of age when he went to Paris in 1525. He took the degree of bachelor in 1528, and of doctor in 1530, when half the expences were remitted to him. Though a foreigner, he was appointed physician to Francis I., and practised his profession in Paris during several years. He also gave private lectures on anatomy, and is said by some of his biographers to have made some discoveries in that science; Winslow, in a thesis maintained in 1717, calls him "Primus Anatomes in Academia Parisiensi Restaurator Guinterius Andernacus;" nevertheless, Vesalius speaks contemptuously of his anatomical skill.

The reputation of Guinther had reached the north of Europe, for he was invited by Christian III. of Denmark, who made him the most advantageous offers, to repair to his court. But in 1537, the disturbances which took place on the score of religion, compelled him to quit that kingdom, which he now regarded as his own country. He retired to Metz, whence the war soon compelled him to pass to Strasburgh. Here he was received with honour by the magistrates, and had a chair assigned him by the faculty; and he practised with great success and reputation; his visits extended at times over the greater part of Germany, and even into Italy. At length, letters of nobility were gratuitously conferred on him by the emperor Ferdinand I. He lived, however, but twelve years to enjoy these honours, being seized with an ardent fever, at the house of a noble patient; whence he was carried home, and he died on the 4th of October, 1574, at the age of 87.

The works of Guinther are numerous, consisting partly of translations of the best writings of the ancient physicians, and

and principally of commentaries and illuſtrations of them, and of the ſubjects of which they treat. For a catalogue of the titles of his works, we muſt refer the reader to Eloy, who has occupied ſeveral pages in detailing them, together with brief notices of the works themſelves. See his Dict. Hiſt. de la Medicine.

GUIOA, in *Botany*, ſo denominated by Cavanilles, in honour of Joſeph Guio and Sanchez, who in his voyage along with Louis Née, made many beautiful and accurate coloured botanical drawings. Cavan. Ic. v. 4. 49. Claſs and order, *Octandria Monogynia*. Nat. Ord. *Sapindi*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five roundiſh concave, equal, permanent leaves. *Cor.* Petals five, ſhorter than the calyx and alternate with it, obovate, inſerted into the outſide of an annular nectary, which is fleſhy, and obſcurely five-ſided. *Stam.* Filaments eight, awl-ſhaped, equal, ſhorter than the calyx, inſerted into the inner ſide of the nectary; anthers incumbent, ovate, two-celled. *Piſt.* Germen ſuperior, ſomewhat ſtalked, ovate, triangular; ſtyle very ſhort; ſtigma awl-ſhaped, ſimple. *Peric.* Capſules three, coriaceous, compreſſed, rounded, ſpreading, affixed laterally to the central column, each of two valves and one cell. *Seeds* ſolitary, lenticular, affixed to the baſe of the column, in a membranous arillus.

Eſſ. Ch. Calyx five-leaved. Petals five, ſmaller. Stigma ſimple, acute. Capſules three, compreſſed, of two valves, and one cell. Seeds ſolitary, in a membranous arillus.

1. G. *lentiſciſolia*. Cavan. Ic. t. 373. A *ſhrub*, ſix feet or more in height, found in *Babao*, one of the Friendly iſles, not far from the ſea-ſide, flowering in June and July. *Leaves* alternate, abruptly pinnate, compoſed of three pair of elliptic-lanceolate, ſtalked, entire leaflets, of a coriaceous texture and ſmooth ſurface. *Flowers* ſmall, in terminal compound panicles, reddiſh.

Nearly allied to the *Molinæa* of Commerſon and Juſſieu, but the three ſeparate bivalve capſules ſeem, by the figure and deſcription, to render it generically diſtinct.

GUIOLE, LA, in *Geography*, a town of France, in the department of the Aveyron, and chief place of a canton, in the diſtrict of Eſpalion; 24 miles N.N.E. of Rhodez. The place contains 1973, and the canton 5176 inhabitants, on a territory of 222½ kiliometres, in 9 communes.

GUIOMERE, a kingdom or country of Africa, on the Ivory coaſt, near cape Apollonia, having narrow limits towards the ſea, but extending itſelf towards the inland parts: it is rich and populous, furniſhes conſiderable quantities of gold and ivory, and afforded formerly, by perpetual wars, a plentiful market of ſlaves.

GUIPUSCOA, a diſtrict of the province of Biſcay, in Spain, of a triangular form, and ſo mountainous, that it may be conſidered as one continued mountain. It is bounded on the N. by the bay of Biſcay, and the gulf of Gaſcony; on the E. by Navarre and Lower Navarre, in France; on the S. and S.E. by Alava, and on the W. by the country of the Four Towns, which is long and narrow, incloſed between the lordſhips of Biſcay, Guipuſcoa, Old Caſtile, and Alava, and which ſeparates Guipuſcoa from Biſcay Proper. It is 18 leagues from W. to E., and 12 from N. to S. Its capital is Toloſa, and its other towns are Vergara, Placencia, Fontarabia, and St. Sebaſtian. The coaſt of this diſtrict, or province, is about 10 leagues in extent, in which are three principal parts, viz. Fontarabia, Los Peſages, and St. Sebaſtian. Its chief rivers are, the Bidazoa, the Deva, the Urola, the Oria, the Uramea, and the Araxes; and, like Alava, it is watered by a great number of ſtreams and brooks: the Zaraya divides theſe two diſtricts. Guipuſcoa enjoys the ſame privileges as the lordſhip of Biſcay, except, that, as frontier of the kingdom, it receives garriſons, and is defended by fortified towns. It was independent of the crown of Caſtile till the year 1200, when, of its own accord, it ſubjected itſelf to Alphonſo VIII. The inhabitants of this country have always made their own laws; and there are extant treaties concluded between them and foreigners, relative to war and peace. Their two principal privileges are; 1ſt, that of the voluntary tax, or gratuitous gift, which amounts annually to 31,250*l.*; 2dly, of not being liable to the quintos, a levy of men, by which the crown of Spain claims one out of every five.

The climate of Guipuſcoa is tolerably mild and temperate, on account of the ſea-breeze which refreſhes the air in ſummer, and ſoftens it in winter. The wheat produced in this country is not ſufficient for the conſumption of its inhabitants. Grapes have degenerated; but there are orchards of apples which yield very good cyder. Foreſts and woods abound; ſuch as oaks, beach, cheſnuts, aſh, walnut, poplar, elm, and lime. Where theſe trees do not prevent, the land is every where cultivated, and produces pulſe, maize, turnips, flax, &c. The cultivation of trees is well underſtood and much practiſed in this country. There are fifteen iron forges in this diſtrict. The commercial company eſtabliſhed at Sebaſtian by Philip V. in 1728, under the names of Caraccas and Guipuſcoa, has done infinite ſervice, by procuring for Spain an important branch of trade, which was in the hands of the Dutch. This company, however, was ill-managed, and ſuſtained a conſiderable loſs at the commencement of the war between England and America, in conſequence of which it ſunk, and was depreſſed.

GUIR, a river of Fez, which runs into the Atlantic; N. lat. 33° 45′.

GUIRACA, a ſea-port of South America, in the province of St. Martha; 15 miles E. of St. Martha.

GUIRA-ACANTAGARA, in *Ornithology*, the name of a Braſilian bird of the wood-pecker kind, and of the ſize of our large ſpotted wood-pecker. See Cuculus *Guira*.

GUIRA-BERABA. See Motacilla *Guira*.

GUIRACENOIA. See Tanagra *Braſilienſis*.

GUIRAQUEREA. See Caprimulgus *Jamaicenſis*, and *Torquatus*.

GUIRARU-NHAENGETA. See Lanius *Nengeta*.

GUIRATANGEIMA. See Oriolus *Icterus*.

GUIRATINGA. See Heron.

GUIRATIRICA. See Loxia *Dominica*.

GUIRAUPIAGARA, in *Zoology*, the name of a ſpecies of ſerpent found in America, and ſo called from its love of eggs, the word expreſſing a devourer of eggs. It is a long ſlender ſnake, black on the back, and yellow on the belly; it is a great climber of trees, and rolls about among their upper branches, as ſwiftly as if ſwimming in water; it is a great enemy to birds, deſtroying vaſt quantities of their eggs. Ray's Syn. Animal. p. 329.

GUIRGHIN, in *Geography*, a town of Africa, in the kingdom of Fonia. N. lat. 12° 15′. W. long. 16°.

GUIRON. See Giron.

GUISA, in *Geography*, a town of the iſland of Cuba; 35 miles N. of Trinidad.

GUISARD, Peter, in *Biography*, a phyſician, was born in 1700, in the neighbourhood of Montpellier, and educated in the Proteſtant religion. He contended, with great credit,

credit, for one of two vacant profeſſorſhips at that place in 1731, but was unſucceſsful. He afterwards had the offer of the chair of Dr. Marcot, who was called to court; but it was neceſſary that the profeſſor who held it ſhould be a Roman Catholic. On this condition he declined it; but having ſeriouſly examined the tenets of that religion, he afterwards embraced it. He then went to Paris, where he practiſed with great reputation; but his love for his country induced him to return to Montpellier, where he died on the 17th of September, 1746, in the 46th year of his age. He left three works, *viz.* "Quæſtiones Medico-Chirurgicæ duodecim pro Cathedra regia vacante," Montpel. 1731. "Practique de Chirurgie, ou Hiſtoire des Plaies, &c." 1733; and laſtly, "Eſſai ſur les Maladies Veneriennes," 1741. Eloy. Dict.

GUISCARD, Robert, duke of Apulia and Calabria, the ſeventh ſon of Tancred, a gentleman of Lower Normandy, was born towards the commencement of the 11th century, and was diſtinguiſhed amidſt a family of warriors by his vigorous and enterpriſing ſpirit in the exerciſes of the camp. His elder brothers had all paſſed into Italy, and by their merit had attained the dignity of chiefs. Robert, as deſirous of fame as any one of them, followed their ſteps, croſſed the Alps as a pilgrim, and raiſed a band of ſoldiers from the adventurers of Italy. His early ſucceſſes againſt the Greeks and natives of Calabria, cauſed a number of Norman volunteers to flock to his ſtandard. He, by his own influence, procured his elevation to the dignity of count and general of the military republic. He proceeded in the conqueſt of Calabria; but, in conſequence of ſome exceſſes, incurred papal excommunication. The breach was ſoon healed, and Nicholas II. inveſted him with Apulia and Calabria, and all the lands in Italy and Sicily, which he could conquer from the Greeks or Saracens. About this period, Robert aſſumed the title of duke of Apulia, Calabria, and afterwards of Sicily. He employed great vigour and activity in reducing the maritime cities which held out for the Greeks, and at length made himſelf maſter of almoſt the whole that conſtitutes the modern kingdom of Naples. In 1081 he invaded the Eaſtern empire, but underwent many loſſes from ſhipwreck and the enemy; and his ſon Bohemond, who commanded the naval force, was defeated by a Venetian fleet. Under theſe difficulties, the emperor Alexius Comnenus marched againſt him with an army greatly ſuperior in numbers. Robert, however, gained the battle of Durazzo, and the town ſurrendered. In this engagement, Robert's wife, Gaita, daughter of the prince of Salerno, fought by his ſide. The emperor, Henry IV., who had marched towards Apulia to make a diverſion in favour of Alexius, afterwards turned his arms againſt pope Gregory VII., and making himſelf maſter of Rome, inveſted the pontiff in the caſtle of St. Angelo. Robert, conſidering himſelf a vaſſal of the holy Roman ſee, marched, in 1084, to his relief; but the emperor, dreading the terror of his name, did not venture to wait his approach. Robert liberated the pope, who accompanied his deliverer back to Salerno, where he died. In the cloſe of the ſame year he made a ſecond expedition into Greece, and defeated the united fleets of the Greeks and Venetians in three engagements. He next turned his arms againſt the maritime parts of Greece, and the adjoining iſlands, but an epidemic diſorder ſtopt his career, and he died in the iſland of Cephalonia, July 1085. He was, as we have ſeen, a perſon of great civil and military talents, brave and politic; hence he obtained the ſurname Guiſcard, from a word ſignifying craft or prudence in the Norman dialect. According to his biographers his ambition was but little tempered either with humanity or a ſenſe of juſtice: he purſued his own aggrandizement with ſteady ſteps. He was affable, and courteous to his companions in arms, plain in his dreſs and manners, rapacious in acquiring wealth, and liberal in beſtowing it.

Guiscard, in *Geography*, a town of France, in the department of the Oiſe, and chief place of a canton, in the diſtrict of Compiegne; 5 miles N. of Noyon. The place contains 1287, and the canton 9436 inhabitants, on a territory of 187½ kiliometres, in 26 communes.

GUISCHARD, Charles Gottlieb, in *Biography*, called Quintus Icilius, was born at Magdeburg, where his father was a chief magiſtrate. Having completed the elementary parts of his education, he ſtudied at the univerſities of Halle, Marpurg, and Leyden, where he applied to the claſſics, theology, and the oriental languages. By the intereſt of the ſtadtholder, he was appointed enſign in a regiment in the ſervice of the United Provinces, and in 1751 he was promoted to a company. Encouraged by the prince, whoſe patronage he expected, he reſolved to diſtinguiſh himſelf by ſome literary labour, and began to collect and prepare materials for his "Memoirs Militaires ſur les Grecs et les Romans." In conſequence of this undertaking he obtained permiſſion to viſit England, where he remained a year, and brought the work to a concluſion. In the mean time, the ſtadtholder died, and with a view of obtaining the favour of his ſucceſſor William V., he dedicated his memoirs to him. They were publiſhed in two volumes quarto, were received with much approbation, and went through five editions in France and Holland. In 1757 he entered as a volunteer in the allied army, acquired the eſteem of Ferdinand of Brunſwick, and was recommended to the notice of Frederic II. of Pruſſia, who ſent for him to Sileſia, kept him near his perſon, and often converſed with him on the art of war, as practiſed by the ancient Greeks and Romans. On account of his great knowledge on this ſubject, he was ſo highly eſteemed, that the king gave him the name of Quintus Icilius, the commander of Cæſar's tenth legion, when he appointed him to the command of a regiment formed out of the refuſe of all nations, during the heat of the war. Guiſchard greatly diſtinguiſhed himſelf, and continued till the end of the war to diſcharge, amidſt much danger, the arduous taſks aſſigned him. At the general peace the king retained him at Potſdam, and he was one of the few perſons whom his majeſty admitted into his convivial parties; and to whom he gave the freeſt acceſs to his library and coins, which latter Guiſchard increaſed ſo much, that he valued both at the ſum of a hundred thouſand dollars. His former courſe of life, and the hardſhips to which he had been expoſed by his profeſſion, brought on infirmities, which became ſo painful to him, that he was accuſtomed to compare them to the torture of the rack, and which at length put an end to his exiſtence. He died on the 13th of May, 1775, in the fifty-firſt year of his age. Frederic purchaſed his library of his heirs for the ſum of 12,000 dollars. Beſides the work already mentioned, he was author of "Memoires Critiques et Hiſtoriques ſur pluſieurs Points d'Antiquités Militaires," in four volumes, octavo. This work is regarded as particularly uſeful to young people in ſtudying ſome of our beſt claſſics, particularly Cæſar's Commentaries.

GUISE, Francis de Lorraine, duke of, was eldeſt ſon of Claude de Lorraine, duke of Guiſe, and was born at the caſtle of Bar, in 1519, and early diſtinguiſhed himſelf in arms. He acquired great glory in the defence of Metz in 1553, againſt the emperor Charles V. He was afterwards declared by Henry II. lieutenant-general of the kingdom,

kingdom, and entrusted with all the authority of the crown. In 1558 he took Calais, which had long been in the hands of the English, and which had served as an entrance into France, in the wars between the two countries. At the accession of Francis II., whose wife, Mary, queen of Scots, was niece to the Guises, the duke and his brother the cardinal were placed at the head of the government. At this period the Calvinists, headed by the prince of Condè, engaged in the conspiracy of Amboise, and its defeat was chiefly owing to the vigilance of the duke of Guise, who was lieutenant-general of the kingdom. This victory was not used with much moderation, and a great number of executions followed: Condè would unquestionably have shared the same fate, had not the demise of the king prevented it. After this event the influence of the Guises abated, and they formed only one of three parties, which were balanced by the art of Catharine de Medicis. Liberty of conscience, and the right of public worship according to their own views, were granted to the Calvinists, a measure particularly mortifying to the bigotry of the Guises. At this period, the duke was the cause of a terrible massacre of Protestants at Vassy, who had assembled there for the purposes of divine worship. When the magistrate, who was called before the duke, excused himself for permitting this religious assembly, upon the ground of the edict of toleration, Guise, in a rage, clapping his hand to his sword, exclaimed, "here is what shall cut the knot of your detestable edict." The massacre was a signal for civil war, and the duke was the chief on the Catholic side, and he was, deservedly, the principal object of the hatred of the persecuted Protestants. History, however, records a fact highly to his honour, but which, it must be admitted, little accords with the practice of the duke, or with the principles of the religion, as they were at that time avowed. A fanatic was taken who had formed a plan of assassinating him. The man was brought before him, and asked what offence he had given him to excite such an attempt. "No other," replied the enthusiast, "than that of your being the inveterate enemy of my religion." "Well," said the duke, "if thy religion bids thee murder me, mine commands me to forgive thee: judge between them." The victory of Dreux, in 1562, is chiefly ascribed to Guise; in this the prince de Condè was taken prisoner, and, according to the manner of the age, shared that night the duke's bed: though they were mortal enemies, the duke slept soundly all night, while the prince could scarcely close his eyes. Not long after this, he was shot by a Calvinist gentleman, as he lay before Orleans. He died February 24, 1563, at the age of forty-four. By writers on his own side he is represented as the model of true heroism, but his good qualities were undoubtedly very much balanced by a furious party-spirit, and by an immoderate ambition that brought great evils on his country.

GUISE, HENRY DE LORRAINE, duke of, eldest son of the preceding, born in 1550, was distinguished by his great valour, and a duel which he received, and which left a great scar on his cheek, gave him the name of Balafre. By his engaging manners he became the idol of the army and people. He at length aspired to nothing less than supreme authority; evaded the revocation of every privilege granted to the Protestants, demanded the publication of the decrees of the council of Trent, the establishment of the inquisition, and the option of five cautionary towns. He obtained great success against the Protestants, and was regarded by the Catholics with an enthusiastic attachment, as the deliverer of the nation. The party grew insolent by success, and they openly avowed that they would dethrone the king. The duchess of Montpensier, sister to the Guises, carried at her girdle a pair of golden scissars, which she did not scruple to declare were designed to give the king the clerical tonsure, previously to shutting him up in a convent. In 1588 the states-general of the kingdom were assembled at Blois. The demands of the leaguers became more and more audacious, and Henry evidently tottered on the throne. The king now began to concert measures to free himself of his rival; he is said to have distributed with his own hands poignards to chosen men of his guards. Guise heard of the plot, and laughed at its impotency; but as he advanced to the presence chamber, even at the door of the cabinet, in which the king was, he was suddenly pierced with many stabs. He fell, exclaiming "my God, have mercy on me!" His brother, the cardinal, who had encouraged him in all his ambitious projects, was seized and put to death the next day. So bitter was the hatred of their enemies, that they did not rest contented till they had literally burnt their bodies to ashes, lest their adherents should make relics of their remains. He was at his death thirty-eight years of age. He resembled his father in civil and military qualities, but was much more criminally ambitious. With religion ever in his mouth, his conduct was excessively licentious.

GUISE, HENRY DE LORRAINE, duke of, grandson of the preceding, born in 1614, was brought up to the church, and from his connections was provided with much preferment, which he resigned at the death of his elder brother. Inheriting the qualities of his ancestor, he entered into a conspiracy against the French government, which being discovered before it was ripe for execution, he was obliged to retire to Rome. While in that city he received an application from the Neapolitans, who had revolted from Spain, to come and assume the chief command. He readily embarked, and arrived at Naples in November 1647. Here he quickly established his authority, and marching out of Naples with a small army, he took possession of Aversa, and gained several advantages over the Spaniards. He next established a regular government, and became exceedingly severe and despotic in his administration. He expected to become king of Naples and Sicily, of which the pope had offered the investiture, instead of which, he was taken by the enemy, and kept prisoner in Spain four years, when he was set at liberty through the intercession of the prince of Condè. In 1654 he embarked in a new expedition fitted out by the cardinal Mazarin, for the recovery of Naples, but it was attended with no success. After this he was employed at court, obtained the post of chief chamberlain, and was the person delegated to receive Christina of Sweden on her entrance into France. His manners were now so softened down, that he shone in the business of a courtier, but some part of his conduct proved that he had little of the principle of true honour in him. He died in 1664. His memoirs on the Neapolitan enterprize were published in one volume quarto.

GUISE, WILLIAM, an English divine, was born at Abbeadl's court, near Gloucester, in the year 1655. Having laid in a good stock of elementary learning, he was entered a commoner of Oriel-college, Oxford, whence he was removed to All-souls' college, of which he was chosen fellow. Here he took his degrees, and obtained the reputation of a first-rate scholar, particularly in Oriental learning. He died at the age of thirty, in the year 1683, of the small pox, before he had scarcely began to apply his vast stores of knowledge to the public service. His posthumous work is "Miscellaneæ Pars; Ordinis primi Zeraim Tractatus Septem, La-

tine

tine vertit et Commentario illuſtravit Gulielmus Guiſius, 1690." The editors of the "Acta Eruditorum," pronounced the author to be a man of profound learning, and an immortal ornament to the univerſity of Oxford. He had, when he died, undertaken an edition of Abulfeda's Geography.

GUISE, in *Geography*, a town of France, in the department of the Aiſne, and chief place of a canton, in the diſtrict of Vervins, ſituated on the Oiſe; 20 miles N. of Laon. The place contains 3039, and the canton 13,998 inhabitants, on a territory of 160 kiliometres, in 22 communes.

GUISHDEN, a river of Ireland, in the county of Mayo, which flows into Lough Conn.

GUISO, a town of Japan, in the iſland of Niphon; 10 miles N. E. of Meaco

GUITARRA, Spaniſh; *Guitarre*, Fr.; *Chitarra*, Ital.; *Guitar*, Engl. all derived from *Cithara*, which ſee.

The Spaniſh guitarra is of a much larger ſize than the chitarra of Italy, or the guitarres uſed in France or England. It is ſtrung with bowel-ſtrings, and, in form, it ſeems to have been conſtructed on a ſection of a pumpkin or gourd, to which is adjuſted a belly of deal, and a neck at the upper part of the body of the inſtrument. It has ten frets, dividing each ſtring into ſemitones: of theſe the tenſion muſt be extremely tight round the neck, for fear of their giving way.

The ſtrings are faſtened to a bridge fixed to the lower part of the belly, and ſupported by a nut at the end of the neck. The ſtrings are governed by pegs or metal pins at the back of the neck. The inſtrument had at firſt but four ſtrings, which have ſince been encreaſed to five double ſtrings, of which the three firſt are tuned uniſons, and the fourth and fifth octaves to each other. Sometimes the fifth ſtring has no octave leſt it ſhould overpower the reſt; and the firſt ſtring is ſo often falſe that it is frequently played ſingle.

This inſtrument is tuned and played ſo many different ways, that it muſt be ſtrung according to the pitch and tuning.

In compaſs it is two octaves and a fifth, from A in the firſt ſpace in the baſe, to E in the fourth ſpace in the treble.

The tuning, like that of the lute, is entirely by fourths, except one major third: A D G B E.

The tablature of the guitar in Spain and Portugal is ſtill the ſame as that of the lute; but in moſt other countries, its notation is the ſame as for the harp or pianoforte.

In the ancient tablature, letters of the alphabet, or ciphers, were uſed for the melody and accompaniment. This method, though ancient, is preſerved for the convenience and carriage of the hand, the arrangement of the fingers, the clearneſs of the tone, the harmony and facility of execution. If this inſtrument is not ſtudied as much as the harpſichord or pianoforte, it is hardly poſſible to find the poſitions of the hand with ſufficient readineſs.

In France they uſe the firſt eleven letters of the alphabet, placed *a* to *l* upon each ſtring for the ten frets, which produce chromatic ſemitones, leaving off from the open ſtring at *a*, that is, without touching the ſtring with the finger, which is expreſſed by an *a*; the firſt fret by a *b*, and the other reſpectively.

Theſe ſigns are alſo uſed for the fingers of the two hands; that of the left-hand, which is occupied with every part of the baſe, is ſometimes alſo, thus ⌒, when the notes muſt be played from the ſame to paſſing from note to note, deſcending; and ⌒ when the notes are to be played aſcending. This is done by letting the fingers fall on

the ſtrings with ſpirit and force; ſo that the firſt touch of the ſtring by the end of the finger ſhall produce the ſound. The wavering, unſteady and plaintive tone, produced by the preſſure of the finger, for the continuance of the tone, reſembles what is called a cloſe ſhake on the violin: the ſhakes, beats, and ſhifts to form a moveable nut from fret to fret, will require long practice.

The ſigns for the right hand, which ſerves as a kind of bow, and of which the execution is upon the belly of the guitar, are little ſtraight lines | , or ſemicircles, placed under the letter which ought to be touched with the thumb; the points :::: which are placed under thoſe to be touched with the firſt, the ſecond, and third finger, are indications for taking off or keeping on the finger in arpeggios. There are marks for ſweeping the chords upwards, and others downwards. The tails downwards imply ſtriking the notes from top to bottom, and upwards the contrary.

As to the notes expreſſed by the letters placed on the five lines or ſtaff, which are to be pinched or thrummed, they repreſent the five ſtrings of the guitar. When many letters follow each other, of the ſame value, only one note is written for the firſt of them: for example, one quaver or crotchet for the whole bar, and even many bars of which the notes are of the ſame kind, till another note ſucceeds of greater or leſs value. In this reſpect the ſame ſingle characters are uſed as in other muſic, and the ſame reſts, &c.

There are two ways of performing on this inſtrument, either by ſweeping or pinching the ſtrings; many affect one way more than the other; ſome uſe both ways, occaſionally, which is preferable. The moſt extenſive, and the moſt ſuſceptible of execution, is the pinching of the ſtrings. The arpeggios are more harmonious, becauſe all the ſtrings are in vibration; but they muſt be touched very lightly and delicately with the right hand, and with firmneſs, and correct poſition of the left hand, to produce a good effect; for nothing is ſo eaſy as to metamorphoſe this inſtrument, of which the harmony may be rendered ſo ſweet, into a mere kettle.

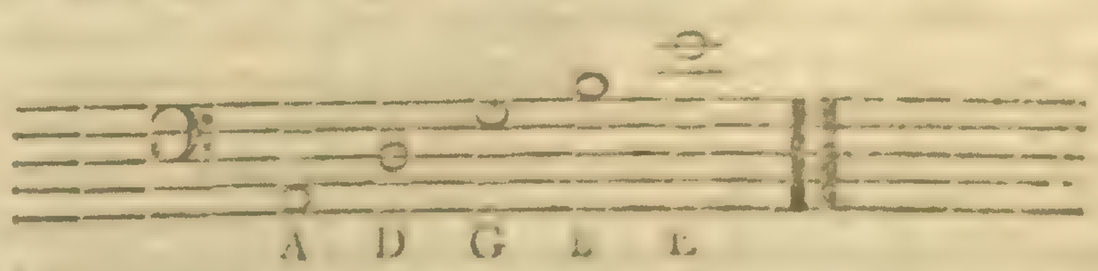
The ſtrings are pinched or thrummed between the roſe and the bridge; but the arpeggios ought to be made between the roſe and the laſt fret of the neck, that is, about the middle of the ſtrings, to avoid the harſhneſs reſulting from the playing too near the bridge, where the ſtrings are more ſtubborn and unmanageable than towards the middle.

Of the Strings.—The choice of ſtrings requires great care, for their ſize, proportions, and truth, eſpecially for the uniſons, of which, if either is falſe, they never can be tuned.

The ſilvered, or whipped ſtrings, have two inconveniences: the one is of wearing out and cutting the frets: the other, ſtill greater, of overpowering the other ſtrings, particularly in ſweeping the chords.

There are indeed chords in which they have a good effect, when they give the fundamental baſe; but as that does not happen very frequently, the ſilvered ſtrings muſt be touched very gently.

The following repreſentation of the neck of the large Spaniſh guitar will ſhew how the inſtrument is tuned.



Obſervations on the Repreſentation of the Neck or Finger-board of the Guitar.—The names of the notes are written on the neck, at the place over which the fingers are to fall, the

neareſt

neareſt to the fret poſſible, but never above the fret. No finger muſt be near the nut marked *a*, becauſe the tone of the open ſtring begins there, and it is by the open ſtrings that the inſtrument is tuned.

In the progreſſion of the octave, by half-notes, no flats appear in the ſcale given, ſharps only being marked to avoid confuſion; but thoſe ſharps would be flats in other keys: beginning, for example, at B♭, and mounting by half-notes, no ſharps would be wanted.

As to the form of the letters uſed as repreſentatives of notes, they are Gothic, particularly 6 and Γ; and the long letters lean a little to prevent their mixing with each other. This notation is very ancient, and the ſame as that of the lute, 2 or 300 years ago. See MACE. See *Plates* VII. and IX. *on Muſic*.

This guitar is ſuperior in tone, expreſſion, and power, to the common guitar ſtrung with wire. About 45 years ago, ſoon after the conſpiracy at Liſbon, of Malagrida and others, a Portugueſe gentleman, or muſician, with the appearance of a gentleman, of the name of Meneſis, probably involved in the plot, reſided ſome time in London, ſeemingly as a man of faſhion, who performed in a very ſuperior manner on the large Spaniſh guitar ſtrung with cat-gut or bowel-ſtrings. He was ſo great a maſter of the inſtrument, and ſo able a muſician, that he played voluntaries upon it in the ſame full and learned manner of a great performer on the organ; led off ſubjects, purſued them in three and four parts with ſcience and fancy through all the keys of legal modulation; and in ſlow movements, his taſte and expreſſion were equally admirable with the learned and maſterly effuſions of his allegros.

This is not a traditional account, for we were ſo fortunate ourſelves, as to hear him perform at lord Eglington's with lord Kelley, Bach, and Abel, all good judges and ſevere critics.

The common guitar uſed in England has frequently had fits of favour in this country. About 50 years ago, its vogue was ſo great among all ranks of people, as nearly to break all the harpſichord and ſpinet makers, and indeed the harpſichord maſters themſelves. All the ladies diſpoſed of their harpſichords at auctions for one-third of their price, or exchanged them for guitars; till old Kirkman, the harpſichord maker, after almoſt ruining himſelf with buying in his inſtruments, for better times, purchaſed likewiſe ſome cheap guitars and made a preſent of ſeveral to girls in milliners' ſhops, and to ballad ſingers, in the ſtreets, whom he had taught to accompany themſelves, with a few chords and triplets, which ſoon made the ladies aſhamed of their frivolous and vulgar taſte, and return to the harpſichord.

But during the guitar paroxyſm, not a ſong or ballad was printed, without its being tranſpoſed, and ſet for that inſtrument, at the bottom of the page; as in the beginning of the laſt century was done for the common flute. The old tablature, however, was thrown aſide, and the ſame notation adopted for the guitar as for other inſtruments; but confined to the key of C natural, except by Merelia, a good player on the inſtrument, and not a bad compoſer, who tuned and taught the guitar in the key of A major.

It is difficult to trace the origin of the guitar. The reſt of Europe had it from the Spaniards, to whom it was probably brought by the Moors. It is, however, the general opinion in Spain, that it is as ancient as the harp. Either through reſpect for this opinion, or from the ſweet reverie which it inſpires, being congenial with the national, tender, gallant, diſcreet, and melancholy character; whether, in ſhort, the ſilence of the beautiful nights in Spain, when the inhabitants are moſt alert and active, is moſt favourable to its mild and dulcet harmony, we know not; but it is eſtabliſhed there as a national inſtrument. It has had the ſame ſucceſs among the Portugueſe and the Italians; and ſeems to have been at all times the favourite inſtrument of warm climates: it is ſo portable, and graceful of carriage, that ſerenaders, nocturnal revellers, and day-break lovers, prefer it to all other tuneful interpreters of paſſion.

The Portugueſe having loſt a battle, 14,000 guitars were found on the field of battle. Menagiana. tom. 1.

The tone of this inſtrument is ſo ſoft and ſolemn, that the moſt profound ſilence is neceſſary for its refinements and delicacy to be enjoyed. Only the coarſer part of the inſtrument can be heard through the leaſt noiſe.

It is made to be heard alone, or with a voice. It is unfit for a concert, and has therefore given way to the lute and theorbo, as theſe have ſince done to more powerful inſtruments.

In France, ſome lovers of muſic revived, a few years ago, the paſſion for this inſtrument, which was in great vogue there in Louis XIVth's time; and was a very ſociable companion of French vaudevilles, paſtorials, and brunettes, of which, ſays M. Laborde, it augments the charms.

GUITGUIT, in *Ornithology*. See CERTHIA.

GUITRES, in *Geography*, a town of France, in the department of the Gironde, and chief place of a canton, in the diſtrict of Libourne; eight miles N. of Libourne. The place contains 933, and the canton 10,169 inhabitants, on a territory of 202½ kiliometres, in 13 communes.

GUITTONE D'AREZZO, FRA, in *Biography*, an Italian poet of the thirteenth century, was a native of the place whence he takes his name. He was a brother of the military order of the Virgin Mary, and poſſeſſed a ſufficient ſtock of piety to become the founder of a monaſtery in Florence. His poems were in great eſteem, and he is ſaid to have been the firſt who gave regularity to the Italian ſonnet. His poems are to be met with in ſeveral collections of ancient poetry. Forty of his letters were publiſhed by Bottari, at Rome, in 1745. He died in the year 1299.

GUJURAT, or GUJERAT, in *Geography*, a town of Hindooſtan, in the ſoubah of Lahore; 50 miles N. of Lahore. N. lat. 32° 37′. E. long. 73° 25′.

GUIZARRA, a town of Africa, in Barca; 20 miles E. of Augela.

GULA, in *Anatomy*, the œſophagus or gullet; that conduit by which animals take down food into the ſtomach.

GULÆ *Vaginalis*. See VAGINALIS.

GULA, in *Architecture*, the neck of the capital of a column; alſo the wavy member called cymatium or ogee. In a horizontal moulding, when the greateſt projection is the concave part, it is called a cima-recta, and when the greateſt projection is the convex part, it is called a cima-reverſa. See the articles CYMATIUM, CIMA-RECTA, CIMA-REVERSA, and OGEE.

GULAMBER, in *Geography*, a town of Curdiſtan; 30 miles N.W. of Sherezur.

GULAMERICK, a town of Curdiſtan; 60 miles S.S.W. of Van.

GULANNESS, a cape on the coaſt of Scotland, the ſoutherly point where the Frith of Forth enters the German ſea, as Fifeneſs forms the northerly. N. lat. 56° 5′. W. long. 2° 44′.

GULASISI, in *Natural Hiſtory*, a name given by the people of the Philippine iſlands to a very ſmall and very beautiful ſpecies of parrot.

GULBE, in *Architecture*, the ſame as gorge.

GULDENSTEIN, in *Geography*, a town of Denmark,

in

in the iſland of Funen.—Alſo, a town of the duchy of Holſtein; 20 miles S.S.W. of Oldeburg.

GULE *of Auguſt*, the day of St. Peter *ad vincula*, which is celebrated on the firſt of Auguſt.

It is called the gule of Auguſt, from the Latin *gula*, *a throat*, for this reaſon, that one Quirinus, a tribune, having a daughter that had a diſeaſe in her throat, went to pope Alexander, the ſixth from St. Peter, and deſired of him to ſee the chains that St. Peter was chained with under Nero, which requeſt being granted, and ſhe, kiſſing the chains, was cured of her diſeaſe: whereupon the pope inſtituted this feaſt in honour of St. Peter, and, as before, this day was termed only the calends of Auguſt; it was on this occaſion called indifferently either the day of St. Peter *ad vincula*, from what wrought the miracle; or the gule of Auguſt, from that part of the virgin whereon it was wrought.

GULES, in *Heraldry*, ſignifies the colour of red.

The word is French *gueules*, which Fa. Moued derives from the Hebrew *glud* or *guludid*, a reddiſh pellicle or ſkin appearing on a wound when it begins to heal; but F. Meneſtrier reproaches him, that there were no ſuch words in the Hebrew tongue. This, however, is not ſtrictly true: all the eaſtern languages, the Hebrew, Chaldee, Syriac, and Arabs, ſay, גלד, *gheld*, for *cutis*, *pellis*: whence the Arabic *gulud*: and in the general, the word *gules* ſignifies *red*, among moſt of the oriental nations: the Arabs and Perſians give the name to the roſe. Others, with Nicod, derive the name *gules* from *gula*, the throats of animals being generally red; or from the Latin *cuſculium*, which is the κοκκος of the Greeks, or ſcarlet grain.

The ſame colour, in the coats of noblemen, is by ſome called *ruby*, and in thoſe of ſovereign princes, *Mars*; but this is no ſtanding practice.

In engraving, gules is expreſſed by perpendicular ſtrokes drawn from the top of the eſcutcheon to the bottom; it is alſo marked with the letter G.

This colour is reputed a ſymbol of charity, valour, hardineſs, generoſity; and repreſents blood-colour, cinnabar, and true ſcarlet. It is the firſt of all colours uſed in armoury; and is of that account, that anciently it was prohibited any perſon to wear gules in his coat-armour, unleſs he were a prince, or had permiſſion from the prince.

Spelman, in his Aſpilogia, ſays, that this colour was particularly honoured by the Romans, as it had been before by the Trojans; and that they painted the bodies of their gods, and of their generals that triumphed, with vermilion. Under the conſuls, the Roman ſoldiers wore red, whence they were denominated *ruſſati*. Joan. de Bado Aureo adds, that the red dye, which the Greeks call *Phœnician*, and we *ſcarlet*, was firſt uſed by the Romans, to prevent ſeeing the blood iſſue from wounds in fight.

In effect, gules has always been eſteemed an imperial colour: the emperors were cloathed, ſhod, and had their apartments furniſhed with red; their edicts, diſpatches, ſignatures, and ſeals, were of red ink and red wax, whence the name *rubrics*.

GULF, or GULPH, in *Geography*, an arm or part of the ocean, running up within the land, and forming a capacious bay between two promontories.

The word comes from the French *golfe*, and that from the Italian *golfo*, which ſignify the ſame. Some deduce theſe farther, from the Greek κολπος; which Guichart again derives from the Hebrew גאב, *gob*: Du Cange derives them from the barbarous Latin *gulfum* or *gulfus*, which ſignify the ſame thing.

Such is the gulf of Venice, called alſo the Adriatic ſea; the gulf of Conſtantinople, called the Black ſea; the gulf of Perſia, called the Red ſea; the gulf of Lyons; the gulf of Sidra, near Barbary; the gulf of Mexico, of St. Lawrence, of California; the gulf of Bengal, and thoſe of Cochinchina and Kamtſchatka.

A gulf is ſtrictly diſtinguiſhed from a *ſea*, becauſe the latter is larger; from a *bay* or ſinus it is again diſtinguiſhed, by its being greater than the ſame.

Some will have it eſſential to a gulf, to run into the land through a ſtrait or narrow paſſage.

The ſea is always moſt dangerous near gulfs, becauſe of the currents being penned up by the ſhores.

GULF, or GULPH, in *Mining*, is one of thoſe numerous appellations in different places, for a fiſſure or *Fault*, ſee that article. Ground that is broken, ſoft and mixed, is ſaid to be *gulfy*.

GULF, or *Trough*, is applied to the ſunk pieces of ſtrata between two parallel faults, which ſometimes occur, and are called gulfs of that ſubſtance or ſtratum which happens to occupy the ſurface of the ſunk piece; or if the ſtrata are wholly ſunk, and gravel occupies the place of what would otherwiſe have been a deep chaſm or a lake, it is called a gravel gulf.

A remarkable ſhale gulf occurs in the town of Buxton in Derbyſhire, extending from the brook ſouthward, up to Dr. Buxton's houſe; theſe faults, and the great one in which they terminate, that bounds all the great Derbyſhire limeſtone tract, on the north-weſt and ſouth, clearly occaſion the hot ſprings of this place. Another remarkable ſhale gulf occurs in the limeſtone north-eaſt of Wirkſworth town, which is of conſiderable length and depreſſion, and formerly ſeems to have occaſioned hot ſprings here, before the mine-foughs entirely diverted the courſes of the ſprings in all this diſtrict. A more remarkable ſhale gulf than either of the former, occurs on the north of Dowal in Hartington, entirely ſurrounded by four lime-ſtone hills of conſiderable height, (ſee ſection in Phil. Mag. plate 2. vol. xxxi.), having ſhake-holes and ſwallows around it, which clearly point out the line of fault, which ſurrounds this piece of ſhale, with its inferior ſtrata, about a mile long and a furlong wide, and has depreſſed, or ſunk it, about 5 or 600 yards at the leaſt. Dowal is one of the moſt ſurpriſing places, perhaps, in all England.

GULF *of Florida*. See BAHAMA *Straits*.

GULF *Stream*, a remarkable current in the ocean, which runs along the coaſt, at unequal diſtances from Cape Florida to the iſle of Sables and the banks of Newfoundland, where it turns off and runs through the Weſtern iſlands; thence to the coaſt of Africa, and along that coaſt in a ſouthern direction, till it arrives at, and ſupplies the place of thoſe waters, carried by the conſtant trade winds from the coaſt of Africa towards the W., thus producing a conſtant circulating current. This ſtream is about 75 miles from the ſhores of the ſouthern ſtates, and the diſtance increaſes as you proceed northward. The breadth of it is about 40 or 50 miles, widening towards the north. Its common rapidity is three miles an hour. A north-eaſt wind narrows the ſtream, renders it more rapid, and drives it nearer the coaſt. North-weſt and weſt winds produce a contrary effect. The gulf ſtream is ſuppoſed to be occaſioned by the trade winds that are conſtantly driving the water to the weſtward, which, being compreſſed in the gulf of Mexico, finds a paſſage between Florida and the Bahama iſlands, and runs to the north-eaſt along the American coaſt. This hypotheſis is confirmed by another fact: it is ſaid, that the water in the

gulf of Mexico is many yards higher than the weſtern ſide of the continent in the Pacific ocean. It is highly probable that the ſand carried down by great rivers into bays, and the current out of theſe bays meeting with the gulf ſtream, by their eddies, have formed Nantucket ſhoals, cape Cod, George's bank, the iſland of Sable, &c. Skilful navigators, who have acquired a knowledge of the extent to which this ſtream reaches on the New England coaſt, have learnt in their voyages from Europe to New England, New York, or Pennſylvania, to paſs the banks of Newfoundland, in about 44° or 45° N. lat., to ſail thence in a courſe between the northern edge of the gulf ſtream and the ſhoals and banks of Sable iſland, George's bank, and Nantucket, by which they make better and quicker voyages to America. It is obſerved by Mr. Rennell (Phil. Tranſ. vol. lxxxiii. p. 2.) that ſome currents, after being projected into the ſea, never again approach the ſhore; but preſerve, to a very great diſtance, nearly the direction in which they were projected, as well as a conſiderable degree of their original velocity, and temperature. The gulf ſtream, he ſays, is a wonderful inſtance of this kind; which originating in a body of *pent-up* waters, in the gulf of Mexico, is diſcharged with ſuch velocity through the ſtraits of Bahama, that its motion is traceable through the Atlantic, to the banks of Newfoundland; and may poſſibly extend much farther. In a ſimilar manner, he ſays, the current of the bay of Biſcay continues its courſe, which may be about N.W. by W. from the coaſt of France, to the weſtward of Scilly and Iceland. In order to explain the manner in which waters *pent-up* may produce a current, this ingenious writer refers to an experiment of the late Mr. Smeaton. In a canal of about four miles in length, the water was kept up *four inches* higher at one end than at the other, by the mere action of the wind along the canal. The effect of a ſtrong S.W. or N.W. wind, on our own coaſts, is well known; namely, that of raiſing very high tides in the Britiſh channel, or in the Thames, and on the eaſtern coaſts, as theſe winds reſpectively blow: becauſe the water, that is accumulated, cannot eſcape quick enough, by the ſtrait of Dover, to allow of the level being preſerved. Alſo, that the Baltic is kept up *two feet* at leaſt, by a ſtrong N.W. wind of any continuance, and that the Caſpian ſea is higher by *ſeveral* feet, at either end, as a ſtrong northerly or ſoutherly wind prevails. Conſequently, as water pent up, in a ſituation from which it cannot *eſcape*, acquires a higher level, ſo, in a place where it can *eſcape*, the ſame operation produces a current; and this current will extend to a greater or leſs diſtance, according to the force with which it is ſet in motion, or, in other words, according to the height at which it is kept up by the wind. In relation to this ſubject we ſhall further obſerve, that it is perhaps on account of currents that the Red ſea is found to be about 25 feet higher than the Mediterranean; their direction may poſſibly have been ſomewhat changed in the courſe of many ages, and with it the level of the Mediterranean alſo; ſince the floor of the cathedral at Ravenna is now ſeveral feet lower with reſpect to the ſea than it is ſuppoſed to have been formerly, and ſome ſteps have been found in the rock of Malta, apparently intended for aſcending it, which are at preſent under water.

A chart of this gulf-ſtream was publiſhed by Dr. Franklin in 1768, principally from the information of capt. Folger. This was confirmed by the ingenious experiments of Dr. Blagden, publiſhed in 1781, who found that the water of the gulf ſtream was from ſix to eleven degrees warmer than the water of the ſea through which it runs; which muſt have been occaſioned by its being brought from a hotter climate. He aſcribes the origin of this current to the power of the trade-winds, which, blowing always in the ſame direction carry the waters of the Atlantic ocean to the weſtward, till they are ſtopped by the oppoſing continent on the W. of the gulf of Mexico, and are thus accumulated there, and run down the gulf of Florida. (Phil. Tranſ. vol. lxxi. p. 335.) Governor Pownal has given an elegant map of this gulf ſtream, tracing it from the gulf of Florida northward as far as cape Sable in Nova Scotia, between the Canary iſlands and Senegal, increaſing in breadth as it runs, till it occupies five or ſix degrees of latitude. The governor likewiſe aſcribes this current to the force of the trade-winds protruding the waters weſtward, till they are oppoſed by the continent, and accumulated in the gulf of Mexico. He ingeniouſly obſerves, that a great eddy muſt be produced in the Atlantic ocean between this gulf ſtream and the weſterly current produced by the tropical winds, and in this eddy are found the immenſe fields of floating vegetables, called Saragoſa weeds, and Gulf weeds, and ſome light woods, which circulate in theſe vaſt eddies, or are occaſionally driven out of them by the winds. (Hydraulic and Nautical Obſervations by governor Pownal, in 1787.) It is probable, that in proceſs of time, the narrow tract of land on the W. of the gulf of Mexico, may be worn away by this elevation of water daſhing againſt it, by which this immenſe current would ceaſe to exiſt, and a wonderful change take place in the gulf of Mexico and Weſt Indian iſlands, by the ſubſiding of the ſea, which might probably lay all thoſe iſlands into one, or join them to the continent.

Gulf, in *Rural Economy*, a term provincially applied to a mow, or bay-full in a barn.

Gulf *Stead*, the name provincially uſed to a bay or diviſion of a barn. It is ſometimes written *goafsted* and *gafſtead*.

GULFAR, in *Geography*, a town of Portugal, in the province of Beira; 13 miles N.E of Viſeu.

GULISTANI, a town of Perſian Armenia; 25 miles S.E. of Kanja.

GULKIRAS, a town of Aſiatic Turkey, in the government of Sivas; 22 miles from Amaſieh.

GULL, in *Ornithology*. See Larus.

Gull *Iſland*, in *Geography*, a ſmall iſland on the coaſt of Newfoundland, near cape St. John.—Alſo, a ſmall iſland near the coaſt of North Carolina, in Pamlico ſound. N. lat. 35° 28'. W. long. 76° 17'.

GULLABGUNGE, a town of Hindooſtan, in the circar of Bilſah; 15 miles N. of Bilſah.

GULLAPALOOR, a town of Hindooſtan, in the circar of Rajamundry; 30 miles N.E. of Rajamundry.

GULLARY, a town of Hindooſtan, in Viſiapour; 16 miles N.W. of Baddammy.

GULLET. See Œsophagus.

GULLIES, in *Geology*, is a term applied to the narrow, deep, and ſmall vallies formed or deepened by torrents of water on the higher parts of the ſkirts of mountains. (Kirwan's Geo. Eſſays, p. 181.) Sometimes ſuch are called dingles, dumbles, ravines, &c. The gullies frequently preſent very favourable opportunities for examining the ſtratification of a mountain: and after examining theſe, it will be important to examine the vallies into which the gullies empty themſelves, and to note the ſtate of rounding and mixture, which the matters diſplaced by the waters from the gullies have undergone, and the diſtances to which they have been carried downwards: much intereſting information on which ſubject, will be found in M. De Luc's Elementary Treatiſe on Geology, page 90 to 107.

GULLIES, in *Engineery*, is a name in ſome places for the iron tram-plates or rails laid for the uſe of tram-waggons.

GULLIPANAIG, in *Geography*, a town of Hindooſtan, in the Carnatic; 28 miles W.S.W. of Madura.

GULMA, a town of Morung; 85 miles E. of Amerpour.

GULNY, a town of Aſia, in the country of Caſhy; 14 miles S.E. of Caſhy.

GULO. See GLUTTON.

GULO, in *Zoology*. See URSUS *Gulo*.

GULOICK, in *Architecture*. See IMPOST.

GULT, in *Geography*, a town of Pruſſia, in the circle of Natangen; nine miles S.S.W. of Lick.

GULUBUR, a town of New Navarre; 125 miles S.S.W. of Caſa Grande.

GULUS, in *Ancient Geography*, a river of Mauritania Cæſarienſis, whoſe mouth is placed by Ptolemy in the gulf of Numidia, between thoſe of Ampſaga and Igilgili.

GULYAVAN, in *Natural Hiſtory*, a name given by the people of the Philippine iſlands to a very beautiful bird, common in that part of the world; it is of the ſize of a turtle-dove, and is very beautifully variegated with black and gold-coloured feathers. It feeds on fruits.

GULZOW, in *Geography*, a town of Hinder Pomerania; 17 miles S.E. of Cummin.

GUM, GUMMI, a mucilaginous or reſinous juice, exuding through the pores of certain plants or trees, chiefly of tropical climates, by natural clefts or artificial inciſions, and hardening on the ſurface, by means of the ſun and air, into tenacious tranſparent maſſes of an irregular form. They are commonly diſtinguiſhed into *gum mucilage* and *gum reſin*.

GUM *Mucilage* is characteriſed by the following eſſential chemical properties: it is inſipid, diſſoluble in water, forming with it a viſcid tranſparent fluid; but not diſſoluble in alcohol, not coagulated by heat, nor cryſtallizable; but after the aqueous ſolution has been evaporated to dryneſs, it is again ſoluble in water without ſeeming to have undergone any material change. When kept for ſome time it is ſlowly altered, and becomes mouldy and ſomewhat ſour. By being heated to ignition it ſwells and ſoftens, aſſumes a yellow, brown, and black colour, exhales a denſe vapour of a pungent acid ſmell, and burns with much flame: at length a ſoft ſpungy coal remains.

The pureſt of the gum-mucilages is gum arabic or Senegal: and ſimilar to this, but inferior in quality, is the amber-coloured gum that oozes from cracks in plum, peach, apricot, pear, cherry, and other fruit trees; and which may alſo be obtained from ſeveral plants, ſuch as the lichens, the leaves of the comfrey, and mullein, the root of the hare-bell, and the whole plant of the marſh-mallow, by ſimple decoction and evaporation to dryneſs. In order to obtain gum from the lichen, a well known moſs, that grows abundantly on foreſt and fruit trees, and in the north of Europe and America, growing to the length of a foot or more, gives food to deer and other animals, lord Dundonald gives the following directions. (Phil. Mag. vol. x.) Below the ſkin of the lichen is a green reſinous ſubſtance, and the reſidue of the plant conſiſts chiefly of gum and of fibrous matter, which is not acted upon by water. In order to ſeparate the ſkin and reſinous matter, the plant muſt be ſcalded two or three times with boiling water, which cauſes the ſkin to crack, ſwell, and peel off. It is then to be put into a boiler, containing about three quarts of water for every pound of the plant, and about half an ounce of potaſh or ſoda, which aſſiſts the extraction; and the boiling ſhould be continued till the liquor acquires a conſiderable degree of gummy conſiſtence. The liquor is next to be ſtrained from the plant, and freſh water added to the ſame material, for the purpoſe of further exhauſting the gum. The ſeveral liquors, after having been allowed to ſettle, and the drugs being removed, are to be boiled down in a regulated heat to the conſiſtence requiſite for uſe, but not further, leſt it ſhould burn and become coloured. Two or three boilings are neceſſary entirely to exhauſt the lichen of its mucilage. Another ſpecies of native mucilage is *gum* TRAGACANTH; which ſee. See MUCILAGE, and *gum* ARABIC.

GUM *Reſins* are the juices which flow from many kinds of trees, and which become concrete by the evaporation of their fineſt fluid parts, nearly in their natural ſtate, and retaining for a conſiderable time the ſenſible properties of ſmell and taſte. They combine, as their name imports, the diſtinguiſhing properties of *gum* and *reſin*; and therefore gum-reſins are not perfectly ſoluble either by water, by oils, or by ſpirit of wine ſingly: a kind of ſolution is effected by the aid of trituration, *e gr.* in water; but the reſinous part remains ſuſpended, and forms a kind of emulſion, being divided but not diſſolved, whilſt the gummy part is entirely ſoluble in water, and forms a mucilage with it. The reſinous part gives them the property of burning with much flame, melting in drops by the heat; and the gummy part, their partial ſolubility in water. For the complete ſolution of a gum-reſin, the reſinous part muſt be ſeparated from the gummy part, by applying alternately a ſpirituous and watery menſtruum. The clear liquor remaining, when the gum-reſin has ſubſided, always retains ſome of the taſte and ſmell of the ſubſtance employed. All gum-reſins are combined of ſubſtances not mutually ſoluble by each other, and therefore the compound bodies reſulting from their mixture muſt be opaque: all thoſe concrete juices that are not evidently tranſparent, may, from hence, be reaſonably ſuſpected, to be of a gummy reſinous nature; ſuch are *myrrh*, *galbanum*, *olibanum*, *ammoniacum*, *ſagapenum*, *opopanax*, *aſſa-fœtida*, &c. See RESINS. Some of the gum reſinous juices are mixed with a kind of extract (ſee EXTRACT), or a coloured and bitter ſubſtance, ſoluble in water and alcohol; and alſo tan (ſee TAN) is very commonly united to them. It is obſerved, upon the whole, that the term gum-reſin is more properly a pharmaceutical than a chemical diſtinction.

Gum-reſins, for medical purpoſes, ſhould be rendered pure, by boiling them in water until they ſoften, and then paſſed through a hempen cloth; afterwards let them be ſet by, that the reſinous part may ſubſide. Pour off and evaporate the ſupernatant ſolution by a water-bath, and towards the end of the inſpiſſation mix intimately the reſinous part with the gummy. Thoſe which melt eaſily may be purified by putting them into an ox-bladder, and holding them in boiling water, until they become ſoft enough to be ſeparated from their impurities by preſſure through a hempen cloth.

Dr. Pringle, in his Obſervations on the Diſeaſes of the Army, tells us that gums are all powerful antiſeptics.

Theophraſtus ſpeaks of a way of multiplying plants, performed *per lachrymas*, by means of the gum or reſin; but Agricola takes this to be only practicable where there are ſeeds accidentially fallen into the gum.

GUM *Ammoniac*. See AMMONIAC.

GUM *Anime*. See ANIME.

GUM *Apples*, in Languedoc, and ſome other parts of France. The juice of apples will ſometimes exſudate through their rind, and congeal all about them in form of a clear white gum, hard like ice, becauſe of its being ſoon dried in the ſun into a thin cake. The people call ſuch an apple *pomme gelée*, or a *frozen apple*. It is very common to ſee apples covered in part with this gum in ſeveral ſpecks; but

it is more rare to meet with them wholly ſo. The gum is inſipid to the taſte.

We have one plant cultivated in ſome gardens, which yields in the heat of ſummer ſuch another white, icy, and taſteleſs gum. This is the common rhubarb, of the ſtalks of the leaves of which tarts are made. The ribs of the larger leaves of this plant, in June and July, are covered with large tranſparent drops of this gum, and an ounce of it may be ſometimes collected from a ſingle plant. Philoſ. Tranſ. N° 224.

The common plums and ſloes in our hedges alſo afford the ſame clear and taſteleſs white gum. If they are wounded on purpoſe for it, they uſually throw more or leſs of it out at the wound; but this is after ſome time, and is not in ſo large a quantity as what they naturally throw out. The common laurel alſo affords a little tranſparent, white, and taſteleſs gum of no ill effect, though its leaves are poiſonous. And it ſeems, upon the whole, that this clear juice is not peculiar to apples, or to two or three plants only; but that a great number, even moſt of them, do contain it, if we knew by what means to get it from them.

GUM *Scammony*. See SCAMMONY.

GUM *Seneca*, or *Senega*, is the gum ordinarily ſold by the druggiſts for gum Arabic, which it reſembles very nearly both as to form and virtue. It is either white, bordering on yellow, or of a deep amber colour, tranſparent, &c. It oozes out of a prickly ſhrub common enough in Africa, and of the ſame genus with that which affords the gum Arabic. The greater part of this gum is in larger and darker-coloured maſſes than the Arabic, and not ſmooth like it, but tough on the outſide. This is ſuppoſed to be the ſtrongeſt and moſt ſubſtantial, and the Arabic the pureſt and fineſt.

The gum Senegal is chiefly employed by the calico-printers, and in other buſineſſes where gums are made uſe of. A proper vehicle for water-colours in painting may be formed by mixing a third or fourth part of the gum Senegal with gum Arabic, for the former dries more ſlowly than the latter, which is ſubject to crack and ſeparate from the cartoon or grounds, on which the colour is laid with it, without ſome ſuch mixture.

The gum is brought to us from Senegal, whence its name. See GUM ARABIC.

GUM *Tragacanth*. See TRAGACANTH.

GUM *Water*. See WATER.

GUM, in *Gardening*, a vegetable diſeaſe incident to fruit-trees of the ſtone kind, diſtinguiſhed by a morbid exudation of gummy matter from the wounded alburnum, or inner bark. It is ſuppoſed by Mr. Forſyth to ariſe from injudicious pruning, from bruiſes, or any injuries received in the wood or bark, which may happen from ſtrokes of the hammer in nailing, from pinching the ſhoots by nailing the ſhreds too tight, or by driving the nails too cloſe to the branches. And it may be occaſioned by leaving the foot-ſtalks of the fruit, or by pruning in ſummer and cutting the ſhoots to ſhort ſtumps, and by injuries ſuſtained by a careleſs application of ladders in nailing and gathering the fruit, &c., but it originates more particularly where large limbs have been lopped or broken off. It may be known before the gum itſelf makes its appearance by the bark at firſt becoming of a browniſh colour, and gradually growing darker, till at laſt the gum begins to ooze out like little bliſters. As ſoon as any of theſe marks are met with, the infected part ſhould be cut out with a ſharp inſtrument, and the compoſition and powder, which he has recommended, applied immediately. In doing this, the gum ſhould be cut out perfectly clean. It may be ſeen oozing out from between the wood and bark, and muſt be followed till the white clean bark and wood is arrived at. And afterwards, if any gum ſhould make its appearance it muſt be ſcraped off; which is beſt done when it is moiſtened with rain, as it can then be ſcraped off eaſily without hurting the bark of the tree. This buſineſs muſt be performed without delay, otherwiſe the diſeaſe will advance with rapidity, and greatly injure the trees or other plants which it may affect.

The ſame author alſo reccommends, that when trees are hollow they ſhould be examined carefully, to ſee whether any grubs have entered the bark and wood, which is known by their perforating the bark; and that where there are any, they ſhould be carefully cut out before the compoſition is applied to the tree.

It has been ſuggeſted by the author of the "Philoſophy of Gardening," that this exudation may, perhaps, be prevented from continuing to flow, by binding on the part, previouſly ſmoothed by a knife, thin ſheet lead, ſuch as tea is wrapped in, in ſuch a manner as to prevent the exudation and the conſequent exhauſtion of the tree. A piece of ſponge, ſoft leather, or Indian rubber, ſhould be bound on under it, till the part is healed. A ſtrong ſolution of green vitriol in water is likewiſe ſuppoſed capable of being uſeful, by being applied to the extremities of the exuding veſſels, and thus ſtimulating them into contraction, and by that means preventing the further diſcharge of this ſubſtance from the tree.

The nice application of a piece of freſh bark, taken from a ſimilar tree of inferior value, kept on by the elaſtic preſſure of a liſt bandage, is alſo ſuggeſted as worthy of being made a trial of in the ſame intention, where it can be done with propriety.

GUMS, *Diſeaſes of*. The gums, in the natural healthy ſtate, are not accounted very ſenſible parts; they may be divided with a lancet without any great deal of pain being occaſioned; and the preſſure of hard ſubſtances againſt them in maſtication is not productive of any injury. When inflamed, however, in conſequence of decayed teeth, a cold, or any other cauſe, they are affected with extreme ſenſibility, ſwell in a conſiderable degree, and cannot be touched, or preſſed, in the ſlighteſt manner, without much ſuffering being excited. We ſee, in the practice of ſurgery, numerous other inſtances in which parts, almoſt deſtitute of ſenſibility in the healthy ſtate, become inſupportably tender when affected

affected with inflammation. The ligaments are naturally almoſt devoid of ſenſation; but in ſeveral diſeaſes of the joints, they are even much more painful than ſome other inflamed parts, which, when ſound, poſſeſs a vaſt deal of ſenſibility. In infancy, during the progreſs of dentition, ſhould there be inflammation of the gums, the ſlighteſt preſſure produces ſo much ſuffering, that children will even refuſe the breaſt, on account of the pain reſulting from the unavoidable preſſure of the nipple. On the contrary, when there is no inflammation, the gums are ſo inſenſible, that young children are pleaſed with ſucking or biting a hard cruſt. In old age, when all the teeth are loſt, the hardneſs and inſenſibility of the gums qualify them for performing the office of the teeth, and biting and bruiſing the food without pain.

Some of the diſeaſes of the gums originate from thoſe of the teeth, while others ariſe in an independent manner, quite unconnected with a diſeaſe of any other neighbouring part,

Of Gum-Boils, or Gum-Biles.—It is noticed by Mr. Hunter, that although ſuppuration cannot eaſily take place, within the cavity of a tooth, yet, it often happens, that the inflammation which extends beyond it is ſo great as to produce ſuppuration in the jaw, at the bottom of the ſocket, where the diſeaſed tooth is, ſo as to form a ſmall abſceſs there, commonly called a gum-bile.

This inflammation is often very conſiderable, eſpecially when the firſt ſuppuration takes place, being frequently more diffuſed than inflammations in other parts, and affecting the whole face.

As in all other abſceſſes the matter makes its own way outward, and ſince it cannot be evacuated through the tooth, it deſtroys the alveolar proceſſes, and tumefies the gum, generally on the forepart, either pointing directly at the root of the tooth, or ſeparating the gum from it. The matter is uſually diſcharged in one of theſe ways, and ſeldom on the inſide of the gum, though the latter occurrence is ſometimes obſerved.

Gum-biles moſtly proceed from an inflammation and ſwelling of the fang of a tooth, while the body of the ſame continues ſound. Sometimes they originate from a diſeaſe in the ſocket, or jaw, which has no connection with the tooth, and only affects it ſecondarily. Upon drawing ſuch teeth, ſays Mr. Hunter, they are generally found diſeaſed at or near the point, being there very rough and irregular, like ulcerating bones. The laſt kind of gum-biles may ariſe altogether from ſuch a cauſe, the appearance on the fang of the tooth being only an effect.

The ſame ſurgeon has explained, that theſe abſceſſes, whether ariſing from the teeth, or the ſockets, always deſtroy the alveolar proceſſes on that ſide where the matter is diſcharged, on which account the tooth is rendered more or leſs looſe. This event may be ſeen in many ſkulls, and alſo frequently in the living ſubject; for, when the alveolar proceſs is deſtroyed, on the outſide of the tooth, if the latter part be moved, the motion may be obſerved under the gum all along the fang.

When theſe abſceſſes have burſt through the gums they often cloſe up, and put on the appearance of being healed; but ſuch as diſcharge themſelves, between the gums and teeth, can never heal up, becauſe the gum cannot unite to the tooth. At certain periods, however, the diſcharge from them diminiſhes, owing to a ſubſidence of the ſuppuration; but, either expoſure to cold, or ſome other accidental cauſe, occaſioning a freſh inflammation, an increaſe of the ſuppuration is the conſequence, and either the old orifice in the gum becomes opened again, or the diſcharge by the ſide of the tooth is augmented. In the latter caſe, Mr. Hunter believes, that the affection is leſs ſevere than in the former, in which freſh ulceration is required for the paſſage of the matter.

Thus a gum-bile goes on for years, healing and opening alternately; the effect of which is, that the alveolar proceſſes are at length abſorbed, and the tooth gets looſer and looſer, till it either drops out, or is extracted.

Moſt probably, in all ſuch caſes, ſays Mr. Hunter, the communication between the cavity of the tooth and the jaw is cut off; yet it keeps in part its lateral attachments, eſpecially when the gum graſps the tooth; but theſe attachments are leſs when the matter paſſes between the gum and the tooth, though ſome of them are ſtill retained, particularly on the ſide oppoſite to the paſſage for the matter.

Gum-biles are eaſily known. Thoſe which open through the gum may be diſtinguiſhed by a ſmall riſing between the arch of the gum and the attachment of the lip. Upon preſſing the gum at the ſide of this point, ſome matter will commonly be obſerved oozing out at the eminence. This eminence ſeldom ſubſides entirely; for even when there is no diſcharge, and the opening is healed over, a ſmall riſing may ſtill be perceived, which ſhews that the gum-bile has been there.

Such gum-biles as diſcharge themſelves between the gum and the tooth, are always diſcovered by preſſing the gum, whereby the matter is forced out, and is ſeen lying in the angle between the gum and the tooth.

Mr. Hunter alſo acquaints us that theſe abſceſſes happen much more frequently in the upper jaw than in the lower, and more frequently to the cuſpidati inciſores and bicuſpides in that jaw than to the molares; ſeldom to the fore-teeth in the lower jaw.

Gum-biles, being generally the conſequence of decayed teeth, are more frequently met with in young and middle-aged perſons than in old; but, according to Mr. Hunter, they are moſt common to the ſhedding teeth, which are moſt liable to decay. A fungus will ſometimes ſhoot out of the orifice of a gum-bile, in conſequence of a luxuriant diſpoſition to form granulations on the inſide of the abſceſs, and the opening being backward to heal. The ſame thing frequently happens in iſſues, where the parts have a diſpoſition to granulate, but have not the power of healing, on account of an extraneous body being kept there. In the preſent caſe the tooth acts as an extraneous body; and, by the ſecretion of matter, the abſceſs is prevented from healing. There is no difference in the treatment of gum-biles, whether they ariſe from a diſeaſed tooth, or a diſeaſe in the ſocket.

When an abſceſs forms round the root of a tooth, the tooth, by loſing its connection with the other parts, loſes every power of union, as it is not endowed with the power of granulating. Hence it becomes an extraneous body, or at leaſt acts here as one, and that of the worſt kind, which, ſays Mr. Hunter, it is not in the power of any operation in the machine to get rid of. This is not the caſe with any other part of the body; for, when any other part becomes dead, the machine has the power of ſeparating it from the living by a proceſs called ſloughing, or exfoliation. (See EXFOLIATION and GANGRENE.) The mortified portion is thrown off, and a cure is effected. But, in the caſe of gum-biles, they can only be cured by the extraction of the tooth; and as this is the laſt reſource, Mr. Hunter obſerves, that every thing ſhould be done to make the parts as eaſy under the diſeaſe as poſſible, ſo that this operation may be poſtponed.

When the abſceſs has burſt through the gum, Mr. Hunter adviſes us to keep the opening from cloſing, with a view of preventing future gatherings. He recommends enlarging the opening, and keeping it enlarged till all the inſide of the

the abſceſs is ſkinned over, or the aperture in the gum loſes the diſpoſition to cloſe up. This will in a great meaſure prevent any future formation of matter, or at leaſt whatever is formed will find a ready outlet, ſo that no accumulation can happen. The end of the fang, indeed, will be expoſed; but, under ſuch circumſtances, it will not be in a worſe ſituation than when ſoaked in matter.

Mr. Hunter next remarks, that one method of doing this is to open the gum-biles by a crucial inciſion, the full width of the abſceſs, and fill it with lint, which ſhould be dipped in lime water, or a diluted ſolution of lunar cauſtic, made by diſſolving one drachm of the cauſtic in two ounces of diſtilled water; and the wound ſhould be dreſſed very frequently, as it is with difficulty that the dreſſing can be kept in. If this is not ſufficient to keep the wound open, it may be touched with the lunar cauſtic, ſo as to produce a ſlough; and the application may be repeated, if found neceſſary. Some difficulty is experienced in keeping on the dreſſings; but conſtant attention will make up for the inconvenience of ſituation.

Mr. Hunter alſo ſpeaks in favour of touching the ſurface of the abſceſs with the lapis ſepticus, and keeping the lip from coming into contact with the part for one minute, within which ſpace of time the cauſtic will penetrate to the bottom.

The ſurface of the bile ſhould be wiped as dry as poſſible, that the cauſtic may not do miſchief by ſpreading.

It has been a practice to extract the tooth, then file off any diſeaſed part of it, and immediately replace it. This method has often failed, in conſequence of the tooth being introduced into a diſeaſed jaw; but, occaſionally, it has ſucceeded.

When a gum-bile is formed on a back tooth, the treatment, according to Mr. Hunter, need not be ſo nice as when the abſceſs is ſituated upon any of the fore-teeth, becauſe appearances are then of leſs conſequence. Therefore the gum may be ſlit down upon the fang through its whole length, from the opening of the gum-bile to its edge, which proceeding will prevent any future union, while the healing of all the cavity of the abſceſs will prevent any future collection of matter. The wound afterwards reſembles the hare-lip. Hence this practice is not adviſable when the place of the cut would be much in view, as when the abſceſs is ſituated upon any of the fore-teeth. In theſe caſes, when the granulations protrude from the ſmall opening, a cure may be effected in the manner above-mentioned, or the granulations may be cut off with a knife or lancet. However, in general, a permanent cure cannot be thus effected, and the granulations riſe up again. It has been common in theſe caſes to ſlit the gum; but, ſays Mr. Hunter, it is a bad method whenever the defect is in ſight.—Hunter on the Teeth, part 2. ſect. 4.

Excreſcences from the Gum.—In conſequence of bad teeth excreſcences alſo ariſe from the gum, near, or in contact with the teeth which are diſeaſed. In general, ſuch growths may be eaſily removed with a knife, or any other cutting inſtrument which may be found moſt convenient. They will often riſe, in a day or two after the operation, as high as ever; but this newly generated matter generally ſoon dies, and the diſeaſe terminates well. They frequently have ſo much of a cancerous appearance as to deter ſurgeons from meddling with them; but Mr. Hunter believed, that, when they ariſe at once from the gum, and appear to be the only diſeaſed part, they have no malignant diſpoſition. However, this great ſurgeon had ſeen them with very broad baſes when the whole could not be removed, and yet no bad conſequences reſulted from the partial removal of them. In a few years they often riſe again, by which means a great deal of trouble is occaſioned.

After the extirpation it is often neceſſary to apply the actual cautery, in order to ſtop the bleeding; for, as Mr. Hunter obſerves, arteries, going to increaſed parts, are themſelves increaſed, and alſo become diſeaſed, and have not the contractile power of a ſound artery. (See Hiſtory of the Teeth, p. 170, third edit.) Averſe, however, as we are to the uſe of the actual cautery, we ſhould be reluctant to employ it without firſt being aſſured that the preſſure of a doſſil of lint, dipped in ſome ſtrong ſtyptic application, would not anſwer.

Treatment of the Gums in Dentition.—The firſt ſet of teeth, in making their way through the gums, give pain, and produce many other ſymptoms which often prove fatal to children. Mr. Hunter thought that theſe complaints were occaſioned in the following manner: The teeth, when they begin to preſs againſt the gums, irritate them, and commonly give pain. The gums are then affected with heat, ſwelling, redneſs, and other ſymptoms of inflammation. The gum is not cut through by ſimple or mechanical preſſure; but the irritation and conſequent inflammation produce a thinning or waſting of the gum at this part; for, ſays Mr. Hunter, it often happens, that when an extraneous, or a dead ſubſtance, is contained in the body, it produces a deſtruction of the part between it and that part of the ſkin which is neareſt it, and ſeldom of the other parts, excepting thoſe between it and the ſurface of a cavity opening externally, and that by no means ſo frequently. In thoſe caſes there is an abſorption of the ſolids, which are deſtroyed, and not a melting down, or ſolution of them into pus. The teeth are to be looked upon as extraneous bodies, with reſpect to the gum; and, as ſuch, they irritate the inſide of that part in the ſame manner as the pus of an abſceſs, an exfoliating piece of bone, or any other extraneous body, and therefore produce the ſame ſymptoms, excepting only the formation of matter. If, then, theſe ſymptoms attend the cutting of the teeth, there can be no doubt of the propriety of opening the way for them; nor is it ever, as far as Mr. Hunter's experience went, attended with any dangerous conſequence. Hunter on the Teeth, p. 80.

Dentition being a change which begins at a very early age, its ſymptoms are more diffuſed, more general, and more uncertain than thoſe of any diſorder of full-grown people, and they put on the appearance of a great variety of maladies; but theſe ſymptoms, ſays Mr. Hunter, become leſs various and leſs hazardous as the child advances in years. Hence the double teeth of the child, and particularly the ſecond ſet of teeth, or thoſe of the adult, are uſually cut without producing much diſturbance.

Theſe ſymptoms are ſo various in different children, and often in the ſame child, that it is difficult to conceive them to be from the ſame origin, and the varieties ſeem to baffle inveſtigation.

Both local and conſtitutional complaints are excited. Of the firſt kind may be reckoned the pain, which the child expreſſes when it is reſtleſs, uneaſy, rubs its gums, and puts every thing into its mouth. Inflammation, heat, and ſwelling of the gums, and an increaſed flow of the ſaliva, alſo happen.

The conſtitutional complaints are, fever and univerſal convulſion.

What Mr. Hunter termed the *partial* or *local* conſequential ſymptoms, are the moſt various and complicated. Theſe are diarrhœa, coſtiveneſs, loſs of appetite, eruptions on the ſkin, eſpecially on the face and ſcalp, cough, ſhortneſs of breath, with a kind of convulſed reſpiration, ſimilar to what

is obſerved in the hooping cough, ſpaſms of particular parts, either by intervals or continued, an increaſed ſecretion of urine, and ſometimes a diminution of that ſecretion, a diſcharge of matter from the penis, with difficulty and pain in making water, imitating exactly a violent gonorrhœa.

The lymphatic glands of the neck are apt to ſwell; and when the child has a tendency to ſcrofula, the irritation will promote the origin of this laſt diſtemper.

With regard to the cure of the diſeaſes ariſing from dentition, it can only be temporary and local, even when directed to the real ſeat of the diſorder; and certainly, ſays Mr. Hunter, every method of cure which is not ſo directed, muſt prove ineffectual, as it can only operate by deſtroying the effect. Opiates, indeed, will in ſome degree take off the irritation, by deſtroying the ſenſibility of the part. But ſurely it would be better to remove the cauſe at once, than to endeavour from time to time to remove or palliate the effect. Mr. Hunter obſerves, that, when the ſympathy is partial, and not in a vital part, it would be better to allow it to continue than cure it, becauſe it might by ſuch means be rendered univerſal. For inſtance, ſays he, if it is a diarrhœa, the beſt way is to allow it to go on, or at leaſt only correct it if too violent, which is often the caſe.

Sometimes the ſtomach and inteſtines ſympathize ſo much as almoſt to threaten death, the ſmall quantity of nouriſhment which the ſtomach is capable of receiving being hurried off by the bowels.

As far as Mr. Hunter's experience taught him, cutting the gum down to the teeth appears to be the only method of cure. It acts either by taking off the tenſion upon the gum, ariſing from the growth of the tooth, or by preventing the ulceration, which muſt otherwiſe take place.

It often happens, particularly when the operation is performed early, that the gum will unite over the teeth, in which caſe the ſame ſymptoms will be produced, and they muſt be removed by the ſame method.

Mr. Hunter informs us, that he had performed the operation above ten times upon the ſame teeth, where the diſeaſe had recurred as often, and every time with the abſolute removal of the ſymptoms.

He notices the aſſertion that to cut the gum once will be ſufficient, not only to remove the preſent, but to prevent any future bad ſymptoms from the ſame cauſe. This he maintains is contradictory to experiment and the known laws of the animal economy; for frequently the gum, from its thickneſs over the tooth, or other cauſes, muſt neceſſarily heal up again, and the relapſe is as unavoidable as the original diſeaſe.

He adverts to the vulgar objection to the practice, that if the gum is lanced ſo early as to admit of re-union, the cicatrized part will be harder than the original gum; and, therefore, the teeth will find more difficulty in paſſing, and give more pain. He affirms that this is contrary to facts; for we find that all parts which have been the ſeat either of wounds or ſores, are always more ready to give way to preſſure, or any other diſeaſe, which attacks either the part itſelf or the conſtitution. Therefore each operation tends to make the paſſing of the teeth more eaſy.

The fore-teeth may be at firſt obſerved not upon the edge of the gum, but upon the fore-part, making riſings there, which appear whiter than the other parts, and the gums ſeem broader than uſual. At this period the inciſions muſt be made pretty deep, till the tooth be felt with the inſtrument, otherwiſe little effect will be produced by the operation; and this is the general rule with reſpect to the depth of the inciſion in all caſes.

When the grinders ſhoot into the gum they flatten its edge, and make it broad. They are more eaſily hit than the fore-teeth.

The operation ſhould not be done with a fine-pointed inſtrument, ſuch as a common lancet, becauſe, moſt probably, the point will be broken off againſt the tooth. A common lancet with its point rounded, is a very good inſtrument; but an inſtrument like a fleam would be the moſt convenient.

There is no need of any great delicacy in the operation, the gums being very inſenſible parts; and to cut through the whole gum down to the teeth, with certainty, when they are pretty deep, requires ſome force.

The gums will bleed a little, which may be of ſervice in taking off the inflammation. Mr. Hunter never ſaw a caſe in which the bleeding proved either inconvenient or dangerous. If it ſhould ever be troubleſome, there would be no great difficulty in ſtopping it. No application to the cut is neceſſary. See Hunter on the Teeth, p. 233—243.

Scurvy of the Gums.—The name of this very common diſeaſe is derived from its being attended with appearances ſimilar to thoſe which accompany the ſea-ſcurvy. The gums ſwell, become extremely tender, and bleed upon every occaſion; they are redder than natural, and their veſſels are exceedingly turgid.

When the gums firſt begin to be tender, it is firſt obſervable upon their edges. The common ſmooth ſkin of the gum is not continued to its very edge, but it becomes in that ſituation a little rough like a border, and ſomewhat thickened. The part of the gum between two teeth ſwells, and often puſhes out like luxuriant fleſh, which is frequently very tender.

Mr. Hunter alſo acquaints us that the inflammation is often carried ſo far as to make the gums ulcerate, ſo that in many caſes they have a common ulcer upon them, and ſome of the teeth are denuded by the ulceration. This is often on one part only, often only on one jaw; while, in ſome caſes, it is all along the gums of both jaws.

It frequently happens in this caſe that the alveolar proceſs diſappears by abſorption, in which event there is always a very conſiderable diſcharge of matter from the inſide of the gum and alveolar proceſs, flowing out in the direction of the tooth.

In many of theſe caſes, ſays Mr. Hunter, we find that, while the gums are ulcerating in one part, they are ſwelling and becoming ſpongy in another, and hanging looſe upon the teeth; and this often takes place when there is no where any ulceration. Hunter on the Teeth, p. 184—186.

At length the teeth become looſe, and in a few years drop out, one after the other, at ſhort intervals, until the perſon is rendered toothleſs. It is from this complaint that many perſons loſe their teeth at a very early period of life. Indeed moſt individuals are more or leſs ſubject to it, as the gums, in ſome part or another, although there be no ſymptoms of the diſeaſe, are likely to become preternaturally red, enlarged, and tender. Therefore, whenever a tendency to this diſeaſe is obſerved, great care ſhould be taken to apply ſuch means as will arreſt its progreſs. At its commencement, ſays Mr. Fox, it is very manageable, and may always be relieved by puncturing with the point of a lancet thoſe parts which appear unnaturally red or diſtended. The loſs of blood affords immediate relief; and whenever the ſlighteſt ſoreneſs, or an increaſed fulneſs of the gums, is perceived, the above plan of ſcarifying the veſſels will be found highly beneficial. Suppoſe the diſeaſe to have proceeded to that ſtage in which the gums become ſpongy or looſe in texture, the lancet

should be then used with greater freedom. Essential service is always derived from the loss of blood. In some cases leeches, which draw away a larger quantity of blood, are attended with the best effects. Frequent recourse should be had to this treatment, which may be accompanied with the use of astringent lotions, such as the infusion of roses with the tincture of myrrh, decoction of bark, solutions of alum, arquebusade water, &c. In these cases great benefit is derived from the use of sea-water, and, Mr. Fox observes, that he always recommends it when it can be procured, directing it to be used warm if the gums be tender. Whenever the gums are disposed to inflame in consequence of this disease, much good may be expected from the free use of a tooth-brush. At first the gums are apt to bleed a little, by which the same benefit is obtained as from the lancet. By degrees the gums become more firm, and at length a hard brush may be used, without causing any loss of blood, or giving the slightest pain.

When the gums are exceedingly tender, and have any tendency to ulceration, Mr. Fox recommends washing the mouth very frequently with barley water, sweetened with honey. In two or three days, if the soreness is diminished, the lancet is to be cautiously used with the diluted tincture of myrrh as a wash.

When this treatment fails in making the edges of the gums heal, and they hang loosely about the necks of the teeth, Mr. Fox observes, that much good will be derived from the use of a solution of the argentum nitratum. He says, that if the disease be only partial, the caustic should be applied with a camel's hair pencil dipped in the solution. This remedy is described as communicating a new action to the gums, and they generally get well in a short time. Indeed, whenever the gums are very full, and discharge a good deal of offensive matter, washing the mouth with a solution of lunar caustic is, according to Mr. Fox, a very excellent means of rendering the mouth sweet and comfortable.

This remedy, when applied to the sore edges of the gums with a hair pencil, may be used as strong as in the proportion of a dram of the argentum, to an ounce of distilled water; but, if the mouth is to be rinsed with it, not more than one grain of the caustic should be put to two ounces of water, lest, by being too strong and getting into the throat, it should occasion an unpleasant nausea.

Persons, who are often troubled with inflammation of the gums, ought to have them scarified whenever they become painful, or are more turgid than usual. By the loss of a small quantity of blood, the affection is immediately relieved, and kept from committing the ravages which have been related.

Mr. Fox adds, that in scarifying the gums, the lancet should be applied longitudinally to those parts, which are situated between the teeth, because, if the gums are cut where they cover the fangs, they will shrink in healing, and leave the necks of the teeth exposed. On the other hand, if the gums are lanced in the angles between the teeth, they will be drawn tighter in healing, and the teeth be eventually strengthened. Fox on the Diseases of the Teeth, p. 72—76.

Mr. Hunter suspected, that what is commonly meant by the scurvy of the gums might proceed from various causes, as he had often seen the appearances attendant on the disorder, in children of a manifestly scrofulous habit, as well as in adults and other persons, who were in all other respects perfectly healthy. He thought that the practice of cutting away a part of the gums, when they were enlarged and apparently redundant, was not the best method. We do not, in this way, remove an adventitious substance, as when we destroy luxuriant granulations on a sore; but a part of the gum itself is taken away. In a similar manner, a part enlarged by inflammation might be reduced to its natural size, a plan which would certainly not be advisable. The same eminent writer believed, that whatever good has resulted from such practice has been owing to the bleeding; and that scarifying the gums answers the same purpose.

When there are reasons for supposing the scurvy of the gums to arise from any peculiarity of constitution, we are recommended to try to correct such peculiarity. When the habit is scorbutic, the original distemper must be removed; when it is scrofulous, Mr. Hunter thinks that scarifications may do harm, by wounding the parts. In the last kind of case, he speaks in favour of sea-bathing, and washing the mouth frequently with sea-water. Page 186—187. edit. 3.

Callous Thickenings of the Gums.—The gums are subject to some diseases, which have no connection with the alveoli and teeth. A very common one is a hard, callous thickening of a part of the gum, similar to an excrescence. It frequently has a cancerous appearance, which deters the surgeon from interfering, though generally without reason. It often admits of being removed by the knife; but not always. Mr. Hunter states, that the bleeding which follows is generally so considerable, that it is frequently necessary to apply the actual cautery.

Excrescences of this kind sometimes grow again, which subjects the patient to the same operation. Mr. Hunter has known of their being extracted as often as six times; but in such cases he suspected that they really had a cancerous disposition. Hunter on the Teeth, p. 188. edit. 3.

What more appertains to the foregoing subject, will be found in another part of this work. See Teeth, *Diseases of.*

GUMACA, in *Geography*, a town on the N.E. coast of the island of Luçon. N. lat. 14° 21′. E. long. 122° 27′.

GUMARA, in *Ancient Geography*, an island of the Indian sea, placed by Ptolemy near the island of Taprobana.

GUMBINNEN, in *Geography*, a town of Prussian Lithuania, containing two churches, 200 houses, and 3000 inhabitants, with some manufactures of cloth; 65 miles E. of Konigsberg.

GUMBORITZ, a town of Russia, in the government of Olonetz; 16 miles S. of Olonetz.

GUMIPOLLAM, a town of Hindoostan, in Mysore; 53 miles N.N.E. of Bangalore. N. lat. 14° 48′. E. long. 78° 5′.

GUMISH-KANEH, a town of Turkish Armenia; 33 miles S.S.E. of Trebisond.

GUMMA, a town of Japan, in the island of Niphon; 56 miles N. of Jeddo.

Gumma, a term in *Surgery*, denoting a swelling arising from the substance of a bone, and having such a degree of softness, as makes it in some measure yield to the finger. The appellation is said to be derived from the resemblance of the tumour to gum in consistence. As these swellings increase in hardness, they are progressively called tophi, nodi, and exostoses. Gummata are sometimes symptoms of the venereal disease; but sometimes they exist, without our being able to assign any reasonable cause for their origin. See Exostoses, Nodes, Lues Venerea, &c.

GUMMI Olivæ, *olive gum*, in the *Materia Medica of the Ancients*. We meet with this name given to a drug they sometimes used in coughs and diseases of the lungs. This was the concreted juice or exudation of the olive-tree, called by the Greeks δακρυα Ελαιας, and by the Latins *gummi oliva*.

GUMMURGE, in *Geography*, a town of Hindooſtan, in the circar of Chandail; 45 miles W.N.W. of Saipour.

GUMRA, a town of Africa, in Sahara, ſurrounded with earthen walls; 150 miles S. of Algiers.

GUMSOOR, a town of Hindooſtan, in the country of Oriſſa; 80 miles S.W. of Cattack. N. lat. 10 45'. E. long. 84 49'.

GUN, a fire-arm or weapon of offence, which forcibly diſcharges a ball, ſhot, or other offenſive matter, through a cylindrical barrel, by means of gunpowder.

Gun is a general name, under which are included divers, or even moſt ſpecies of fire-arms. They may be divided into *great* and *ſmall*. See ARMS.

For the hiſtory and invention of guns, ſee CANNON and GUNPOWDER.

For the uſe and application of guns, ſee GUNNERY and PROJECTILES.

GUN, *Bed of*. See BED.

GUN, *Boring of*. See *Boring of* CANNON and FOUNDERY.

GUN, *Carriage of*. See CARRIAGE.

GUN, *Charging of*. See CHARGE and CANNON.

GUN, *Chaſe*. See CHASE *guns*.

GUN, *Evening*, is generally a twelve pounder, that is fired every night about ſun-ſet, and every morning at ſun-riſe, to give notice to the drums and trumpets of the army to beat and ſound the retreat and the reveille.

GUNS, *Exerciſe of*, denotes the method of laying, loading, and firing the guns, at various diſtances from the butt or mark: Mr. Robins recommends a more extenſive exerciſe than that of firing with a conſtant charge at two or three marks, placed at known and invariable diſtances, in which the ranges, penetrations, and deflections of pieces, fired with all neceſſary diverſity of charge, elevation, and diſtance, ſhould be examined, and the reſult compared with the new principles explained under the article GUNNERY, &c. See EXERCISE.

GUN *Flint*, in *Technological Mineralogy*. The mode of manufacturing gun-flints, as we have obſerved in the article FLINT, has for a long time been involved in fable and myſtery: indeed, even in the Mémoires de l'Académie de France, we are told, "that there is never a deficiency of flints in thoſe countries where they have once been found; that, as ſoon as a quarry appears exhauſted it is ſhut up; and that when after a certain number of years it is re-opened, the flints are found there under the ſame circumſtances as before." The ſame erroneous idea is repeated in the French Encyclopédie, and other works; and it was not till lately that we have been made fully acquainted (by Hacquet of Vienna and by Dolomieu) with the ſimple manner of manufacturing gun-flints in Gallicia and France, where they conſtitute an important article of commerce. The latter of the above naturaliſts has given an account of it in the Mem. de l'Inſtitut National des Sciences (Claſſe Mathématique et Phyſique, t. 3. an. ix); the former in a monograph on this ſubject, written in the German language.

In France, the beſt flints are found in the neighbourhood of St. Aignan, in the department of the Loir-et-Cher, and in that of the Indre, and the departments that occupy the vallies of Seine-et-Marne: they occur as horizontal banks in fletz-limeſtone, particularly chalk, and alſo in marle. Among twenty of ſuch beds, or layers, ſituated one above the other at the diſtance of about twenty feet, there is generally only one, very ſeldom two, that furniſh good gun-flints: all thoſe of a good quality are coated with a white earthy rind. (See FLINT.) On the banks of the Cher, the flints are excavated by means of ſhafts of forty to fifty feet in depth, from whence levels or horizontal galleries are carried into the only good ſtratum which is known in that diſtrict; but on the banks of the Seine, in the hillocks of Rocheguyon, where the cliffs of chalks preſent broken precipices, the beds of flint are laid open to view: one of theſe beds, which contains the good ſort, is at about ſix fathoms diſtance from the upper ſurface of the great maſs of chalk.

The characters by which the good flints are diſtinguiſhed from thoſe leſs fit for being manufactured are the following: Their ſurface is rather convex, approaching to globular; thoſe that are amorphous, or of a very irregular form, ſuch as knobbed, branched, &c. are generally full of imperfections. Good flint nodules ſeldom exceed the weight of twenty pounds; nor are thoſe that weigh leſs than one or even two pounds conſidered as being of a good quality. Internally they ſhould appear unctuous and rather ſhining, with a grain too fine to be perceptible to the eye. The colour may vary from honey-yellow to blackiſh brown; but the tint ſhould be uniform in the ſame nodule. Their tranſparency ſhould be ſufficient to admit letters to be diſtinguiſhed through a piece of the ſtone of a quarter of a line thick, laid cloſe upon the paper. Their fracture ſhould be perfectly ſmooth and equal throughout, and the fragments ſlightly conchoidal. The laſt of theſe properties is the moſt eſſential, ſince on it depends the facility with which the nodule is divided into gun-flints. All flints that prove deficient in any one of the above characters, either naturally or by a long expoſure to the air, are called *intractable*, and rejected by the workmen.

The tools made uſe of by the *caillouteurs* (a name given to the makers of gun-flints in France) are four in number: 1. A hammer or mace of iron with a ſquare head (*Pl.* II. *Geology*, *fig.* 1.), the weight of which does not exceed two pounds; (but it may be of half that weight only,) with a handle of ſeven or eight inches long. This tool is not made of ſteel, for an exceſs of hardneſs would render the ſtrokes too hard or dry (as the phraſe is), and would ſhatter the nodules irregularly, inſtead of breaking them by a clear fracture.

2. A hammer with two points (*fig.* 2.) This is made of good ſteel, well hardened; its weight does not exceed ſixteen ounces; indeed it may weigh ten ounces only. Its handle is ſeven inches long, paſſing through it in ſuch a manner that the points of the hammer are nearer the hand of the workman, than the centre of gravity of the maſs. The form and ſize of the hammers of different workmen vary a little; but this diſpoſition of the points is common to them all, and is of conſequence to the force and certainty of the blow.

3. The disk-hammer, or roller, a ſmall tool, called in French *roulette*, which repreſents a ſolid wheel, or ſegment of a cylinder, two inches and four lines in diameter (*fig.* 3.): its weight does not exceed twelve ounces. It is made of ſteel not hardened, and is fixed on a handle ſix inches in length, which paſſes through a ſquare hole in the centre.

4. A chiſſel tapering and bevilled at both extremities (*fig.* 4.), ſeven or eight inches long, and two inches wide, made of ſteel not hardened: this is ſet on a block of wood, which, at the ſame time, ſerves as a bench for the workmen.

To theſe four tools we may add a file, for the purpoſe of reſtoring the edge of the chiſſel from time to time.

After having ſelected a good maſs of flint, the following four operations are performed by the workman.

1. *To break the block.*—The workman, being ſeated on the ground, places the nodule of flint on his left thigh, and applies ſlight ſtrokes with the ſquare hammer, to divide it

into ſmaller pieces of about a pound and a half each, with broad ſurfaces, and almoſt even fracture. The ſtrokes ſhould be moderate, leſt the maſs crack and ſplit in the wrong direction.

2. *To cleave or chip the flint.*—The principal operation is to ſplit the flint well, or to chip off ſcales of the length, thickneſs, and ſhape adapted, to be afterwards faſhioned into gun-flints. In this part the greateſt degree of addreſs and certainty of manipulation are required. The fracture of the flint is not confined to any particular direction; it may be chipped in all parts with equal facility.

The workman holds the piece of flint in his left hand, not ſupported, and ſtrikes with the pointed hammer, No. 2, on the edges of the great planes produced by the firſt breaking, by which means the white coating of the flint is removed in the form of ſmall ſcales, and the maſs of the flint itſelf laid bare in the manner repreſented, *fig.* 5; after which he continues to chip off ſimilar ſcaly portions from the pure maſs of the flint. Theſe ſcaly portions are nearly one inch and a half wide, two inches and a half long; and their thickneſs, in the middle, is of about two lines. They are ſlightly convex below, and conſequently leave in the part of the flint from which they were ſeparated a ſpace ſlightly concave, longitudinally bordered by two, rather projecting, ſtraight lines or ridges, *fig.* 6. Theſe ridges, produced by the ſeparation of the firſt ſcales, muſt naturally conſtitute nearly the middle of the ſubſequent pieces; and ſuch ſcales alone as have their ridges thus placed in the middle are fit to be made into gun-flints. In this manner the workman continues to ſplit or chip the maſs of flint in various directions, until the defects uſually found in the interior render it impoſſible to make the fractures required, or until the piece is reduced too much to receive the ſmall blows by which the flint is divided.

3. *To faſhion the gun-flint.*—Five different parts may be diſtinguiſhed in a gun-flint. 1. The ſloping facet, or bevil part, which is impelled againſt the hammer of the lock of the gun: it is called by the French *mèche*. Its width ſhould be from two to three-twelfths of an inch: if it were broader it would be too liable to break; and if more obtuſe, the ſcintillation would be leſs briſk. 2dly. The ſides, or lateral edges, which are always rather irregular. 3dly. The back, or the part oppoſite the tapering edge: this is the thickeſt part of the flint. The French call it *talon*. 4thly. The under ſurface, which is uninterrupted and rather convex. And, 5thly. The upper face, a ſmall ſquare facet between the tapering edge and the back, which receives the upper claw of the cock; it is ſlightly concave. The French term for it is *aſſis*.

In order to faſhion the flint, thoſe ſcales are ſelected that have at leaſt one of the above-mentioned longitudinal ridges: the workman fixes on one of the two tapering borders to form the ſtriking edge; after which, the two ſides of the ſtone that are to form the lateral edges, as well as the part which is to form the back, are ſucceſſively placed on the edge of the chiſſel in ſuch a manner, that the convex ſurface of the flint, which reſts on the fore-finger of his left hand, is turned towards that tool. He then, with the roulette, applies ſome ſlight ſtrokes to the flint juſt oppoſite the edge of the chiſſel underneath; by which means the flint breaks exactly along the edge of the chiſſel.

4. The finiſhing operation is the trimming, or the proceſs of giving the flint a ſmooth and equal edge; this is done by turning the ſtone, and placing the edge of its tapering end on the chiſſel, in which ſituation it is completed by five or ſix ſlight ſtrokes with the roulette. This is termed *raffiler* by the French workmen.

The whole operation of making a gun-flint is performed in leſs than one minute. A good workman is able to manufacture a thouſand good chips or ſcales a day (if the flint nodules be of a good quality); and in the ſame manner he can faſhion 500 gun-flints in a day; ſo that in the ſpace of three days he is able to cleave and finiſh a thouſand gun-flints without farther aſſiſtance.

This work leaves a great quantity of refuſe, for ſcarcely more than half of the ſcales are good, and nearly half the maſs in the beſt flints is incapable of being chipped out, ſo that it ſeldom happens that the largeſt nodules will furniſh more than fifty gun-flints. Such ſcales as have a cruſt, or are too thick to be made into gun-flints, are uſed for the more common culinary purpoſe of ſtriking a light. Thoſe that are ſold at Paris are brought from the banks of the Seine, and are generally of a brown colour.

The gun-flints are ſorted out according to their perfection, and the uſe to which they are to be applied. They are claſſed into extra and common flints; flints for piſtols, muſkets, and fowling-pieces.

Gun, *Pointing of a*, ſo as to ſtrike diſtant objects, depends on two things, *viz.* 1. Tracing on the outſide of the piece a viſual line parallel to the axis, which is called *diſparting*, and is performed by taking half the difference of the diameters of the muzzle and baſe-ring, and ſetting it perpendicularly on the muzzle-ring directly over the centre; for then a line, which paſſes from that point in the baſe-ring, which is directly over the centre of the piece, to the extremity of the diſtance thus placed on the muzzle-ring, will, when the piece is truly bored, be parallel to its axis: ſee Diſpart and *Line of* Direction. 2. The other operation is the determining of the allowance to be made in diſtant ſhot for the incurvation of the flight of the bullet: this is greater or leſs (*cæteris paribus*) according to the different charges of powder made uſe of. Mr. Robins has determined, that ſuch a charge as produces a velocity between 1100 and 1200 feet in a ſecond, is in many caſes the moſt eligible: ſuppoſing, therefore, that the piece is loaded with ſuch a charge; in this caſe, if the ſhot were not retarded by the reſiſtance of the air, the range correſponding to one degree of this piece might be reckoned 450 yards, to two degrees 900, to three degrees 1350, &c. ſince, independently of the air's reſiſtance, the ranges at different elevations would be nearly in proportion to theſe angles, at leaſt as far as eight or ten degrees. But the reſiſtance of the air will occaſion a conſiderable alteration; becauſe, by diminiſhing the velocity of the bullet, it will render its track more incurvated than it would otherwiſe be, and diminiſh its range; and the ſmaller the ſhot, the greater would be the diminution. The following table will ſerve to ſhew the angles of elevation correſponding in different pieces to different diſtances, and will ſave the labour of computation.

Actual Range in Yards.	Angle of Elevation.									
	24 lb		12 lb		9 lb		6 lb		3 lb	
1400	4	12	4	30	4	45	5	0	5	57
1200	3	26	3	40	3	50	4	0	4	30
1000	2	45	2	54	3	0	3	7	3	30
800	2	6	2	10	2	13	2	20	2	30
600	1	30	1	32	1	34	1	36	1	44
500	1	13	1	15	1	17	1	19	1	22
400		58		58½		59	1	0¼	1	3
300		43		43		43		44		43
200		27¾		28¼		23½		28¾		29½
100		14		14		14¼		14½		15

By this table, when the diſtance of the object is known, the angle, by which the axis of the piece ought to be elevated above the viſual line, will be readily determined; and when this angle is known, the piece may be directed or pointed, by meaſuring the length of it from the middle of the baſe-ring to the middle of the muzzle-ring, and computing the tangent of the given angle of elevation to that radius, which may be done either by a table of tangents, or by ſuppoſing that to a radius of one foot, 21 of an inch is the tangent of a degree. Let C H B D (*Plate* I. *Gunnery*, *fig.* 1.) be the given piece, A B its axis, D E half the difference between the diameter of the muzzle-ring and baſe-ring, and C E the line of *diſpart*; then make C G equal to the tangent of elevation juſt found, and the line G E will be the proper line for pointing of the piece. In practice it will be ſufficient to erect only one perpendicular: *e. gr.* if G C exceed D E, their difference erected on the baſe-ring will, with the muzzle-ring at D, give the line of direction; but if D E exceed G C, the ſame difference erected on the muzzle-ring will, with the baſe-ring at C, give the direction of the piece. In diſtances leſs than 500 yards, it will be ſufficient to allow one-fourth of a degree for the inclination correſponding to every hundred yards, without having recourſe to the table. Mr. Robins obſerves, that the charge of powder producing the velocity above ſtated as the moſt eligible, is from one-ſixth to one-fourth of the weight of the bullet in powder; the different goodneſs of powder, and the difference in the length of pieces producing that diverſity. Robins's Tracts, vol. i. p. 312, &c.

The common mechanical method of directing cannon to a given object, is to find the centre-line, or two points, one at the breech and the other at the muzzle, by a ſmall inſtrument called the perpendicular, and then applying the two fore fingers to the baſe centre to look behind them, till the muzzle centre be made to cut the centre of the object; then the piece is properly directed: and having found the neceſſary elevation, place the centre of the quadrant in the bore, and raiſe or depreſs the piece till the plummet cuts the required elevation.

GUN, *Proving of a.* See PROVING.

GUN, *Rifle.* See RIFLE.

GUNS, *Small*, include fire-locks, muſkets, muſketoons, carabines, blunderbuſſes, fowling-pieces, &c.

Piſtols and mortars are almoſt the only kinds of regular weapons, charged with gunpowder, that are excepted from the denomination of guns.

Since the article FOWLING-*piece* was written, we have been able to collect ſome further information. We did not give any deſcription of the breechings of guns, which is of conſiderable importance in their ſhooting. Almoſt every maker has a breech of his own contrivance, though they are all, on the ſame principle, only alterations, without improvements, taken from the original patent, which was the late Mr. Henry Nock's. See *Plate* I. *Gunnery*, *fig.* 2.

a a, the ſcrew to fit the barrel.

c, the centre-hole or chamber.

d, the ante-chamber.

F, a ſcrew adapted to reach the ante-chamber, the only uſe of which is to enable the workman to cut the ante-chamber.

B B B B, the outſide circumference, which may be made to any convenient form.

The advantages ariſing from this breeching are, that the ſhot are thrown in a more perfect direction and with greater velocity: that the barrel is much leſs ſubject to grow partially foul: that guns on this principle, after being fired 20 or 30 times, loſe very little of their force, in compariſon with thoſe of the old conſtruction; that they are ſafer, and go off more inſtantaneouſly; alſo, they inflame the whole of the powder.

Gun-makers only diſtinguiſh two kinds of defects in their barrels; the grey, and the crack or flaw: the grey is that which we, under the article FOWLING-*piece*, deſcribed as the flaw. The crack is of very little conſequence if near the muzzle of the barrel, but if at the breech end, though it may be mended, it is never done by reſpectable makers. The method of diſcovering it is by forcing it with water. The beſt barrels are never poliſhed inſide, as it is impoſſible to make a true cylinder with oil and emery, they are only fine draw bored. We have alſo, under the article before alluded to, ſaid that twiſted barrels throw their balls or ſhot with more accuracy than common ones; but here we beg leave to correct ourſelves, as that entirely depends on the boring and filing; the advantages of twiſted barrels are ſuperior ſtrength, elaſticity, and elegance.

After the barrels are bored true inſide, two perfectly cylindrical mandrils are introduced, one at each end; they are then put in a lathe, and the outſides turned to their proper ſubſtance, and conſequently muſt be of an uniform thickneſs of metal all round; but this is only done with town-made guns. Though it is known ſome makers bend the muzzles of guns, intended to kill at long diſtances, a little upwards, yet it is *by no means* to be recommended, as a barrel ſhould be as ſtraight as it is poſſible to make it. By frequent trials with long and ſhort guns, the latter are generally found to excel the former, if both guns are loaded with the ſame charge of powder and ſhot. For legal reſtrictions with regard to the uſe of guns, ſee the article GAME.

GUNS, *Great*, are called by the general name *cannon*, and make what we alſo call *ordnance* or *artillery*. See CANNON.

GUN, *Great*, at Dover caſtle, is a large braſs gun 24 feet long without, and 22 feet in the bore, beautifully adorned with flowers and emblematical figures in relievo, and ſeveral inſcriptions. This curious gun, vulgarly called queen Elizabeth's pocket piſtol, was a preſent from the emperor Charles V. to Henry VIII. while they were engaged together in a war with France. The charge of this gun is 15 pounds of powder, and it is ſaid to carry a ball ſeven or eight miles.

GUN is alſo a name given by the miners to an inſtrument uſed in cleaving rocks with gunpowder. It is an iron cylinder of an inch and quarter thick, and about ſix inches long, and having a flat ſide to receive the ſide of a wedge, and a hole drilled through it to communicate with the inſide of the hole in the rock. The hole is made of about eight inches deep, and in the bottom of it are put about two or three ounces of gunpowder; then this gun is driven forcibly in, ſo as to fill up the hole, and the wedge is driven in on its flat ſide to ſecure it. The priming at the hole is then fired by a train, and the orifice being ſo well ſtopped by this gun, the force of the powder is determined to the circumjacent parts of the rock which it ſplits. See MINE.

GUN-*room*, in a *Ship*, is the apartment on the after end of the lower or gun-deck, where the maſter-gunner and his crew rendezvous, get ready their cartridges, &c. and do all things belonging to their buſineſs. In ſmall ſhips of war, it is uſed by the lieutenants as a dining-room, &c.

GUNAISKOG, in *Geography*, a town of Sweden, in Warmeland; 34 miles N.W. of Carlſtadt.

GUNDANILLA, a town on the S. coaſt of the iſland of Porto Rico.

GUNDAVEE, a town of Guzerat, on a river which runs

runs into the gulf of Cambay. The chief article of its trade is teak wood; 25 miles S. of Surat.

GUNDAVOW, a town of Guzerat, on the coaſt; 45 miles S.W. of Noanagur.

GUNDELFINGEN, a town of Bavaria, in the principality of Neuburg, ſituated on the Brenz, near the Danube; 19 miles N.E. of Ulm. N. lat. 48° 32'. E. long. 10° 19'.

GUNDELIA, in *Botany*, ſo named by Tournefort, in honour of his companion and friend Mr. Andrew Gundelſcheimer, its diſcoverer, on the mountains of Armenia, during their journey. Tournef. Voy. v. 2 108. Cor. 51. t. 486. Linn. Gen. 453. Schreb. 593. Willd. Sp. Pl. v. 3 2402. Mart. Mill. Dict. v. 2 Juſſ. 175. Lamarck Illuſtr. t. 720. Gærtn. t. 163—Claſs and order, *Syngeneſia Polygamia-ſegregata.* Nat. Ord. *Compoſitæ*, Linn. *Cinarocephalæ*, Juſſ.

Gen. Ch. *Common Calyx* ſcarcely any, except the leaves ſurrounding the compound receptacle. *Cor.* compound, tubular, uniform, the florets five, equal. Petal of each ſimple, club-ſhaped; its limb ſwelling, five-cleft, erect. *Stam.* Filaments five, capillary, very ſhort; anthers united into a long cylinder. *Piſt.* Germen ovate, immerſed in the receptacle, inferior, crowned with minute ſcales; ſtyle thread-ſhaped, longer than the corolla; ſtigmas two, revolute, but in the lateral florets ſimple. *Peric.* none, the ſeeds being altogether hidden in the receptacle. *Seeds* ſolitary, roundiſh, pointed, crowned with an obſolete border; the lateral ones abortive. *Common receptacle* conical, entirely covered with the partial ones, ſeparated from each other by three-pointed ſcales. *Partial receptacle* inverſely conical, obtuſe, quadrangular, truncated, with five little hollows, one of them in the centre, the others in the circumference, to receive the five florets.

Eſſ. Ch. Partial calyx none. Five hollows in the partial receptacle for five florets. Corolla tubular. Four of the florets male. Common receptacle ſcaly. Seed-crown a ſlight border.

1. G. *Tournefortii*. Linn. Sp. Pl. 1315. Mill. Ic. t. 287. Tourn. Voy. v. 2. t. 108. (Silybum Dioſcoridis; Rauw. It. t. 74.)—Native of dry ſtony places in Armenia, Syria, and near Aleppo, flowering in June. It was formerly in our gardens, introduced by Tournefort, but periſhed in the hard winter of 1739. The French have ſince recovered it from the Levant, and we have ſeen one plant alive at Paris. The habit is that of a thiſtle, or eryngo. *Root* perennial. *Stem* a foot high, branched, leafy, round, ſmooth. *Leaves* large, ſeſſile, ſlightly decurrent, pinnatifid, acute, with numerous irregular ſpinous teeth; their ſurfaces bright or glaucous green, with a purpliſh rib, and downy veins. Heads of *flowers* purple, terminal, ſeſſile, encompaſſed with a few ſmaller leaves, and ſometimes a little cottony.

Tournefort calls this one of the moſt handſome plants of the Levant, "and becauſe," ſays he, "Mr. Gundelſcheimer firſt diſcovered it, we agreed that it ought, out of gratitude, to bear his name. Unhappily we had nothing but water to honour this ceremony, but this was the more ſuitable and welcome, as the plant grows only in dry ſtony places. The needle of the Pacha ſtuck up at the ſame time, which we took for a good omen; nevertheleſs, we had no ſmall trouble to hit upon a Latin name appropriate to that of our worthy friend. It was at length concluded that the plant ſhould be called *Gundelia*." *Tourn. Voy.*

GUNDELL, in *Geography*, a town of Guzerat; 30 miles E.N.E. of Junagur.

GUNDELSHEIM, a town of Germany, in the circle of Swabia, on the Neckar; 30 miles E. of Heidelberg.

GUNDEWA, a town of Hindooſtan, in Bundelcund; 12 miles S.E. of Chatterpour.

GUNDIAW, a town of Hindooſtan, in the country of Tatta; 32 miles S.S.E. of Tatta.

GUNDIGUI., a town of Hindooſtan, in the circar of Ellore; 60 miles N.E. of Ellore.

GUNDILIPALLY, a town of Hindooſtan, in Myſore; 50 miles S. of Seringapatam. N. lat. 11° 44'. E. long. 76 45'.

GUNDLING, Nicholas Jerom, in *Biography*, was born at a town near Nuremberg, where his father was miniſter. He ſtudied firſt at Aldorf under John Fabricius, and afterwards at Jena and Leipſic. He was intended for theological purſuits, which in 1698 he changed for the ſtudy of the law; in this he graduated at Halle in 1703. He ſucceeded there to the profeſſorſhip of eloquence and natural law, and was made counſellor to the conſiſtory of the duchy of Magdeburg, and afterwards privy counſellor: and laſtly rector of the univerſity of Halle. He died in 1729, leaving behind him many works which were at that time in conſiderable eſtimation: of theſe we may mention his "New Dialogues;" "Plan of a Courſe of Literary Hiſtory;" "Hiſtoria Philoſophiæ Moralis;" "Otia, or a Collection of Diſcourſes on Phyſical, Moral, Political, and Hiſtorical Topics," in three vols. 8vo. &c.

GUNDOOR, in *Geography*, a town of Hindooſtan, in the Carnatic; 18 miles S. of Nellore.—Alſo, a town of Hindooſtan, in the circar of Condapilly; 7 miles N.W. of Maſulipatam.

GUNDOROESKAIA, a town of Ruſſia, in the country of the Coſſacks, on the Donetz; 112 miles N. of Azof.

GUNDUCK, a river of Aſia, in the country of Napaul, which runs into the Ganges, oppoſite to Patna.

GUNGADI, a town of Africa, in Kijaaga, on the Senegal; 15 miles E. of Joa.

GUNGANAGURRY, a town of Hindooſtan, in Myſore; 8 miles S.S.E. of Kiſtngheri.

GUNGANAR, a town of Hindooſtan, in Canara; 25 miles S.S.E. of Onore.

GUNGAVERA, a town of Hindooſtan, in Myſore; 20 miles E. of Rydroog.

GUNJEW, a town of Hindooſtan, in Boggilcund; 20 miles N.E. of Rewah.

GUNJOORYA, a town of Bengal; 13 miles N. of Noony.

GUNKI, a town of Japan, in the iſland of Niphon; 105 miles N.E. of Jeddo.

GUNNA, a town of Sweden, in the province of Helſingland; 40 miles N.W. of Hudwickſwal.—Alſo, one of the ſmaller Scots Hebrides. N. lat. 56 35'. W. long. 6 41'.

GUNNARSKEG, a town of Sweden, in the province of Warmeland; 40 miles N.W. of Carlſtadt.

GUNNEL *of a Ship*. See Gun-*wale*.

GUNNELLUS, in *Ichthyology*. See Butter-*fiſh*.

GUNNER, John Ernest, in *Biography*, was born at Chriſtiana, in Norway, in the year 1718. He received the elementary parts of his education under private tutors, and when he was eleven years of age he was ſent to the public ſchool of Chriſtiana. Here he remained till 1737, and then proceeded to Copenhagen, where he purſued his ſtudies with ſo much ſucceſs, as to make a diſtinguiſhed figure among his fellow-ſtudents. In 1742 he repaired to the univerſity of Halle, where he ſtudied theology, philoſophy, and mathematics, under very able profeſſors, then reſident at that ſeminary. In 1754 he was invited to be extraordinary profeſſor of theology

logy at Copenhagen, preacher at Herlufsholm, and lecturer in theology and the Hebrew language in the public ſchool of that place. Shortly after this, he was ordained prieſt at Copenhagen, and in 1758 was appointed by his majeſty Frederic V. biſhop of Drontheim. He was the founder of the royal Norwegian ſociety at Drontheim, of which he was elected vice-preſident, and in the Tranſactions of which he publiſhed ſeveral curious and uſeful papers. He was a zealous ſtudent in botany, and ſo highly eſteemed by Linnæus, that he gave the name of *Gunnera* (which ſee) to a plant in his ſyſtem. He was enrolled among the members of the academies of Stockholm, Copenhagen, and other learned ſocieties. His papers in the firſt three volumes of the Tranſactions of the ſociety of Drontheim, relate chiefly to ſubjects in natural hiſtory. In 1766, he publiſhed "Flora Norvegica," part I. containing 314 ſpecies of plants, with ſome new fuci. To each are added the medical and aſtronomical uſes. See the next article.

GUNNERA, in *Botany*, ſo named by Linnæus in compliment to Dr. John Erneſt Gunner, biſhop of Drontheim, in Norway, the learned and laborious author of the *Flora Norvegica*, in two parts, folio, with twelve plates, publiſhed at Drontheim and Copenhagen, in 1766 and 1772. The number of ſpecies it contains is 1118. The author died in 1773, aged 55.—Linn. Mant. 16. Schreb. 607. Willd. Sp. Pl. v. 4. 148. Vahl. Enum. v. 1. 308. Mart. Mill. Dict. v. 2. Juſſ. 405. Lamarck. Illuſtr. t. 801. (Miſandra; Juſſ. 405.)—Claſs and order, *Gynandria Diandria*, Linn. *Diœcia Digynia*, Vahl. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juſſ.

Gen. Ch. *Cal.* Catkin whorled, its ſcales of one leaf, ſingle-flowered, briſtle-ſhaped, the length of the flowers, permanent. Perianth none, except the double-toothed cruſt of the ſeed. *Cor.* none. *Stam.* Filaments two, very ſhort, oppoſite, ſtanding on the ſides of the germen, on the outſide of its teeth; anthers oblong. *Piſt.* Germen ovate, with two teeth at the top; ſtyles two, awl-ſhaped, ſhort, hairy, between the teeth of the germen; ſtigmas ſimple. *Peric.* none. *Seed* one, ovate, coated with the perianth-like cruſt. *Linn.*

Eſſ. Ch. Calyx of two teeth, ſuperior. Corolla none. Seed with a fleſhy coat, crowned by the calyx.

Obſ. Linnæus ſubſequently ſuſpected his *G. perpenſa*, the only ſpecies known to him, to be monoecious, which often appears to be the caſe, and *G. plicata*, the *Miſandra* of Juſſieu, is even dioecious. Nevertheleſs, this genus is beſt placed in *Diandria Digynia*, as having both organs generally in the ſame flower. With *Gynandria* it does not ſeem well to accord. We ſhould rather, conſidering its affinities, preſume it to have a real inferior calyx, which in the female flower is beyond the pulpy coat of the ſeed, and that there is ſome miſtake as to the ſtamens ſtanding on the outſide of the teeth, when the flowers have both organs together. The flowers of all the ſpecies require to be examined and compared, in a living ſtate, by ſome good theoretical botaniſt. The terms within ſeems have greatly miſapplied.

1. G. *perpenſa*. Linn. Mant. 121. Thunb. Cap. v. 1. 113. (Perpenſum blitiſperum; Burm. Prod. Cap. 26. Lutea africanum, caſtiæ paluſtris folio, caule nudo cubitali, ſpicam pedalem et amplius ſuſtinente; Pluk. Phyt. t. 68. f. 2.)—Leaves kidney-ſhaped, waved, toothed, finely downy, ſhorter than the fruit-bearing ſtalk. All the ſtalks ſpiny.—Found about the margins of rivers at the Cape of Good Hope, flowering from September to December. *Root* perennial, fleſhy, ſomewhat creeping, with long downy fibres. *Leaves* radical, on long downy ſtalks, various in ſize, but uſually a ſpan wide, kidney-ſhaped, waved, toothed, or ſharply crenate, marked with numerous branching radiating ribs, cut away to the two main ſide-ribs at the baſe with a curved ſinus, finely downy on both ſides, paler and rather harſh to the touch beneath. *Flower-ſtalk* radical, compreſſed, naked, but downy in the lower part, a foot or eighteen inches high, bearing a compound bunch of innumerable ſmall greeniſh *flowers*, accompanied by linear *bracteas*.

2. G. *ſcabra*. Ruiz and Pavon. Fl. Peruv. v. 1. 29. t. 44. f. *a*. (G. chilenſis; Lamarck. Dict. v. 3. 61. Illuſtr. t. 801. f. 1. Panke anapodophylli folio; Feuill. Voy. v. 2. 741. t. 30.) Leaves palmate, ſerrated, very harſh, taller than the fruit-bearing ſtalk. All the ſtalks prickly.—Native of watery marſhy places in Chili and Peru, communicated by the late Abbé Cavanilles. Much larger than the preceding, and diſtinguiſhed by its lobed *leaves*, which are extremely rough on the upper ſide with minute callous points, as well as beſprinkled on both ſides with ſhort hairs. The *ſtalks*, both of the *leaves* and *flowers*, are beſet with ſcattered prominent prickles, and the latter are much the loweſt. The *bunch* of flowers is a ſpan long, very denſe and thickly branched. Feuillée ſays this plant is of a cooling quality, and that a decoction of its leaves is taken for that purpoſe in hot weather, and the ſtalks of the leaves are peeled and eaten. He found their flavour ſweetiſh and agreeable. The root is uſed for dyeing black, and for tanning, which proves its aſtringent quality.

3. G. *plicata*. Vahl. Enum. v. 1. 309. Willd. n. 2. (G. magellanica; Lamarck. Dict. v. 3. 61. Illuſtr. t. 801. f. 2. Miſandra; Herb. Commerſ. Juſſ. 405.)—Leaves kidney-ſhaped, crenate, plaited, ſmooth and naked, taller than the fruit-bearing ſtalk. Flowers dioecious.—Gathered by Commerſon in the ſtraits of Magellan. Mr. Menzies brought it from Staten Land, near Cape Horn. Much ſmaller than either of the foregoing. The *root* is creeping, with long, thick, ſimple, downy fibres. *Leaves* an inch or two wide, on hairy ſtalks, bluntly crenate, ſcarcely waved, many-ribbed, plaited, very ſmooth, except a few occaſional tawny briſtles on the ribs beneath. *Male flowers* in a branched looſe bunch, on a ſolitary ſlender hairy ſtalk, taller than the leaves; *female* ones on a ſeparate plant, in a denſe, ovate, nearly ſeſſile *thyrſus*, accompanied by broad membranous bracteas, and much ſhorter than the leaves. *Stigmas* very long, taper, downy, permanent. *Fruit* globoſe, red.

GUNNERS, officers of the Tower and other garriſons, whoſe buſineſs it is to manage and look after the ordnance mounted on the lines and batteries, which are all fixed and ready with cartouches and ball, for ſervice, on the ſhorteſt warning.

They carry a field-ſtaff, and a large powder horn in a ſtring over the left ſhoulder; in which equipage they march by the guns.

GUNNER, in the *Artillery*, is the ſecond rank of private men in the royal regiment of artillery.

GUNNER *of a ſhip of war*, is an officer appointed to take charge of the artillery and ammunition aboard; to obſerve that the former are kept in order, and fitted with tackle and other furniture, and to teach the ſailors the exerciſe of the cannon: he is aſſiſted by a mate, &c.

GUNNER *of England, Maſter*, is an officer appointed to teach and inſtruct all ſuch as deſire to learn the art of gunnery, and to adminiſter to every ſcholar an oath; which, beſide the duty of allegiance, obliges him not to ſerve any foreign prince or ſtate without leave; nor to teach the art of gunnery to any but ſuch as have taken the ſaid oath; and

and to certify to the maſter of the ordnance the ſufficiency of any perſon recommended to be one of his majeſty's gunners.

The gunner, ſir J. Moore obſerves, ſhould know his pieces and their names, which are taken from the height of the bore, the names of the ſeveral parts of a piece of ordnance, how to tertiate his gun, and how to diſpart it, &c.

GUNNER'S *Level.* See LEVEL.

GUNNERY, the art of ſhooting with guns and mortars, *i. e.* of charging, directing, and exploding thoſe fire-arms to the beſt advantage.

Gunnery is ſometimes conſidered as a part of the military art, and ſometimes as a part of pyrotechny.

To the art of gunnery belongs the knowledge of the force and effect of gunpowder, the dimenſions of pieces, and the proportions of the powder and ball they carry, with the methods of managing, charging, pointing, ſpunging, &c.

Some parts of gunnery are brought under mathematical conſideration, which, among mathematicians, are called abſolutely by the name gunnery; *viz.* the method of elevating or raiſing the piece to any given angle, and of computing its range; or of raiſing or directing it ſo, as it may hit a mark or object propoſed.

The inſtruments chiefly uſed in this part of gunnery are the callipers or gunners' compaſſes, quadrant, and level; the methods of applying which, ſee under thoſe articles; and for the particular principles and laws of gunnery, ſee PROJECTILE.

With regard to the hiſtory of this part of mixed mathematical ſcience we may obſerve, that long before the invention of gunnery, properly ſo called, the art of artillery was in actual practice; for one of the kings of Judah, 800 years before the Chriſtian era, erected, on the towers and bulwarks of Jeruſalem, engines of war, for ſhooting arrows and great ſtones for the defence of that city. 2 Chron. xxvi. 15.

Such machines were afterwards known to the Greeks and Romans under the names *balliſta*, *catapulta*, &c. which produced effects, by means of the action of a ſpring of a ſtrongly twiſted cordage formed of tough and elaſtic animal ſubſtances, no leſs terrible than the cannon and mortars of the moderns. Theſe warlike inſtruments continued in uſe, not only during the time of the Roman empire, but to the twelfth and thirteenth centuries; nor is it probable that they were totally laid aſide, till gunpowder and the modern ordnance ſuperſeded their uſe.

The firſt application of gunpowder to military affairs ſeems to have been ſoon after the year 1300, for which the propoſal of Friar Bacon, about the year 1280, for applying its enormous exploſion to the deſtruction of armies, might give the firſt hint; and Schwartz, to whom the invention of gunpowder has been erroneouſly aſcribed, might have been the firſt who actually applied it in this way; for, it is ſaid, that having pounded the materials of this mixture in a mortar, which he afterwards covered with a ſtone, a ſpark of fire accidentally flew into the mortar, and the exploſion blowed the ſtone to a conſiderable diſtance.

We ſhall here only mention the prohibition of fire-arms in the code of Gentoo laws, printed by the Eaſt India company in 1776, which ſeems to confirm the ſuſpicion ſuggeſted by a paſſage in Quintus Curtius, that Alexander the Great found ſome weapons of that kind in India. Cannon, in the Shanſcrit idiom, is called ſhet-aghnee, or the weapon that kills a hundred men at once. See CANNON.

However, the firſt pieces of artillery, charged with gunpowder and ſtone bullets of a prodigious weight, were of very clumſy and inconvenient ſize and ſtructure. (See CANNON.) Thus, when Mahomet the Second beſieged Conſtantinople in 1453, he battered the walls with ſtones of this kind, and with pieces, ſome of which were of the calibre of 1200 pounds, and which could not be fired more than four times a day. The matter and fabric of theſe unwieldy pieces were changed for others that were lighter and more manageable, and particularly for braſs cannon, about the cloſe of the fourteenth century. The formation of artillery, if we except the ingenious method of boring cannon, not long ſince invented, hath been little improved within the laſt two hundred years; the proportions of the beſt pieces being now much the ſame with thoſe that were made in the time of the emperor Charles V. but their uſe and application have undergone conſiderable changes, the ſame ends being now generally purſued by ſmaller pieces than thoſe which were formerly thought neceſſary; the manner of forming a breach, by firſt cutting off the whole wall as low as poſſible, before its upper part is attempted to be beat down, ſeems alſo to be a conſiderable improvement in the practical part of artillery; as is alſo that diſpoſition of artillery called the *battery à ricochet*, firſt uſed in 1692. But the theory of gunnery has made ſlower advances than the mechanical part. The firſt people who directed their attention to this ſubject were the Italians, about the beginning of the ſixteenth century. N. Tartagalia, the famous mathematician of Breſcia, who invented the method of ſolving cubic equations, generally aſcribed to Cardan, profeſſedly diſcuſſed the theory of projectiles, in his Nova Scientia, printed at Venice in 1537; and in his Quæſiti & Inventioni diverſi, in 1546; and in another work, tranſlated into Engliſh, under the title of Colloquies, concerning the art of ſhooting in great and ſmall pieces of artillery, and publiſhed at London in 1588; he is ſuppoſed to be the firſt who aſſerted, that the greateſt range of projectiles was at an elevation of 45°; and he alſo determined, contrary to the opinion of his contemporaries, that no part of the track deſcribed by a cannon-ball is a right line, though the curvature is in ſome caſes ſo ſmall as not to need attention. To him is likewiſe aſcribed the invention of the gunner's quadrant.

However, nothing deciſive was delivered as to the nature of the curve deſcribed by ſuch bodies till the time of Galileo, who diſcovered the law of acceleration in falling bodies, and publiſhed his celebrated Dialogues on Motion, in 1638. He deſcribed the action and effects of gravity on falling bodies, and on theſe principles determined, that the flight of any projectile would be in the curve of a parabola, unleſs ſo far as it were diverted from that track by the reſiſtance of the air; accordingly he has ſhewn, that a body, ſhot horizontally, would, in its flight, deſcribe half a parabola, and when the piece had an elevation above the horizon, a whole parabola, provided that it fell on the plane of the battery; he alſo proved, that, whatever the ranges of the projected body or the elevations of the piece were, the ball would ſtill trace that curve line, of a greater or leſs amplitude, by the time it deſcended to the level of the place from which it was projected. His diſciple, Torricelli, extended this theory, by ſhewing that, whether the ball fell above or below the plane of its projection, it deſcribed a parabola of a larger or a ſmaller amplitude, according to the angle of elevation of the piece and the ſtrength of the powder. Galileo was not unapprized of the effects of the air's reſiſtance, and he has propoſed the means of examining the inequalities which they would occaſion

ſion in the motion of a ball at ſome given diſtance from the piece; yet he expreſsly ſays, that "among theſe projectiles which we make uſe of, if they are of a heavy matter and round form, nay, if they are of a lighter matter, and have a cylindrical form, ſuch as arrows ſhot from bows, their track or path will not ſenſibly decline from the curve of a parabola." (See his fourth Dialogue on Motion.) In this theory his ſucceſſors for a conſiderable time acquieſced, without trying how far the real motions of projectiles deviated from a parabolic track, or deciding, whether the reſiſtance of the air was, or was not, neceſſary to be attended to in the determinations of gunnery. Admitting that no great variation could ariſe from the reſiſtance of the air, in the flight of balls, chiefly on account of the extreme rarity of the air compared with the denſe and ponderous compoſition of thoſe projected bodies, they eſtabliſhed it as a kind of general axiom, that the flight of theſe bodies is nearly in the curve of a parabola. Accordingly, in 1674, our countryman, Mr. Anderſon, publiſhed his treatiſe of the "Genuine Uſe and Effects of the Gun," in which he maintains the Galilean theory, and profeſſes to anſwer all objections that could be urged againſt it; and though he was obliged to infer from ſubſequent experiments, that the whole track of projected bodies was not parabolic, as appears by his treatiſe, entitled "To hit a Mark," publiſhed in 1690, yet, inſtead of aſcribing the deviation of their flight from the parabolic curve to the reſiſtance of the air, he framed an hypotheſis for reconciling his experiments with his doctrine; he ſuppoſed, that the bullet, at its firſt diſcharge, flew for a certain diſtance in a right line, from the end of which line it began to bend into a parabola; this right line, which he calls the *line of the impulſe of fire*, he ſuppoſes to be the ſame in all elevations; and, by aſſigning a proper magnitude to this line of impulſe, he was able to reconcile any two ſhot made at different angles, however oppoſite they might prove to the common principles. But this new modelled theory was not confirmed by his following experiments.

In the year 1683, Monſ. Blondel publiſhed, at Paris, a treatiſe, entitled "L'Art de jetter des Bombes," in which he labours to ſhew, that the retardation ariſing from the reſiſtance of the air is ſo very inconſiderable, as to be of no account in practice. This opinion was ſo generally received both in France and England, that there ſeem to have been none who ſuſpected its fallacy.

Dr. Halley, in a paper communicated to the Royal Society in 1686, expreſsly aſſerts, that in "large ſhot of metal, whoſe weight many times ſurpaſſes that of the air, and whoſe force is very great in proportion to the ſurface wherewith they preſs thereon, this oppoſition (occaſioned by the reſiſtance of the air to the motion of cannon-balls) is ſcarce diſcernible:" and from actual experiments he infers, that "although in ſmall and light ſhot the oppoſition of the air ought and muſt be accounted for, yet in ſhooting of great and weighty bombs, there need be very little or no allowance made." Phil. Tranſ. N° 179. p. 19. or Abr. vol i. p. 484. The practitioners in gunnery, though an erroneous theory had obtained the ſanction of ſo great a name as that of Dr. Halley, might have been led to ſuſpect its truth by the authority of a ſtill greater name, *viz.* that of ſir Iſaac Newton, who, in 1687, publiſhed his "Principia Mathematica Phil. Nat." in which he has demonſtrated, (ſee lib ii. § 7.) that the curve deſcribed by a projectile, in a ſtrongly reſiſting medium, differed much from a parabola, and that the reſiſtance of the air was great enough to make the difference between the curve of projection of heavy bodies and a parabola far from being inſenſible, and, therefore, too conſiderable to be neglected. The truth of theſe concluſions was farther eſtabliſhed by M. Huygens, in his "Diſcours de la Cauſe de la Peſanteur," Leide, 1690, in which he affirms, from experiments and mathematical inveſtigation, that the track of all projectiles was very different from the line of a parabola. However, the teſtimony of theſe writers produced little change in the general opinion; indeed M. Reſſons, a French officer of artillery, in a memoir preſented to the Royal Academy, in 1716, declares that theory was of very little ſervice in the uſe of mortars; that practice had convinced him there was no theory in the effects of gunpowder; for, having endeavoured, with the greateſt preciſion, to point a mortar agreeably to the calculations of M. Blondel, he had never been able to eſtabliſh any ſolid foundation upon them. One other inſtance occurs in which D. Bernouilli applies the doctrine of ſir Iſaac Newton to the motions of projectiles. Com. Acad. Petrop. tom. ii. p. 338, &c.

In this ſtate of error and unaccountable contradiction between theory and practice did the ſcience of gunnery remain, till the ingenious Mr. Robins, in the year 1742, publiſhed a ſmall treatiſe, entitled "New Principles of Gunnery," containing many curious diſcoveries relating to the force of gunpowder, the velocity of bullets impelled by its exploſion, the difference of the reſiſting power of the air to ſwift and ſlow motions, the deviation of the flight of projected bodies from the parabolic curve in a degree never diſcovered or ſuſpected by any, and the deflection of bullets and other projectiles from the vertical plane in which the ſhot is made, reſulting from a rotatory motion which they accidentally acquire about an axis. Theſe diſcoveries have been confirmed and improved by himſelf in ſubſequent publications, and by others, particularly M. Euler, of Berlin, who publiſhed it with a large commentary, in 1745; and by M. Le Roy of Paris, in the Mem. Acad. Sc. for 1751; and by Dr. Hutton of the Military Academy at Woolwich. The reader will find a more particular account of theſe diſcoveries in the ſequel of this article, and under the articles, CANNON, GUN, GUNPOWDER, PROJECTILE, RANGE, RESISTANCE, and RIFLE-*gun*.

Mr. Robins, from the experiments related in his "New Principles of Gunnery," having concluded, that the force of fired gunpowder, at the inſtant of its exploſion, is the ſame as that of an elaſtic fluid of a thouſand times the denſity of the common air, and that the elaſticity of this fluid, like that of the air, is proportionable to its denſity, inferred, that this elaſtic fluid, exiſting in the powder in an extremely condenſed ſtate, and being ſuddenly extricated from the powder by the combuſtion, expanded with an aſtoniſhing force, and violently impelled the bullet or whatever elſe oppoſed its expanſion. The intenſity of this force was aſcertained by Mr. Robins in different ways, after the example of Mr. Hawkſbee, for which ſee Phil. Tranſ. N° 295 and his "Phyſico-Mechanical Experiments," p. 31. See GUNPOWDER.

Mr. Robins, having thus determined the force of the gunpowder, as the intenſity of the agent by which the projectile is to be urged, proceeds to determine the effects it will produce, or the velocity with which it will impel a ſhot of a given weight from a piece of ordnance of given dimenſions. Accordingly he propoſed for ſolution the following problem: The dimenſions of any piece of artillery, the denſity of its ball, and the quantity of its charge being given, to determine the velocity which the ball will acquire from the exploſion, ſuppoſing the elaſticity or force of the powder at the firſt inſtant of its firing to be given.

In the ſolution of this problem he aſſumes the two following principles: 1. That the action of the powder on the bullet ceaſes as ſoon as the bullet is got out of the piece. 2. That all the powder of the charge is fired, and converted into an elaſtic fluid, before the bullet is ſenſibly moved from its place.

Theſe aſſumptions, and the concluſions before mentioned, make the action of fired gunpowder to be entirely ſimilar to that of air condenſed a thouſand times; and from thence it will not be difficult to determine the velocity of the ball ariſing from the exploſion: for the force of the fired powder diminiſhing in proportion to its expanſion, and ceaſing when the ball is out of the piece, the total action of the powder may be repreſented by the area of the curve, the baſe of which repreſents the ſpace through which the ball is accelerated; and the ordinates to which, repreſent the force of the powder at every point of that ſpace: and theſe ordinates being in reciprocal proportion to their diſtance from the breech of the gun, becauſe when the ſpaces occupied by the fired powder are as 1, 2, 3, 4, &c. the force of the powder, or the ordinates repreſenting it, will be as 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. it appears that the curve will be a common hyperbola, and that the area intercepted between it, its aſymptote, and the two ordinates repreſenting the force of the powder at the firſt exploſion and at the muzzle of the piece, will repreſent the total action of the powder on the ball; but if the ball were urged through the ſame ſpace, by an uniform force equal to its gravity, the total action of this force would be repreſented by a rectangle, the baſe of which would be the baſe of the curve or intercepted portion of the aſymptote before mentioned, and the height of which would repreſent the uniform force of gravity. Hence the ſquare of the velocity of the ball, reſulting from the action of the gunpowder, will be to the ſquare of the velocity, reſulting from the action of gravity, as the area of the hyperbolic ſpace is to the area of the rectangle: but the velocity of the ball reſulting from gravity is given, being the velocity it would acquire from a height equal to the ſpace through which the powder accelerates it; and the proportion between the hyperbolic ſpace and the rectangle is alſo given, from the analogy of hyperbolic ſpaces and logarithms; therefore the velocity of the ball ariſing from the action of the fired gunpowder will be given. This reaſoning may be illuſtrated by a view of *fig.* 3. *Plate* I. *Gunnery*, in which let A B repreſent the axis of any piece of artillery, A the breech, and B the muzzle; D C the diameter of its bore, and D E G C a part of its cavity filled with powder. Suppoſe the ball, that is to be impelled, to lie with its hinder ſurface at the line G E, then the preſſure exerted at the exploſion, on the circle of which G E is the diameter, or, which is the ſame thing, the preſſure exerted in the direction F B, on the ſurface of the ball, is eaſily known from the known dimenſions of that circle; draw any line F H perpendicular to F B, and A I parallel to F H, and through the point H, to the aſymptotes I A and A B, deſcribe the hyperbola K H N Q; then if F H repreſents the force impelling the ball at the point F, the force impelling the ball in any other place, as M, will be repreſented by the line M N, the ordinate to the hyperbola at that point; for when the fluid impelling the body along has dilated itſelf to M, its denſity will be then to its original denſity in the ſpace D E G C reciprocally as the ſpaces through which it is reſpectively extended; that is, as F A to M A, or as M N to F H; but it appears, that the elaſticity or impelling force of this fluid is directly as its denſity; therefore, if F H repreſents that force at the point F, M N will repreſent the like force at the point M.

Since the abſolute quantity of the force impelling the ball at the point F is known, and the weight of the ball is likewiſe known; the proportion between the force the ball is impelled with, and its own gravity, is known. In this proportion take F H to F L, and draw L P parallel to F B; then M N, the ordinate to the hyperbola in any point, will be to its part M R, cut off by the line L P, as the impelling force of the powder, in that point M, to the gravity of the ball; and conſequently, the line L P will determine a line proportional to the uniform force of gravity in every point; whilſt the hyperbola H N Q determines in like manner ſuch ordinates as are proportional to the impelling force of the powder in every point; whence, by the 39th propoſition of lib. i. of ſir Iſaac Newton's Phil. Nat. Prin. Math. the areas F L P B and F H Q B are in the duplicate proportion of the velocities which the ball would acquire, when acted on by its own gravity through the ſpace F B, and when impelled through the ſame ſpace by the force of the powder. But ſince the ratio of A F to A B, and the ratio of F H to F L are known, the ratio of the area F L P B to the area F H Q B is known; and thence its ſubduplicate. And ſince the line F B is given in magnitude, the velocity which a heavy body would acquire when impelled through this line by its own gravity, is known, being no other than the velocity it would acquire by falling through a ſpace equal to that line; find then another velocity, to which this laſt mentioned velocity bears the given ratio of the ſubduplicate of the area F L P B to the area F H Q B, and this velocity, thus found, is the velocity the ball will acquire when impelled through the ſpace F B by the action of the inflamed powder.

To give an example of this, let us ſuppoſe the length of a barrel of a gun, or A B, to be 45 inches, its diameter D C, or rather the diameter of the ball to be $\frac{3}{4}$ of an inch, and the ſpace occupied by the powder, A F, to be $2\frac{5}{8}$ inches; to determine the velocity which will be communicated to a leaden bullet by the exploſion, ſuppoſing the bullet laid at firſt with its ſurface contiguous to the powder.

By the theory here laid down it appears, that at the firſt inſtant of the exploſion the flame will exert, on the ball lying cloſe to it, a force one thouſand times greater than the preſſure of the atmoſphere. But the mean preſſure of the atmoſphere is eſteemed equal to that of a column of water 33 feet high; whence, lead being to water as 11.345 to one, this preſſure will be equal to that of a column of lead 34.9 inches in height; whence, multiplying this by 1000, a column of lead 34900 inches high would produce a preſſure equal to what is exerted on the ball by the powder in the firſt inſtant of the exploſion; and the leaden ball being $\frac{3}{4}$ of an inch in diameter, and conſequently, equal to a cylinder of lead on the ſame baſe $\frac{1}{2}$ an inch in height, the preſſure at firſt acting on it will be equal to 34900 × 2, or 69800 times its weight; whence the force of gravity, F L, is to that of the powder at its firſt exploſion, F H, as 1 to 69800: and F B to F A is as 45 — $2\frac{5}{8}$ (or $42\frac{3}{8}$) to $2\frac{5}{8}$; that is, as 339 to 21: whence the rectangle F L P B, is to the rectangle A F H S, as 339 to 21 × 69800; that is, as 1 to 4324—. And from the known application of the logarithms to the menſuration of the hyperbolic ſpaces, it follows, that the rectangle A F H S, is to the area F H Q B as .43429, &c. is to the tabular logarithm of $\frac{A B}{A F}$; that is, of $\frac{45}{2\frac{5}{8}}$, which is 1.2340579; whence the ratio of the rectangle F L P B to the hyperbolic area F H Q B is compounded of the ratios of 1 to 4324—, and of .43429, &c. to 1.2340579; which

which together make up the ratio of 1 to 12263, the ſubduplicate of which is the ratio of 1 to 110.7; and in this ratio is the velocity, which the bullet would acquire by gravity, in falling through a ſpace equal to F B, to the velocity the bullet will acquire from the action of the powder, impelling it through F B; but the ſpace F B being $42\frac{1}{4}$ inches, the velocity a heavy body will acquire in falling through ſuch a ſpace is known to be, what would carry it nearly at the rate of 15.07 feet in 1″ of time; whence the velocity, to which this has the ratio of 1 to 110.7 is a velocity, which would carry the ball at the rate of 15.07 × 110.7 feet in 1″ of time; that is, at the rate of 1668 feet in 1″ of time. And this is the velocity, which, according to the theory, the bullet in the preſent circumſtances would acquire from the action of the powder, during the time of its dilatation. And this being once computed for one caſe, is eaſily applied to any other; for if the cavity D E G C left behind the bullet be only in part filled with powder, then the line H F, and conſequently the area F H Q B will be diminiſhed in the proportion of the whole cavity to the part filled; if the diameter of the bore be varied, the lengths A B and A F remaining the ſame, then the quantity of powder and the ſurface of the bullet, which it acts on, will be varied in the duplicate proportion of the diameter; but the weight of the bullet will vary in the triplicate proportion of the diameter; wherefore the line F H, which is directly as the abſolute impelling force of the powder, and reciprocally as the gravity of the bullet, will change in the reciprocal proportion of the diameter of the bullet. If A F, the height of the cavity left behind the bullet, be increaſed or diminiſhed, the rectangle of the hyperbola, and conſequently the area correſponding to ordinates in any given ratio, will be increaſed or diminiſhed in the ſame proportion. From all which it follows, that the area F H Q B, which is in the duplicate proportion of the velocity of the impelled body, will be directly as the logarithm $\frac{A B}{A F}$, (where A B repreſents the length of the barrel, and A F the length of the cavity left behind the bullet,) alſo directly as the part of that cavity filled with powder, and inverſely as the diameter of the bore, or rather of the bullet, likewiſe directly as A F the height of the cavity left behind the bullet. Conſequently the velocity being computed above, for a bullet of a determined diameter, placed in a piece of a given length, and impelled by a given quantity of powder, occupying a given cavity behind that bullet; it follows, that by means of theſe ratios the velocity of any other bullet may be thence deduced, the neceſſary circumſtances of its poſition, quantity of powder, &c. being given. Where note, that in the inſtance of this propoſition we have ſuppoſed the diameter of the ball to be $\frac{3}{4}$ of an inch: whence the diameter of the bore will be ſomething more, and the quantity of powder contained in the ſpace D E G C will amount to exactly 12dwt. a ſmall wad of tow included. If the ſeveral quantities above ſpecified are expreſſed by algebraic ſymbols, we ſhall have the following ſtatement and general reſult: let v be the velocity of the ball, a the length of the charge of powder, b the whole length of the bore, c the ſpecific gravity of the ball, or weight of a cubic foot of the ſame matter in ounces, d the diameter of the bore, and w the weight of the ball in ounces. Then $v = 27130 \sqrt{\frac{10a}{cd}} \times \log. \frac{b}{a}$ or $= 100 \sqrt{\frac{223 a d^2}{w}} \times \log. \frac{b}{a}$.

E. G. Suppoſe $a = 2\frac{5}{8}$ inches, $b = 45$ inches, $c = 11345$ oz. for a ball of lead, and $d = \frac{3}{4}$ inch: then $v = 27130 \sqrt{\frac{7}{2269}} \times \log. \frac{120}{7} = 1674$ feet, the velocity of the ball, *per* ſecond. Or, if the weight of the bullet be $w = 1\frac{9}{20}$ oz. $= \frac{29}{20}$ oz. Then $v = 100 \sqrt{\frac{1115 \times 189}{29 \times 52}} \times \log. \frac{120}{7} = 1674$ feet, as before.

As to the firſt of the principles here aſſumed, the author has obſerved, (ſee alſo his Mathematical Tracts, vol. i. p. 164, &c.) that it would be found erroneous, if examined with a geometrical rigour; ſince it cannot be queſtioned but the flame acts in ſome degree on the bullet after it is out of the piece: but, in experiments, no ſuch accuracy is attainable; minute irregularities are the neceſſary concomitants of all complicated experiments: in the colliſion of bodies, in the running or ſpouting of water, even in ſmall velocities, irregularities happen not reconcileable to theory or to each other; what may not then be ſuppoſed to happen from the action of ſo furious a power as gunpowder? From experiments it appears, that the velocities of bullets fired from the ſame piece, charged with the ſame powder, and all other circumſtances as nearly as poſſible the ſame, do yet differ from each other by ſometimes more than $\frac{1}{30}$th part of the whole; but this is a ſmall degree of inaccuracy in a caſe of this nature, and if the action of the flame on the bullet, after it is out of the piece, is ſo ſmall as to produce no greater effect than what may be deſtroyed by the inevitable variations of the experiments, the neglecting it entirely is both convenient and a reaſonable procedure. Now, what gives ground to think that this poſtulatum, though not rigorouſly true, may be ſafely aſſumed, is the conſideration of the ſpreading of the flame by its own elaſticity, as ſoon as it eſcapes from the mouth of the piece; for by this it may be conceived that the part of it which impinges on the bullet may be neglected, although the impulſe of the flame be a very remarkable force.

With regard to the ſecond aſſumed principle, that all the powder is fired before the bullet is ſenſibly moved from its place, it is to be obſerved, that this very poſition, having been examined by a committee of the Royal Society, was, after ſeveral experiments, determined in the negative, from whence many may be ready to conclude, that the whole theory muſt be overturned. But this requires a farther diſcuſſion; and it will appear, that though this principle be not rigorouſly true, no more than the former, yet it ſeems alſo that it may be ſafely admitted in inveſtigating the effects of powder, ſince, even in ſhort barrels, where the ſpace the bullet was impelled through was not five inches, and where of courſe the deficiency of velocity was greateſt, it cannot amount to one thirtieth of the whole. This will appear from the experiments made by the committee; for when the barrel was ſo ſhortened, that the bullet, being placed cloſe to the wad, lay with its outer ſurface nearly level with the mouth of the piece, yet, even in this ſhort tranſit of the bullet, but $\frac{1}{6}$ of the whole charge, at a medium, was collected unfired, which $\frac{1}{6}$, properly reduced, amounts to but $\frac{1}{30}$ of the charge. This reduction is founded on theſe conſiderations, that the powder uſed by the committee being unequally grained, when the ſmaller grains, collected by ſifting, were uſed, the quantity remaining unfired was leſs at the medium in the ratio of 5 to 3, than when it was uſed without ſifting. Alſo, by extracting the ſalt-petre from the powder collected unfired, there

was leſs ſalt-petre contained in it than in real powder, nearly in the ratio of 9 to 7. Now theſe two proportions compounded, make the proportion of 15 to 7, in which proportion muſt the quantities of powder unfired be reduced, in order to determine the quantity of fine good powder that might be ſuppoſed to remain unfired in the experiments brought to confirm the aforeſaid theory.

Now, it appears, by experiments, that the velocities of bullets placed in the ſame ſituation, are in the ſub-duplicate proportion of the charges; conſequently the deficiency of the velocity ariſing from the loſs of $\frac{1}{12}$ of the charge will be about $\frac{1}{24}$ of the velocity only. And in the experiments made with a barrel 5½ inches in length, where the ball had not three inches to move, the quantity of real powder collected unfired from a charge of 12dwt, would have been no more than 16 grains, at a medium, or $\frac{1}{15}$ of the whole charge, which would produce a deficiency of $\frac{1}{30}$ of the velocity only: a difference leſs than what frequently occurs in the exacteſt repetition of the ſame experiments.

This, it is thought, is fully ſufficient to juſtify the principle in queſtion; eſpecially, as in all caſes of real uſe, the length of the barrel, in proportion to the quantity of the charge, will be much greater than in the inſtances here mentioned. See Phil. Tranſ. N° 469, p. 450, 452, &c. or Martyn's Abr. vol. viii. p. 260. or Robins's Math. Tracts, vol. i. p. 164, &c. and ſee the experiments of the committee in the Tranſactions, N° 465. p. 172, 173, &c. or Martyn's Abr. vol. viii. p. 253, &c.

The greateſt number of thoſe who have written on the manner in which powder takes fire, have ſuppoſed it to be done by regular degrees; the firſt grains firing thoſe contiguous, and they the next ſucceſſively; and it has been generally thought that a conſiderable time was employed in theſe various communications: for Mr. Daniel Bernouilli, in his Hydrodynamica, has concluded, from ſome experiments made at Peterſburgh, that the greateſt part of the charge eſcapes out of the piece unfired, and that the ſmall part which is fired does not take fire till it is near the mouth. Many theories too have been compoſed on the time of the progreſs of the fire amongſt the grains, and the different modifications which the force of powder did thence receive; and it has been generally conceived, that the proper lengths of pieces were determinable from this principle; ſo that they ſhould be long enough to give time for all the powder to fire.

But no ſuch regular and progreſſive ſteps ſeem obſervable in the exploſion, for conſidering that by loading with a greater weight of bullet, and hereby almoſt doubling the time of the continuance of the powder in the barrel, its force receives but an inconſiderable augmentation; and that doubling and trebling the uſual charge, the powder thus added always produces a correſpondent effect in the velocity of the bullet; likewiſe, that in a piece near four feet in length, charged with an uſual charge of powder, the velocity communicated to the bullet, during the firſt three inches of its motion, is full half the velocity acquired in its whole paſſage through the barrel; and conſidering alſo that the elaſticity or force of the powder, in the three firſt inches of its expanſion, is at a medium near eight times greater than in the two laſt feet of the barrel; it may be concluded from all theſe circumſtances, that the time employed by the powder in taking fire was not neceſſary to be attended to in theſe computations; but that the whole maſs might be ſuppoſed to be kindled, before the bullet was ſenſibly moved from its place.

And the experiments reported by the committee of the Royal Society, before-mentioned, are ſtrong proofs that the powder is not fired in the progreſſive manner uſually ſuppoſed; for when the ſhort barrel was charged with twelve penny-weight and ſix penny-weight reſpectively, the quantity of powder which was collected unfired from twelve penny-weight, did not exceed by three grains, at a medium, what was collected from ſix penny-weight, although the bullet was a leſs time in paſſing through the barrel with twelve penny-weight than with ſix, it having a leſs way to move; conſequently the quantity remaining unfired of the ſix penny-weight, did not continue unfired for want of time; ſince when the piece was charged with twelve penny-weight, the additional ſix penny-weight was conſumed in a ſhorter time. See Phil. Tranſ. N° 469. p. 450. or Robins, &c. ubi ſupra.

Mr. Robins has alſo given us an ingenious way of determining, by experiments, the velocity which any ball moves with, at any diſtance from the piece it is diſcharged from.

This may be effected by means of a pendulum made of iron, having a broad part at bottom, covered with a thick piece of wood which is faſtened to the iron by ſcrews. Then having three poles joined together by their tops, and ſpreading at bottom, ſuch as are vulgarly uſed in weighing and lifting heavy bodies, and called by workmen triangles; on two of theſe poles, towards their tops, are ſcrewed ſockets, on which the pendulum is hung by means of a croſs-piece, which becomes its axis of ſuſpenſion, and on which it ought to vibrate with great freedom. Something lower than the bottom of the pendulum there ſhould be a brace, joining the two poles to which the pendulum is ſuſpended; and to this brace there is faſtened a contrivance made with two edges of ſteel, ſomething in the manner of a drawing pen; the ſtrength with which theſe edges preſs on each other being diminiſhed or increaſed at pleaſure, by means of a ſcrew. To the bottom of the pendulum ſhould be faſtened a narrow ribbon, which paſſing between the ſteel edges, may hang looſely down by means of an opening cut in the lower piece of ſteel.

The inſtrument being thus fitted, if the weight of the pendulum, the reſpective diſtances of its centre of gravity, and of its centre of oſcillation from its axis of ſuſpenſion be known, it may from thence be found what motion will be communicated to this pendulum by the percuſſion of a body of a known weight moving with a known degree of velocity, and ſtriking it in a given point; that is, if the pendulum be ſuppoſed at reſt before the percuſſion, it will be known what vibration it ought to make in conſequence of ſuch a blow; and if the pendulum, being at reſt, is ſtruck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the ſtriking body may from thence be determined.

Now the extent of the vibration, made by the pendulum, may be meaſured by the ribbon. For if the preſſure of the ſteel edges on the ribbon be regulated by the ſcrew, ſo as to be free and eaſy, though with ſome minute reſiſtance to hinder its ſlipping of itſelf, then ſetting the pendulum at reſt, let the part of the ribbon between the pendulum and ſteel edges be drawn ſtraight, but not ſtrained; and fixing a pin in the part of the ribbon contiguous to the edges, the pendulum ſwinging back by the impulſe of the ball, will draw out the ribbon to the juſt extent of its vibration, which will be determined by the interval on the ribbon between the edges and the place of the pin.

The computation by which the velocity of the ball is de-

termined, from the vibration of the pendulum after the ſtroke, is founded on this principle of mechanics: that if a body in motion ſtrikes on another at reſt, and they are not ſeparated after the ſtroke, but move on with one common motion, then that common motion is equal to the motion with which the firſt body moved before the ſtroke; whence, if that common motion and the maſſes of the two bodies are known, the motion of the firſt body before the ſtroke is thence determined. On this principle it follows, that the velocity of a bullet may be diminiſhed in any given ratio, by its being made to impinge on a body of a weight properly proportioned to it; and hereby the moſt violent motions, which would otherwiſe eſcape our examination, are eaſily determined by the retarded motions which have a given relation to them. See New Princip. of Gunnery, p. 28, 29, &c. See alſo the Phil. Tranſ. N° 469. p. 444. where a ſmall correction, relating to a number in Mr. Robins's 8th propoſition is mentioned; or Math. Tracts, vol. i. p. 83, &c. and p. 163, &c.

It is to be obſerved, that the length to which the ribbon is drawn, is always nearly the chord of the arch deſcribed by the aſcent; it being ſo placed, as to differ inſenſibly from thoſe chords which moſt frequently occur; and theſe chords are known to be in the proportion of the velocities of the pendulum acquired from the ſtroke. Hence it follows, that the proportion between the lengths of ribbon drawn out at different times, will be the ſame with that of the velocities of the impinging bullets.

Now from the computations delivered by Mr. Robins, it appears, that the velocity of a bullet, whoſe weight was $\frac{1}{77}$ of a pound, was 1641 feet in one ſecond of time, when the chord of the arch deſcribed by the aſcent of the pendulum, in conſequence of the blow, was $17\frac{1}{4}$ inches. Therefore, by the proportion of any other lengths of ribbon drawn out, by any percuſſion, to $17\frac{1}{4}$, the proportion of the velocity with which the bullets impinge, to the known velocity of 1641 feet in 1″, will be determined.

As experiments of this kind are often attended with danger and difficulty, thoſe who may be diſpoſed to make any, will find ſeveral uſeful practical cautions, in p. 31, 32, and 33, of the ſaid treatiſe.

Mr. Thompſon (count Rumford) has made many experiments for determining the velocities of bullets by means of a pendulum, according to the method of Mr. Robins; for an account of which ſee Phil. Tranſ. for 1781, vol. lxxi. Dr. Hutton, in his "Tracts," (vol. i. p. 119,) has given a ſimpler rule than that of Mr. Robins, or of M. Euler and Antoni, who followed him in this buſineſs, for computing velocities from experiments with the machine above deſcribed; and the rule is expreſſed by either of the two following formulas: *viz.* $v = 5.6727\, c\, g \times \frac{p+b}{bir}\sqrt{o} = 614.58\, c\, g \times \frac{p+b}{birn}$, the velocity, where v denotes the velocity of the ball when it ſtrikes the pendulum, p the weight of the pendulum, b the weight of the ball, c the chord of the arc deſcribed by the vibration to the radius r, g the diſtance below the axis of motion to the centre of gravity, o the diſtance to the centre of oſcillation, i the diſtance to the point of impact, and n the number of oſcillations performed by the pendulum in one minute, when made to oſcillate in ſmall arcs. The latter of theſe two theorems is much the moſt eaſy, both becauſe it is free from radicals, and becauſe the value of the radical $\sqrt{o}$ in the former, is to be firſt computed from the number n, the number of oſcillations which the pendulum is obſerved to make.

By the experiments recited at large, in propoſition IX. of the ſame treatiſe, it appears, that the computations from Mr. Robins's theory, compared with thoſe experiments which were made with barrels of various lengths, from ſeven inches to forty-five, and with different quantities of powder, from ſix penny-weight to thirty-ſix, have a remarkable coincidence, and ſuch as occurs but in a few philoſophical ſubjects of ſo complicated a nature.

Suppoſing, for inſtance, the length of a barrel to be 45 inches, the quantity of powder 12 penny-weight, the cavity containing it $2\frac{5}{9}$ inches, and the ball $\frac{3}{4}$ inches diameter, weighing $1\frac{1}{3}$ ounce, or $\frac{1}{16}$ of a pound avoirdupoiſe, and the windage or exceſs of the diameter of the barrel above that of the bullet about $\frac{1}{50}$ of an inch; the velocity of the bullet will, by theory, be about 1670 feet in one ſecond, and this velocity is found in theſe experiments, to be the mean velocity which the ball really receives in thoſe circumſtances. Hence we may determine the velocities with which muſket and cannon-ſhot are diſcharged from their reſpective pieces, by their uſual allotment of powder.

For as a leaden ball of $\frac{3}{4}$ inch diameter, and weighing nearly $1\frac{1}{7}$ ounce avoirdupoiſe, being fired from a barrel of 45 inches in length, with half its weight of powder, will have a velocity at its iſſuing from the piece, which, if uniformly continued, would carry it near 1700 feet in 1″; ſo if inſtead of a leaden ball an iron one of the ſame diameter was placed in the ſame ſituation in the ſame piece, and was impelled by the ſame quantity of powder, the velocity of ſuch an iron bullet would be greater than that of the leaden one, in the ſubduplicate ratio of the ſpecific gravities of lead and iron; and ſuppoſing that ratio to be as 3 to 2, and computing on the foregoing principles, it will appear, that an iron bullet of 24*lb.* weight, ſhot from a piece of ten feet in length, with 16*lb.* of powder, will acquire from the exploſion a velocity, which, if uniformly continued, would carry it nearly 1650 feet in 1″. But if inſtead of this full charge, weighing two-thirds of the ball, we ſuppoſe the charge to be only half that weight, then its velocity would be no more than at the rate of 1490 feet in 1″; and the ſame would be the velocities of every leſſer bullet, fired with the ſame proportions of powder, if the lengths of all pieces were conſtantly in the ſame ratio with the diameters of their bore; and though this proportion does not always hold, yet the difference is not conſiderable enough to occaſion a very great variation from the velocities here aſſigned. But in theſe determinations, the windage is ſuppoſed to be no more than is juſt neceſſary for the eaſy putting down the bullet; whereas in real ſervice, either through negligence or unſkilfulneſs, it often happens, that the diameter of the bore ſo much exceeds the diameter of the bullet, that great part of the inflamed fluid eſcapes by its ſide; whence the velocity of the ſhot may, in this caſe, be conſiderably leſs than what is here aſſigned: however part of this may poſſibly be compenſated by the greater heat which in all probability attends the firing theſe large quantities of powder.

The theory here eſtabliſhed ſuppoſes what is ſaid under the head GUNPOWDER, that the powder when fired is equally hot with iron at the beginning of its white heat; but in very ſmall quantities of powder the heat is probably leſs, and conſequently the elaſticity leſs than what ariſes from this ſuppoſition. Now this decreaſe of elaſticity in ſmall quantities of powder has been found in many trials actually to take place. For inſtance, according to the theory before laid down, the velocity given the ball by the action of the powder, is in round numbers 1670 feet in 1″; and this, as has been ſaid, is confirmed by the experiments taken at a medium. If now the barrel and poſition of the ball

ball remaining the ſame, there be placed in the ſpace that contained twelve penny-weight of powder there mentioned, only one penny-weight; it follows, that if the elaſticity of the ſmaller charge be the ſame in proportion to its quantity with that of the larger, then the velocity of the bullet, when impelled by the exploſion of the ſmaller charge, will be to the velocity of a bullet impelled by a greater charge in the ſubduplicate ratio of the quantities of the reſpective charges, that is, in the ſubduplicate ratio of 1 to 12. Conſequently the velocity communicated by twelve penny-weight, being known to be that of 1670 feet in 1″, the velocity communicated by one penny-weight would be that of 482 feet in 1″ nearly; but by repeated trials, differing little from each other, it has been found, that the real velocity acquired by the ball in this caſe, from the exploſion of one penny-weight, was rather leſs than that of 400 feet in 1″. Whence it is evident, that the elaſticity of one penny-weight of powder, when fired, is leſs in proportion to its quantity than that of twelve penny-weight, as it ought to be by the theory.

So if three penny-weight of powder be placed in the ſame manner with the one penny-weight laſt-mentioned, the real velocity the ball will acquire from the exploſion will be from 740 to 720 feet in 1″. Whereas, ſuppoſing the elaſticity of three penny-weight, when fired, to be in ſimilar circumſtances the ſame with that of twelve penny-weight, the velocity acquired by the ball ſhould be 825 feet in 1″.

It is farther to be obſerved, that the theory eſtabliſhed under the head GUNPOWDER, ſuppoſes that in the firing of gunpowder about $\frac{1}{17}$ of its ſubſtance is converted by the ſudden inflammation into a permanent elaſtic fluid, the elaſticity of which in proportion to its heat and denſity, is the ſame with that of the common air in the like circumſtances: it farther ſuppoſes, that all the force exerted by gunpowder in its moſt violent operations, is no more than the action of the elaſticity of the fluid thus generated; and theſe principles enable us to determine the velocities of bullets impelled from fire-arms of all kinds.

From this theory appears the inconcluſiveneſs of what ſome authors have advanced relating to the advantages of particular forms for the chambers of mortars and cannon; for all their laboured ſpeculations on this head are evidently founded on very erroneous opinions about the actions of fired powder. Lib. cit. p. 99.

But it muſt not be diſſembled, that however probable this theory may be from the experiments and reaſons on which it is founded, there ſtill remains a difficulty which ſeems not yet fully accounted for. The doubt ariſes from ſome experiments made before a committee of the Royal Society, who hereupon gave it as their opinion, that the change of the form in the chamber will produce a change of the diſtance to which the bullet is thrown. The experiments upon which this opinion was founded, were as follow:

Three braſs chambers were made, whoſe depths were reſpectively three inches, 1½ inch and ¾ inch; ſo turned as to fit the chamber of a braſs mortar exactly; each of theſe chambers contained, when full, one ounce troy of powder. The ball was of braſs, weighing nearly 356 ounces troy: the ball touched the powder of the charge in all theſe experiments. With the firſt chamber of three inches deep, the elevation of the mortar being 45°, the range taken at a medium of three ſhot was 741 feet; and the mean diſtance to which the ball was thrown with the chamber of ¾ inch deep, was but 464 feet. As to the chamber of 1½ inch, it not fitting the chamber of the mortar exactly, the ranges were very irregular; but the leaſt range, though fired late in the damp of the evening, exceeded the fartheſt range of the ¾ inch chamber, and the fartheſt range extended to 686 feet; ſo that the committee ſeem well warranted in their opinion. The difficulty is to reconcile this with the foregoing theory. Its ingenious author has in general obſerved, in the account of his book given in the Phil. Tranſ. N° 469. p. 455. or Tracts, &c. vol. i. p. 173, that when the charge is much ſmaller than the uſual allotment of powder, there are ſome irregularities, as thoſe ariſing from the different heat of ſmall and large quantities of powder, to which head too perhaps muſt be referred the experiments made by the committee on the effect of different ſmall chambers; but in cuſtomary charges, the velocities of bullets reſulting from all the experiments hitherto made are really ſuch as the theory requires. And it appears, that theſe velocities are much greater than what they have been hitherto accounted; and there are reaſons from the theory to believe, that in cannon-ſhot the velocities may ſtill exceed the foregoing computation. See Phil. Tranſ. N° 465. or Martyn's Abr. vol. viii. p. 253, &c.

If a bullet be laid at a conſiderable diſtance from the charge, the principles before laid down cannot then be applied to determine the velocity of the ball; they being only applicable in caſes where the bullet is contiguous to the charge, or nearly ſo. For by what is ſhewn under the article GUNPOWDER, when the ſurface of fired powder is not confined by a heavy body, which it is obliged to impel before it, the flame dilates itſelf with a velocity, much beyond what it can at any time communicate to a bullet by its continued preſſure; becauſe the powder having acquired a conſiderable degree of velocity of expanſion, the firſt motion of the ball will not be produced by the continual preſſure of the powder, but by the percuſſion of the flame. From whence it follows, that the velocity of a bullet, laid at a conſiderable diſtance before the charge, ought to be greater than what would be communicated to it by the preſſure of the powder acting as before mentioned in this article. And this deduction from theory is confirmed from experience, by which it was found that a ball laid in a barrel, at the diſtance of 11¼ inches from the breech, and impelled by twelve penny-weight of powder, acquired in its diſcharge a velocity of about 1400 feet in 1″; whereas if it had been acted on by the preſſure of the flame only, it would not have acquired a velocity of 1200 feet in 1″. The ſame was found to hold true in all other great diſtances (and alſo in leſſer, though not in the ſame degree) and in all quantities of powder. And from hence ariſes a conſideration of conſequence in practice, which is, that no bullet ſhould at any time be placed at any conſiderable diſtance before the charge, unleſs the piece be extremely well fortified; for a moderate charge of powder, when it has expanded itſelf through the vacant ſpace, and reaches the ball, will, by the velocity each part has acquired, accumulate itſelf behind the ball, and be thereby prodigiouſly condenſed; whence if the barrel be not extraordinarily ſtrong, it muſt burſt. This is confirmed by the experience of an exceeding good Tower muſket of very tough iron, which being charged with twelve penny-weight of powder, and the ball being placed ſixteen inches from the breech, upon firing the piece, part of the barrel, juſt behind the bullet, was ſwelled out to double its diameter, and two large pieces burſt out of it. If the powder be not placed together at the breech, but ſcattered uniformly through the whole cavity left behind the bullet, the progreſſive motion of the flame may hence be ſuppoſed to be prevented by the expanſion of the neighbouring parts. And it was found that the ball, being laid as before, 11¼ inches from the breech, its velocity, in this caſe, inſtead of 1400 feet in 1″, was only 1100 feet. See New Principles of Gunnery, part i. prop. 12. or Tracts, &c. p. 113, &c.

It

It appears from experience, that bullets of the ſame diameter and denſity impinging on the ſame ſolid ſubſtance with different velocities, will penetrate that ſubſtance to different depths, which will be in the duplicate ratio of thoſe velocities nearly. Thus a leaden bullet of $\frac{3}{4}$ of an inch in diameter, being fired againſt a ſolid block of elm with different velocities, as of 1700 feet, 730, and 400 feet in 1″, the cavities were found to be as 55, 10, and 3, reſpectively; which are nearly in the duplicate proportion of thoſe velocities: perfect regularity in caſes of this nature cannot be expected, when the unequal texture of the ſame piece of wood, and the change of the form, and the bullet by the ſtroke, are conſidered.

From the penetration being in the duplicate proportion of the velocity of the impinging body, it follows, that the reſiſtance of the wood, like that of gravity, is uniform. See New Princip. of Gunnery, p. 94, 95. or Tracts, &c. p. 152. See Gun.

It appears from the account already given of Mr. Robins's admirable experiments, that the balls he made uſe of, in aſcertaining their initial velocity, were very ſmall, being only muſket balls of about one ounce in weight; but other occupations, and his immature death, prevented his proſecuting his experiments with others of a larger ſize. This defect is now, in a very conſiderable degree, ſupplied by the experiments of Dr. Charles Hutton, conducted in 1775 in conjunction with ſeveral able officers of the Royal Artillery, and other ingenious perſons; in which he has made uſe of ſmall cannon balls, from one pound to near three pounds weight, and formed a variety of concluſions, which may be applied to cannon-ſhot of the largeſt ſize. The machinery uſed by Dr. Hutton is much of the ſame kind with that of Mr. Robins; and the intention of his experiments is to diſcover the inicial velocity of military projectiles, or the velocity with which a ball iſſues from a piece.

The gun with which the experiments were made was of braſs; the diameter of the bore at the muzzle was 2.16 inches, and at the breech 2.08 inches; and the greateſt caſt iron ball, which it would admit, was $19\frac{1}{2}$ ounces avoirdupoiſe; but leaden balls weighing $1\frac{1}{4}$ pound, and long cylindrical ſhot weighing near three pounds, were ſometimes uſed; the length of the bore was 42.6 inches, ſo that it was nearly $20\frac{1}{2}$ calibres long. The powder was that commonly made for government, and the charge was 2, 4, or 8 ounces, put into a light flannel bag, and rammed without uſing any wad before it. The diſtance of the gun from the pendulum was 29 or 30 feet; and the depth of the penetration ſeemed to be near three inches in ſolid wood, when two ounces of powder were uſed. The firſt courſe of experiments was performed in May 1775, the day being clear and dry; and it appears from the reſult, that the mean velocity of five ſhot, with two ounces of powder, was 626 feet in 1″, and of two ſhot, with four ounces of powder, 915 feet in 1″, which velocities are in the ratio of 1 to 1.46. But the mean weight of the balls in the former caſe was $17\frac{1}{2}$ ounces, and in the latter $17\frac{1}{4}$ ounces, and the ratio of the quantities of powder was that of 1 to 2. In this inſtance it is evident, the velocities are very nearly as the ſquare roots of the quantities of powder directly, and the ſquare roots of the weights of the balls inverſely. The ſecond courſe of experiments was performed in June, in a clear and dry, but windy day. The mean velocity of the ſecond and third ſhot, in the experiments, was 973 feet in 1″, and of the fourth and fifth, 749 feet in 1″, which numbers are in the ratio of 1.3 to 1; the charges were two ounces, and the balls were $19\frac{1}{2}$ ounces and $46\frac{1}{2}$ ounces reſpectively. In this inſtance, the velocity of the heavier ſhot is a little leſs than what would ariſe from the inverſe ratio of the ſquare roots of the weight of the ſhot. Some of theſe experiments were rendered doubtful by the effect of the wind; but as the mean velocity is 973, and only 626 in the former courſe, with the ſame charge of powder, though the balls were heavier with the greater velocity, in the proportion of 19 to 17 nearly, Dr. Hutton aſcribes this remarkable difference chiefly to the windage in the firſt courſe, and takes occaſion from hence to recommend the uſe of balls approaching in proportion nearer to the diameter of the bore of the gun than what is preſcribed in the preſent eſtabliſhment. The next courſe of experiments was performed on a clear, dry, and calm day, in the ſame month. In ſix ſhot on this occaſion, the common mean weight of the ball was $18\frac{3}{4}$ ounces; the mean velocity with two ounces of powder was 738 feet in 1″, and that with four ounces 1043 feet in 1″; the ratio of which velocities is that of 1 to 1.414; or accurately the ratio of the ſquare roots of the quantities of powder. The fourth courſe was performed with another machine on a fine clear day in July. The machinery for this and the following courſe, ſays Dr. Hutton, was ſo perfect, and every circumſtance attending the experiments ſo carefully obſerved, that the concluſions reſulting from them may be relied on with great ſafety. Thoſe of the firſt day were made with leaden balls, and thoſe of the other with iron ones, which differed greatly in weight; and as every other circumſtance was the ſame, they afford very good means for diſcovering the law of the different weights of ſhot, while the variations in the powder from 2 to 4 and 8 ounces, furniſh us with the rule for the different quantities of it. The mean velocities with 2, 4, and 8 ounces of powder, were 613, 873, and 1162 feet in 1″, which are in the ratio of 1, 1.424 and 1.9; and theſe numbers are nearly in the ratio of the ſquare roots of the quantities of powder, *viz.* 1, 1.414 and 2. The mean weight of the balls uſed with 8 ounces of powder was $28\frac{1}{3}$ ounces; and that with the 2 and 4 ounces $28\frac{1}{3}$; the reciprocal ſubduplicate ratio of theſe is that of 1 to 1.006, in which proportion, increaſing 1.9, the number for the greater velocity, and it becomes 1.91, which falls ſhort of 2 by .09, or about the $\frac{1}{21}$d part too ſmall for the ſubduplicate ratio of the powder. This defect is aſcribed to three cauſes, *viz.* the leſs length of cylinder through which the ball was impelled: the greater quantity of elaſtic fluid which eſcaped in this caſe than in the others by the windage, on account of the greater velocity; and the greater quantity of powder blown out unfired in this caſe than in that of the leſs velocities. Hence we may infer, how ſmall the quantity of powder which is blown out unfired in any of theſe caſes, and the amazing quickneſs with which it fires in all caſes; for although the time in which the ball paſſed through the barrel, when impelled by the eight ounces of powder, was not much different from the half only of the time in which it was impelled by the two ounces, it is evident that in half the time there was nearly four times the quantity of powder fired. In the laſt courſe of experiments, conſiſting of fifteen ſhot, the mean velocities with 2, 4, and 8 ounces of powder, were 701, 993, and 1397 feet in 1″, which are as the numbers 1, 1.416 and 1.993, or nearly in the ſubduplicate ratio of the weights of powder, *viz.* 1, 1.414 and 2. The mean weight of the balls, which were iron, with the 2 and 4 ounces of powder, was $18\frac{3}{4}$ ounces, and with the 8 ounces of powder $18\frac{1}{3}$ ounces; and, therefore, if the number 1.993 be diminiſhed in the reciprocal ſubduplicate ratio of $18\frac{1}{3}$ to $18\frac{3}{4}$, it will become 1.985, which falls ſhort of the number 2 by .015, or the 133d part of itſelf; and this defect is to be aſcribed to the cauſes mentioned in the recital of the former courſe.

By comparing the correſponding velocities in theſe two laſt courſes, *viz.* 613 and 701, &c. it will be found that the ratio of the firſt, or of the velocities with two ounces of powder, is that of 1 to 1.1436; of the next two, *viz.* 873 and 993, that of 1 to 1.1375; and the ratio of the laſt, *viz.* 1162 and 1397, that of 1 to 1.2022. But the mean weight of the ſhot for the two and four ounces of powder, was $28\frac{1}{3}$ ounces, and $18\frac{3}{4}$ ounces; and for eight ounces of powder, $28\frac{2}{3}$ ounces, and $18\frac{3}{4}$ ounces; the reciprocal ſubduplicate ratio of the former will be that of 1 to 1.224, and of the latter that of 1 to 1.241; which are little different from the real ratios above found. The concluſions that may be deduced from theſe experiments are the following; *viz.* that powder fires almoſt inſtantaneouſly, as Mr. Robins had before obſerved; that the velocities communicated to balls of the ſame weight, with different charges, are nearly in the ſubduplicate ratio of theſe charges; and to balls of different weights, with the ſame charge, nearly in the reciprocal ſubduplicate ratio of their weights; and, therefore, when the weights of balls and charges differ, the velocities are directly as the ſquare roots of the charges, and reciprocally as the ſquare roots of the weights, nearly; ſo that it would be a great improvement to make uſe of a ſhot of a long form, or of heavier matter; as it would alſo be to diminiſh the windage; for thus one-third or more of the quantity of powder might be ſaved; and by combining theſe two laſt improvements, half the quantity of powder might be ſaved; and a ſmall gun might be made to produce the effect and execution of one two or three times its ſize, by diſcharging a ſhot of two or three times the weight of its natural ball or round ſhot. In this way a ſmall ſhip might diſcharge ſhot as heavy as thoſe of the greateſt now made uſe of. Experiments of this kind, performed with guns of various lengths, would likewiſe ſerve to determine the juſt length of cannon for ſhooting fartheſt with the ſame charge of powder. By means of ſuch experiments, properly conducted and varied, we may be able to ſolve every queſtion relating to military projectiles, except ſuch as depend on the *reſiſtance* of the air to bodies moving ſwiftly in it. See a farther account of the machinery uſed by Dr Hutton, and of his experiments, in the Phil. Tranſ. vol. lxviii. for 1778. part i. art. 3. p. 50.

In Dr. Hutton's "Tracts," (vol. i.) publiſhed in 1786, the ingenious author has detailed, at great length, another very extenſive courſe of experiments, carried on at Woolwich in the years 1783, 1784, and 1785, by order of the duke of Richmond, then maſter general of the ordnance. The principal objects of this courſe, which are undoubtedly of great importance in their relation to this ſubject, were the following:—

"1. The velocities with which balls are projected by equal charges of powder, from pieces of the ſame weight and calibre, but of different lengths.

"2. The velocities with different charges of powder, the weight and length of the gun being the ſame.

"3. The greateſt velocity due to the different lengths of guns, to be obtained by increaſing the charge as far as the reſiſtance of the piece is capable of ſuſtaining.

"4. The effect of varying the weight of the piece, every thing elſe being the ſame.

"5. The penetration of balls into blocks of wood.

"6. The ranges and times of flight of balls; to compare them with their initial velocities for determining the reſiſtance of the medium.

"7. The effect of wads;
of different degrees of ramming;
of different degrees of windage;
of different poſitions of the vent;
of chambers and trunnions, and every other circumſtance neceſſary to be known for the improvement of artillery."

All theſe objects were obtained in a very perfect and accurate manner; excepting only the article of ranges, which were not quite ſo regular and uniform as might be wiſhed. The balls, too, were moſt of them of one pound weight; but the powder was increaſed from one ounce, up till the bore was quite full; and the pendulum was from 600 to 800lb. weight. The concluſions from the whole were as follow:—

"1. That the former law, betwen the charge and velocity of ball, is again confirmed, *viz.* that the velocity is directly as the ſquare root of the weight of powder, as far as to about the charge of eight ounces: and ſo it would continue for all charges, were the guns of an indefinite length. But as the length of the charge is increaſed, and bears a more conſiderable proportion to the length of the bore, the velocity falls the more ſhort of that proportion.

"2. That the velocity of the ball increaſes with the charge to a certain point, which is peculiar to each gun, where it is greateſt; and that by farther increaſing the charge, the velocity gradually diminiſhes, till the bore is quite full of powder. That this charge for the greateſt velocity is greater as the gun is longer, but not greater however in ſo high a proportion as the length of the gun is; ſo that the part of the bore filled with powder bears a leſs proportion to the whole in the long guns, than it does in the ſhort ones; the part of the whole which is filled being indeed nearly in the reciprocal ſubduplicate ratio of the length of the empty part. And the other circumſtances are as in this table.

Table of Charges producing the greateſt Velocity.

Gun. Num.	Length of the bore.	Length filled.	Part of the whole.	Wt. of the powder.
	inches.	inches.		oz.
1	28.2	8.2	$\frac{3}{10}$	12
2	38.1	9.5	$\frac{3}{12}$	14
3	57.4	10.7	$\frac{1}{6}$	16
4	79.9	12.1	$\frac{3}{?}$	18

"3. It appears that the velocity continually increaſes as the gun is longer, though the increaſe in velocity is but very ſmall in reſpect of the increaſe in length, the velocities being in a ratio ſomewhat leſs than that of the ſquare roots of the length of the bore, but ſomewhat greater than that of the cube roots of the length, and is indeed nearly in the middle ratio between the two.

"4. The range increaſes in a much leſs ratio than the velocity, and indeed is nearly as the ſquare root of the velocity, the gun and elevation being the ſame. And when this is compared with the proportion of the velocity and length of the gun in the foregoing paragraph, we perceive that very little is gained in the range by a great increaſe in the length of the gun, the charge being the ſame. And indeed the range is nearly as the fifth root of the length of the bore; which is ſo ſmall an increaſe, as to amount only to about one-ſeventh part more range for a double length of gun.

"5. It alſo appears that the time of the ball's flight is nearly as the range; the gun and elevation being the ſame.

"6. It appears that there is no ſenſible difference cauſed

in

in the velocity or range, by varying the weight of the gun, nor by the uſe of wads, nor by different degrees of ramming, nor by firing the charge of powder in different parts of it.

"7. But a great difference in the velocity ariſes from a ſmall degree of windage. Indeed with the uſual eſtabliſhed windage only, namely, about one-twentieth of the calibre, no leſs than between one-third and one-fourth of the powder eſcapes and is loſt. And as the balls are often ſmaller than that ſize, it frequently happens that half the powder is loſt by unneceſſary windage.

"8. It appears that the reſiſting force of wood, to balls fired into it, is not conſtant. And that the depths penetrated by different velocities or charges, are nearly as the logarithms of the charges, inſtead of being as the charges themſelves, or, which is the ſame thing, as the ſquare of the velocity.

"9. Theſe, and moſt other experiments, ſhew that balls are greatly deflected from the direction they are projected in; and that ſo much as 300 or 400 yards in a range of a mile, or almoſt one-fourth of the range, which is nearly a deflection of an angle of 15 degrees.

"10. Finally, theſe experiments furniſh us with the following concomitant data, to a tolerable degree of accuracy, namely, the dimenſions and elevation of the gun, the weight and dimenſions of the powder and ſhot, with the range and time of flight, and the firſt velocity of the ball. From which it is to be hoped that the meaſure of the reſiſtance of the air to projectiles may be determined, and thereby lay the foundation for a true and practical ſyſtem of gunnery, which may be as well uſeful in ſervice as in theory."

The author has perſevered with a laudable induſtry, and with no inconſiderable ſucceſs in his experiments, keeping his main objects in view, and gradually varying them, and alſo enlarging the guns and machinery, till experiments were made with ſix-pounder guns, and pendulums of 1800 pounds weight. Among the new objects of inveſtigation, a very important one was the reſiſtance of the atmoſphere to military projectiles; for aſcertaining which, the guns were placed at many different diſtances from the pendulum, againſt which they were fired, in order to obtain the velocity loſt in paſſing through thoſe ſpaces of air. By theſe and other means, Dr. Hutton inveſtigated the reſiſtance of the air to given balls moving with all degrees of velocity, from 0 up to 2000 feet per ſecond, as well as the reſiſtance for many degrees of velocity, to planes and figures of other ſhapes, and inclined to their path in all varieties of angles; from which he has deduced general laws and formulas for all ſuch motions. See RESISTANCE.

Mr. Robins made ſeveral experiments ſimilar to thoſe of Dr. Hutton; but as muſket bullets only were employed, their ſmallneſs and change of figure by the explosion of the gunpowder have rendered them inaccurate, and the reſults different from thoſe of Dr. Hutton, above-mentioned, which were accurately made with pretty conſiderable cannon balls of iron. All theſe experiments ſufficiently evince the very great reſiſtance which the air makes to the ſwift motions of military projectiles, which in ſome caſes amounts to 22 or 30 times the weight of the ball itſelf, and which render the common rules for projectiles, deduced from the parabolic theory, of little or no uſe in real practice.

Mr. Thompſon (count Rumford) inſtituted an extenſive courſe of experiments of the ſame kind as thoſe of Mr. Robins, with muſket barrels, of which we have an account in the Phil. Tranſ. vol. lxxi. for 1781. The reſult confirmed in general the concluſions of Mr. Robins. This ingenious philoſopher, with his accuſtomed aſſiduity, purſued a hint ſuggeſted by Mr. Robins with regard to the velocity of a ball from the recoil of the pendulous gun itſelf. Mr. Robins had remarked that the effect of the exploded powder upon the recoil of the gun is the ſame, whether the gun be charged with a ball, or have no charge; and that the chord, or velocity, of recoil with the powder alone, being ſubtracted from that of the recoil when charged with both powder and ball, leaves the velocity that belongs to the ball alone. The inference, ſays count Rumford, is obvious, *viz.* that the momentum thus communicated to the gun by the ball alone, being equal to the momentum of the ball, this becomes known; and therefore being divided by the known weight of the ball, the quotient will be its velocity. The celebrated M. Euler has added many excellent diſſertations on the ſubject of gunnery, in his tranſlation of Mr. Robins's Gunnery into the German language; and the ſubject has been further improved in Brown's tranſlation of Euler's Diſſertations into Engliſh in the year 1777. Tranſ. for 1778, Edin. Phil. Tranſ. v. ii. &c.

GUNNING, PETER, in *Biography*, an Engliſh prelate, was born at How, in Kent, in the year 1613. He received the early part of his education at the free-ſchool in Canterbury, whence, at the age of fifteen, he was ſent to Clare Hall, in the univerſity of Cambridge. He was elected to a fellowſhip in 1633, and having taken his degree of M.A, he entered orders and was appointed to the cure of Little St. Mary's at Cambridge. He was very popular as a preacher, and diſtinguiſhed himſelf in the civil wars, by his zeal in defence of the king. His conduct excited the indignation of the parliamentary party, who ſubjected him to a ſhort impriſonment, and then ordered him to his college, where he was deſired to ſubſcribe "the Covenant." This he refuſed with indignation, and was accordingly ejected from the fellowſhip; when he determined to withdraw to Oxford, where, at that time, the king held his court. He had, however, a mind not eaſily daunted, and before he left Cambridge, in conjunction with Barrow and Ward, afterwards biſhops of St. Aſaph and Saliſbury, he drew up a ſpirited treatiſe againſt "the Covenant," which was afterwards publiſhed. On his arrival at Oxford, he was appointed chaplain to the New College; he alſo obtained a curacy at the diſtance of about four miles from Oxford, the duties of which he diſcharged for two years, though not without frequent interruptions and affronts, from parties of the ſoldiers belonging to the parliamentary garriſons. He was ſometimes called on to preach before the king, and for theſe ſervices he was preſented with the degree of bachelor of divinity, in the year 1646. After the ſurrender of Oxford to the parliament, he engaged as private tutor to Chriſtopher, lord Hatton, and then to ſir Francis Compton. Upon taking leave of his laſt pupil he was appointed chaplain to ſir Robert Shirley, who, as a teſtimony of reſpect for his abilities, ſettled on him an annuity of 100*l.* for life. On the death of this patron he officiated, every Sunday, in the chapel at Exeter-houſe, in London, preached and adminiſtered the ſacraments to crowded audiences, without any moleſtation, excepting that he was occaſionally ſent for and reproved

reproved by Cromwell. He would alſo, on the week days, look out for ſectaries, and diſpute with them openly in their own congregations. After the reſtoration of king Charles II. he received abundance of preferment of all kinds in the church, and in 1661, upon the ejectment of Dr. Tuckey, he was created regius profeſſor of divinity at Cambridge, and he alſo ſucceeded the ſame gentleman in the maſterſhip of St. John's college. On this occaſion it muſt be recorded to his honour, that he voluntarily ſettled on the ejected maſter a handſome annuity for life. In the year 1669, he was promoted to the ſee of Chicheſter, and in this ſituation he was very zealous in enforcing the laws for conformity; on ſome occaſions he would perſonally break up the meetings of diſſenters, and appear on the bench when non-conformiſts were to be tried for delinquency. He once gave a public challenge to the Preſbyterians, Independents, Baptiſts, and Quakers, and appointed the days for diſputations. The two former ſects he accuſed of ſchiſm and rebellion: the Baptiſts he treated with more civility, but he would ſuffer no reply. The Quakers would not ſo eaſily be put off, they addreſſed him with ſuch freedom, that he was glad to quit the pulpit and the church. Some of them followed him to his own houſe, continuing along the ſtreets obſervations which he was unwilling to hear. One, more bold than the reſt, plucked him by the ſleeve and exclaimed, "The hireling fleeth;—the hireling fleeth." In 1674, biſhop Gunning was tranſlated to the ſee of Ely, of which he proved an active ſuperintendant, and a bountiful benefactor till his death, which happened in 1684, when he was in the ſeventy-firſt year of his age. He was author of many publications which are now ſcarcely remembered. He was a zealous churchman, and was not aſhamed to own and to juſtify his principles when they were objects of perſecution, he therefore merited the honours and preferment which he enjoyed after the reſtoration. He was unweariedly active, and much of his life was ſpent in doing good. His benevolence was exerciſed in the exhibitions which he granted for the ſupport of poor ſcholars at the univerſities, and in endowments for the improvement of his ſees, the relief of the indigent and diſtreſſed; and at his death, he left the bulk of his property for the augmentation of poor vicarages.

GUNNY, a weight, is $\frac{3}{4}$ cwt. or 84lb. of cinnamon; or $1\frac{1}{4}$ cwt. = 140lb. of ſaltpetre.

GUNNISPOUR, in *Geography*, a town of Bengal; 30 miles S. of Currudeck.

GUNOLPS Fiord, a bay on the E. coaſt of Iceland, N. lat. 65° 50'.

GUNONG-TELLU, or Tomini, a large bay on the E. coaſt of the iſland of Celebes, nearly 180 miles long from E. to W. and from 50 to 90 broad. It contains ſeveral ſmall iſlands. Entrance S. lat. 6° 12'. E. long. 124°.

GUNPOWDER, a compoſition of nitre, ſulphur, and charcoal, mixed together, and uſually granulated, which eaſily takes fire, and, when fired, rareſies, or expands, with great vehemence, by means of its elaſtic force.

It is to this powder we owe all the action and effect of guns, ordnance, &c. ſo that the modern military art, fortification, &c. depend almoſt wholly upon it.

It has been eaſily diſcovered, that ſaltpetre or nitre is not indiſpenſibly neceſſary in the compoſition of gunpowder; and that it may be ſupplied by other ſubſtances. New gunpowder was ſome time ago made in France of double the ſtrength of the old, without any nitre; and Dr. Hutton tried ſome of it in 1790 at Woolwich, and found that it was about double the ſtrength of the ordinary ſort. The ſubſtitute for nitre is the like quantity of the marine acid. This, however, is an expenſive article; and it is attended with the inconvenience of taking fire and exploding, from a very ſmall degree of heat, and even without the aid of a ſpark. Some chemiſts have propoſed to ſubſtitute for nitre the oxymuriat of pot-aſh, and it has been found from experiments, ſufficiently deciſive, that gunpowder thus made exceeds with reſpect to energy of exploſion the common powder. But oxymuriats act differently from mixtures with nitre; they exert their power ſuddenly and in a very ſmall ſpace, ſo as to be very deſtructive; but in projectile force they are inferior to gunpowder. Theſe have alſo the dangerous quality of exploding with moderate friction. Some perſons, miſled by an experiment of Dr. Hales, which ſhews that burning ſulphur does not generate elaſtic air, but diminiſhes the quantity of common air, have imagined that ſulphur was an unneceſſary and even injurious ingredient of gunpowder. But M. Beaumé has found by experiments, that the force of gunpowder was nearly doubled by addition of the ſulphur. Sulphur, indeed, is not neceſſary for the exploſion of gunpowder, as the other two ingredients, well mixed, will explode; but it ſerves to diffuſe the fire inſtantaneouſly through the whole maſs of powder. The advantage, however, of uſing ſulphur ſeems, from ſome late experiments in France, applicable for increaſing the force of exploſion only to ſmall charges; but in quantities of ſome ounces, the exploſive, or at leaſt the projecting, force of powder without ſulphur is as conſiderable as it is with it.

The invention of gunpowder is aſcribed, by Polydore Virgil, to a chemiſt; who accidentally put ſome of this compoſition in a mortar, and covered it with a ſtone, when it happened to take fire, and blew up the ſtone.

Thevet ſays, the perſon here ſpoken of, was a monk of Fribourg, named Conſtantine Anelzen; but Belleforet, and other authors, with more probability, ſuppoſe him to be Bartholdus Schwartz, or the Black, who diſcovered it, as ſome ſay, about the year 1320; and the firſt uſe of it is aſcribed to the Venetians in the year 1380, during the war with the Genoeſe; and it is ſaid to have been firſt employed in a place anciently called Foſſa Clodia, now Chioggia, againſt Laurence de Medicis; and that all Italy made complaints againſt it, as a manifeſt contravention of fair warfare.

But what contradicts this account, and ſhews gunpowder to be of an older era, is, that Peter Mexia, in his Various Readings, mentions that the Moors, being beſieged in 1343 by Alphonſus XI. king of Caſtile, diſcharged a ſort of iron mortars upon them, which made a noiſe like thunder; which is ſeconded by what Don Pedro, biſhop of Leon, relates in his chronicle of king Alphonſus, who reduced Toledo, *viz.* that in a ſea-combat between the king of Tunis, and the Mooriſh king of Seville, above four hundred and fifty years ago, thoſe of Tunis had certain iron tubs or barrels, wherewith they threw thunder-bolts of fire.

Du-Cange adds, that there is mention made of gunpowder in the regiſters of the chambers of accounts in France as early as the year 1338.

Farther, it appears that our Roger Bacon knew of gunpowder near a hundred years before Schwartz was born. That excellent friar tells us, in his treatiſe "De Secretis Operibus Artis & Naturæ, & de Nullitate Magiæ," cap. 6. which is ſuppoſed by ſome to have been publiſhed at Oxford in 1216, and which was undoubtedly written before his Opus Majus, in 1267, "that from ſalt-petre, and other ingredients, we are able to make a fire that ſhall burn at what diſtance we pleaſe." Dr. Plott, in his "Hiſtory of Oxfordſhire," p. 236, &c. aſſures us, that theſe "other ingredients were explained in a MS. copy of the ſame treatiſe,

treatiſe, in the hands of Dr. G. Langbain, ſeen by Dr. Wallis, to be ſulphur and wood coal." The writer of the life of Friar Bacon, in the Biographia Britannica, vol. i. ſays, that Bacon himſelf has divulged the ſecret of this compoſition in a cypher, by tranſpoſing the letters of the two words in chap. xi. of the above cited treatiſe; where it is thus expreſſed; "ſed tamen ſalis petræ *lura mope can ubre* (*i. e.* Carbonum pulvere) et ſulphuris; et ſic facies tonitrum & corruſcationem, ſi ſcias artificium:" and from hence Bacon's biographer apprehends the words *carbonum pulvere* were transferred to the ſixth chapter of Dr. Langbain's MS. In this ſame chapter Bacon expreſsly ſays, that ſounds like thunder, and corruſcations, may be formed in the air, much more horrible than thoſe that happen naturally. He adds, that there are many ways of doing this, by which a city or an army might be deſtroyed; and he ſuppoſes that, by an artifice of this kind, Gideon defeated the Midianites with only three hundred men. (Judges, chap. vii.) There is alſo another paſſage to the ſame purpoſe, in the treatiſe "De Scientia Experimentalia." See Dr. Jebb's edition of the Opus Majus, p. 474.

Mr. Robins apprehends (ſee the preface to his Tracts), that Bacon deſcribes gunpowder not as a new compoſition, firſt propoſed by himſelf, but as the application of an old one to military purpoſes, and that it was known long before his time. Marcus Græcus, an ancient author, who probably lived about the time of the Arabian phyſician Meſue, in the beginning of the ninth century, and mentioned by him, in a treatiſe intitled "Liber Ignium," of which Dr. Mead had a MS. copy, and cited by Dr. Jebb in the preface to Bacon's Opus Majus, deſcribes two kinds of fire-works; one for flying, incloſed in a caſe or cartouche, made long and ſlender, and filled with the compoſition cloſely rammed, like our modern rocket; and the other thick and ſhort, ſtrongly tied at both ends, and half filled, reſembling our cracker; and the compoſition which he preſcribes for both is two pounds of charcoal, one pound of ſulphur, and ſix pounds of ſalt-petre, well powdered and mixed together in a ſtone mortar. See Cannon.

Mr. Dutens carries the antiquity of gunpowder much higher; and he refers to the accounts given by Virgil (Æn. lib. vi. ver. 585.), Hyginus (Fabul. 61. and 650.), Euſtathius (ad Odyſſ. λ. 234. p. 1682. l. 1.), Valerius Flaccus (lib. 1. 662.), and others, of Salmoneus' attempt to imitate thunder, preſuming from hence that he uſed a compoſition of the nature of gunpowder. He adds, that Dion Caſſius, in the "Hiſt. Rom. in Caligul." p. 662, and Johannes Antiochenus, in "Chronica," apud Peireſciana Valeſii, Paris, 1604, p. 804, report the ſame thing of Caligula. The Brachmans did the ſame, according to Themiſtius Orat. xxvii. p. 337. and alſo the Indians, whoſe practice is recorded by Philoſtratus, Vita Apol. lib. ii. cap. 33. See likewiſe lib. iii. cap. 13. Dutens's Inquiry into the Origin of the Diſcoveries attributed to the Moderns, p. 262, &c. Eng. ed. 1769.

See the preface to the Code of Gentoo Laws, 1776, where it is aſſerted, that gunpowder was known to the inhabitants of Hindooſtan far beyond all periods of inveſtigation.

Gunpowder, *Preparation of.* There are divers compoſitions of gunpowder, with reſpect to the proportions of the three ingredients, to be met with in pyrotechnical treatiſes; but the proceſs of making it up is much the ſame in all.

For ſome time after the invention of artillery, gunpowder was of a much weaker compoſition than that now uſed by us, or that deſcribed by Marcus Græcus; which was chiefly owing to the weakneſs of their firſt pieces. See Gun and Cannon.

Of 23 different compoſitions, uſed at different times, and mentioned by Tartaglia in his Queſ. and Inv. lib. iii. queſ. 5. the firſt, which was the moſt ancient, contained equal parts of nitre, ſulphur, and charcoal. When guns of modern ſtructure were introduced, gunpowder of the ſame compoſition with the preſent came alſo into uſe. The cannon powder, in the time of Tartaglia, was made of four parts of ſalt-petre, one of ſulphur, and one of charcoal; and the muſket powder of 48 parts of ſalt-petre, ſeven parts of ſulphur, and eight parts of charcoal; or of 18 parts of ſalt-petre, two parts of ſulphur, and three parts of charcoal. The cannon powder was in meal, and the muſket powder grained; and it is certain that the invention of graining powder, which is a very conſiderable advantage, is a modern improvement. (See the preface to Robins's Math. Tracts, p. 32, &c.) The modern compoſition of it is ſix parts of nitre to one of each of the other two ingredients: though Mr. Napier ſays (Tranſ. of the Iriſh Acad. vol. ii.) that he finds the ſtrength commonly to be the greateſt with the following proportions, *viz.* 3lb. of nitre, about 9 oz. of charcoal, and about 3 oz. of ſulphur: the proportion of ingredients in the powder of different nations and different manufactories has been very various. With us the government powder is the ſame for cannon and for ſmall arms: the difference conſiſting only in the ſize of the grains: but in France there have been commonly enumerated three kinds of powder, *viz.* cannon-powder, muſket-powder, and piſtol-powdes; of each of theſe again there are two ſorts, a ſtronger and a weaker; all which differences ariſe only from the various proportions.

The proportions are thus: in the ſtronger cannon-powder, to every 100 pounds of ſalt-petre, 25 pounds of ſulphur are generally allowed, with the ſame quantity of charcoal; and in the weaker cannon-powder, to every 100 pounds of ſalt-petre, 20 pounds of ſulphur, and 24 pounds of charcoal. As for the ſtronger muſket-powder, 100 pounds of ſalt-petre require 18 pounds of ſulphur, and 20 of charcoal; and in the weaker, the proportional quantities are 100 pounds of ſalt-petre, 15 of ſulphur, and 18 of charcoal. In the ſtronger piſtol-powder, 100 pounds of ſalt-petre require 12 of ſulphur, and 15 of charcoal; whereas the weaker has to 100 pounds of ſalt-petre only 10 of ſulphur, but 18 of charcoal.

Other authors preſcribe different proportions: Semienowitz, for mortars, directs 100 pounds of ſalt-petre, 25 of ſulphur, and as much of charcoal; for great guns 100 pounds of ſalt-petre, 15 of ſulphur, and 18 of charcoal; for muſkets and piſtols, 100 pounds of ſaltpetre, eight of ſulphur, and ten of charcoal. Macquer, the author of the "Dictionary of Chemiſtry," recommends 75 parts of purified nitre, 15½ parts of charcoal, and 9½ parts of ſulphur.

Miethius extols the proportion of one pound of ſalt-petre to three ounces of charcoal; or two, or two and a quarter, of ſulphur: than which, he affirms, no gunpowder can poſſibly be ſtronger. He adds, that the uſual practice of making the gunpowder weaker for mortars than guns, as in the example above, is without any foundation, and renders the expence needleſsly much greater: for whereas to load a large mortar 24 pounds of common is required, and conſequently to load it ten times, 240 pounds; he ſhews by calculation, that the ſame effect would be had by 180 pounds of the ſtrong powder.

Mr. Napier has analyſed the Chineſe powder, and found the proportions of its ingredients to be nearly 100 of nitre, 18 of charcoal, and 11 of ſulphur. It was large-grained,

not very ſtrong, but hard, well coloured, and in good preſervation. The French made many trials in 1756 at the royal manufactory of Eſſone, near Paris, for determining the beſt proportions of the component ingredients of powder. Of powder made with nitre and charcoal alone, 16 of nitre and four of charcoal yielded the ſtrongeſt, and gave a power of 9 in the eprouvette. With all theſe ingredients, 16 of nitre, four of charcoal, and one of ſulphur, raiſed the eprouvette to 15, and both a leſs and a greater quantity of ſulphur produced a ſmaller effect. Then diminiſhing the charcoal, a powder of 16 of nitre, three of charcoal, and one of ſulphur, gave a power of 17 in the eprouvette, which was the higheſt produced by any mixture. This laſt was alſo tried in the mortar eprouvette againſt the common proof powder, and was found to maintain a ſmall ſuperiority. The powder made without ſulphur in the proportions above intimated was alſo tried in the mortar eprouvette, and with the following ſingular reſult: when the charge was only two ounces, it projected a 60lb. copper ball 213 feet, and the ſtrongeſt powder with ſulphur projected it 249 feet; but in a charge of three ounces the former projected the ball 475 feet, and the latter only 472 feet: and on the other hand the great inferiority of force in the ſmaller eprouvette of the powder without ſulphur has been juſt noticed." Aikin's Dict.

When the ſeveral ingredients of gunpowder are properly prepared, mixed, and grained, in the manner already recited, if the leaſt ſpark be ſtruck thereon from a ſteel and flint, the whole will be immediately inflamed, and burſt out with extreme violence.

The effect is not hard to account for: the charcoal part of the grain whereon the ſpark falls, catching fire like tinder, the ſulphur and nitre are readily melted, and the former alſo breaks into flame; and at the ſame time the contiguous grains undergo the ſame fate. Now it is known, that ſaltpetre, when ignited, rarefies to a prodigious degree.

Sir Iſaac Newton reaſons thus on the point: the charcoal and ſulphur in gunpowder eaſily take fire, and kindle the nitre; and the ſpirit of the nitre, being thereby rarefied into vapour, ruſhes out with an exploſion much after the manner that the vapour of water ruſhes out of an æolipile; the ſulphur alſo, being volatile, is converted into vapour, and augments the exploſion: add, that the acid vapour of the ſulphur, namely, that which diſtils under a bell into oil of ſulphur, entering violently into the fixed body of the nitre, lets looſe the ſpirit of the nitre, and excites a greater fermentation, whereby the heat is farther augmented, and the fixed body of the nitre is alſo rarefied into fume; and the exploſion is thereby made more vehement and quick.

For if ſalt of tartar be mixed with gunpowder, and that mixture be warmed till it takes fire, the exploſion will be greatly more violent and quick than that of gunpowder alone, which cannot proceed from any other cauſe than the action of the vapour of gunpowder upon the ſalt of tartar, whereby that ſalt is rarefied. See *Pulvis* Fulminans.

The exploſion of gunpowder ariſes, therefore, from the violent action whereby all the mixture being quickly and vehemently heated, is rarefied and converted into fume and vapour; which vapour, by the violence of that action, becomes ſo hot as to ſhine, and appear in the form of a flame.

Dr. Ingenhouſz accounts for the effect of gunpowder, by obſerving that nitre yields by heat a ſurpriſing quantity of pure dephlogiſticated air, and charcoal a conſiderable quantity of inflammable air; the fire employed to inflame the powder extricates theſe two airs, and ſets fire to them at the inſtant of their extrication. See this theory largely explained in Phil. Tranſ. vol. lxix. part ii. art. 26.

Count Rumford (ſee Phil. Tranſ. for 1797.) is of opinion that the force of the elaſtic fluid, generated in the combuſtion of gunpowder, may be ſatisfactorily accounted for upon the ſuppoſition that its force depends ſolely on the elaſticity of watery vapour or ſteam. For this purpoſe he recurs to the experiments of M. Betancour, publiſhed at Paris, under the auſpices of the Royal Academy of Sciences, in the year 1790, which ſhew that the elaſticity of ſteam is doubled by every addition of temperature equal to 30° of Fahrenheit. From the count's reference it appears that the experiments were carried as far as 280° of that ſcale, in which caſe the preſſure was found to be equal to about four atmoſpheres. He affirms, that there ſeems to be no reaſon why the ſame law ſhould not hold in higher temperatures, and he has therefore extended his computations through 13 more terms of the geometrical ſeries, the laſt of which affords an elaſtic force equal to more than 65,000 atmoſpheres. If, indeed, the deductions from M. Betancour's experiments be admitted, the water of cryſtallization in the nitre, and the moiſture, which the charcoal may be conceived to retain, appear to be fully ſufficient to account for the exploſive force by means of ſteam only. The gaſſes produced by the exploſion of gunpowder have not been analyſed with accuracy ſince the diſcovery of all the variety of gaſſes with the baſis of carbon: but they are certainly carbonic acid, ſulphureous acid gas, and carburetted hydrogen. The reſidue is chiefly a ſulphuret of potaſh formed by a part of the ſulphur uniting with ſome of the alkali of the nitre, and hence proceeds the hepatic ſmell of a foul and damp gun-barrel. Aikin's Dict.

M. de la Hire, in the Hiſtory of the French Academy for 1702, aſcribes all the force and effect of gunpowder to the ſpring or elaſticity of the air incloſed in the ſeveral grains thereof, and in the intervals or ſpaces between the grains; the powder being kindled, ſets the ſprings of ſo many little parcels of air a playing, and dilates them all at once, whence the effect; the powder itſelf only ſerving to light a fire which may put the air in action; after which the whole is done by the air alone.

But it will appear from the experiments and obſervations of Mr. Robins, recited in the ſequel of this article, that if this air be in its natural ſtate at the time when the powder is fired, the greateſt addition its elaſticity could acquire from the flame of the exploſion would not amount to five times its uſual quantity, and, therefore, could not ſuffice for the two hundredth part of the effort, which is exerted by fired powder.

In order to underſtand the force of gunpowder, it muſt be conſidered, that whether it be fired in a vacuum or in air, it produces by its exploſion a permanent elaſtic fluid. For if a red-hot iron be included in a receiver, and the receiver be exhauſted, and the gunpowder be then let fall on the iron, the powder will take fire, and the mercurial gage will ſuddenly deſcend upon the exploſion; and though it immediately aſcends again, yet it will never riſe to the height it firſt ſtood at, but will continue depreſſed by a ſpace proportioned to the quantity of gunpowder which was let fall on the iron. By this means (firing ſmall quantities at a time) the mercurial gage may be reduced from 29½ inches to 12½. Now this experiment, which has been often repeated, proves the propoſition with reſpect to the production of a permanent elaſtic fluid in a vacuum; for the deſcent of the gage could only be effected by the preſſure of ſome new generated fluid in the receiver, balancing in part the preſſure of the external air. That this fluid, or ſome

ſome part of it at leaſt was permanent, appears from hence, that though in theſe experiments the quickſilver aſcended after the operation, yet, next day it had aſcended no higher than 22½, at which place it ſeemed to continue fixed. And that this fluid is elaſtic, is proved from the deſcent of the mercurial gage; ſince the quantity of matter contained in this fluid could not by its gravity alone have ſunk the quickſilver by the leaſt ſenſible quantity; alſo from its extending itſelf through any ſpace, however great, the experiment ſucceeding in either a large or ſmall receiver, only the larger the receiver the leſs will be the deſcent of the mercurial gage to the ſame quantity of powder; the preſſure of the generated fluid diminiſhing as its denſity diminiſhes. See Phil. Tranſ. No. 295.

The ſame production likewiſe takes place, when gunpowder is fired in the air; for if a ſmall quantity of powder be placed in the upper part of a glaſs tube, and the lower part of the tube be immerged in water, and the water be made to riſe ſo near the top, that only a ſmall portion of air is left in that part where the gunpowder is placed; if in this ſituation the communication of the upper part of the tube with the external air be cloſed, and the gunpowder be fired (which may eaſily be done by a burning-glaſs) the water will, in this experiment, deſcend on the exploſion, as the quickſilver did in the laſt, and will always continue depreſſed below the place at which it ſtood before the exploſion; and the quantity of this depreſſion will be greater, if the quantity of powder be increaſed, or the diameter of the tube be diminiſhed. From whence it is proved, that as well in air as in vacuum, the exploſion of fired powder produces a permanent elaſtic fluid. (Haukſbee, Phyſ. Mechan. Exp. p. 11.) This releaſe of real and elaſtic air from various ſubſtances, in certain circumſtances, is now a well known and inconteſtible fact. See AIR.

It alſo appears from experiment, that the elaſticity or preſſure of the fluid produced by the firing of gunpowder, *cæteris paribus*, directly as its denſity. This follows from hence, that if in the ſame receiver a double quantity of powder be let fall, the mercury will ſubſide twice as much as in the firing of a ſingle quantity. For the vapour produced from the double quantity, being contained in the ſame receiver, will be of double the denſity of that produced from the ſingle quantity; whence the elaſticity or preſſure, eſtimated by the deſcent of the mercury, being likewiſe double, the preſſure is directly as its denſity. Alſo the deſcents of the mercury, when equal quantities of powder are fired in different receivers, are reciprocally as the capacities of thoſe receivers; and, conſequently, as the denſity of the produced fluid in each.

To determine the elaſticity and quantity of this elaſtic fluid, produced from the exploſion of a given quantity of gunpowder, Mr. Robins premiſes, that the elaſticity of this fluid increaſes by heat, and diminiſhes by cold, in the ſame manner as that of the air (a fact confirmed by ſome later experiments of Mr. Dalton); and that the denſity of this fluid, and conſequently its weight, is the ſame with the weight of an equal bulk of air, having the ſame elaſticity and the ſame temperature. From theſe principles, and from the experiments by which they are eſtabliſhed, for a detail of which we muſt refer to the book itſelf, ſo often cited in theſe articles, he concludes that the fluid produced by the firing of gunpowder will be nearly $\frac{3}{770}$ of the weight of the generating gunpowder; and the ratio of the reſpective bulks of the powder, and the fluid produced from it, will be in round numbers, 1 to 244.

Count Saluce, in his Miſcell. Phil. Mathem. Soc. priv. Taurin. p. 125, makes the proportion as 1 to 222, which, he ſays, agrees with the computation of Meſſrs. Haukſbee, Amontons, and Belidor.

Hence we are certain, that any quantity of powder fired in any confined ſpace, which it adequately fills, exerts at the inſtant of its exploſion againſt the ſides of the veſſel containing it, and the bodies it impels before it, a force at leaſt 244 times greater than the elaſticity of common air, or, which is the ſame thing, than the preſſure of the atmoſphere; and this without conſidering the great addition which this force will receive from the violent degree of heat with which it is endued at that time; the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines that the elaſticity of the air is augmented, when heated to the extremeſt heat of red-hot iron, in the proportion of 796 to 194½ nearly; and ſuppoſing that the flame of fired gunpowder is not leſs hot than red-hot iron, and the elaſticity of the air, and conſequently of the fluid generated by the exploſion, being augmented by the extremity of this heat in the ratio of 194½ to 796, it follows, that if 244 be augmented in this ratio, the reſulting number, which is 999⅓, will determine how many times the elaſticity of the flame of fired powder exceeds the elaſticity of common air, ſuppoſing it to be confined in the ſame ſpace which the powder filled before it was fired.

Hence then the abſolute quantity of the preſſure exerted by gunpowder at the moment of its exploſion, may be aſſigned; for ſince the fluid then generated has an elaſticity 999⅓, or, in round numbers, 1000 times greater than common air; and ſince common air, by its elaſticity, exerts a preſſure on any given ſurface equal to the weight of the incumbent atmoſphere, with which it is in equilibrio: the preſſure exerted by fired powder, before it has dilated itſelf, is 1000 times greater than the preſſure of the atmoſphere, and, conſequently, the quantity of this force on a ſurface of an inch ſquare, amounts to above ſix tun weight; which force, however, diminiſhes, as the fluid dilates itſelf.

Though it has here been ſuppoſed, that the heat of gunpowder, when fired in any conſiderable quantity, is the ſame with iron heated to the extremity of a red heat, or to the beginning of a white heat, yet it cannot be doubted but that the fire produced in the exploſion is ſomewhat varied (like all other fires) by a greater or leſs quantity of fuel; and it may be preſumed, that according to the quantity of powder fired together, the flame may have all the different degrees from that of a languid red heat to the heat ſufficient for the vitrification of metals; but as the quantity of powder requiſite for the production of this laſt mentioned heat is certainly greater than what is ever fired together for any military purpoſe, we ſhall not be far from our ſcope, if we ſuppoſe the heat of ſuch quantities as come more frequently in uſe to be, when fired, nearly the ſame with the ſtrongeſt heat of red-hot iron; allowing a gradual augmentation to this heat in larger quantities, and diminiſhing it when the quantities are very ſmall. Prin. of Gunnery, in Robins's Math. Tracts, vol. i. p. 59, &c.

Gunpowder is ſuppoſed to explode at about 600° Fahr. but if heated to a degree juſt below that of faint redneſs, the ſulphur will moſtly burn off, leaving the nitre and charcoal unaltered.

We may obſerve, that the variations of the denſity of the atmoſphere do not any way alter the action of powder. By comparing ſeveral trials made at noon in the hotteſt ſummer ſun, with thoſe made in the freſhneſs of the morning and the evening, no certain difference could be perceived;

ceived; and it was the ſame with thoſe made in the night and in winter. Indeed, conſidering that the ſame quantity of that elaſtic fluid in which the force of powder conſiſts, is generated in a vacuum and in common air, it is difficult to conceive how this force can be affected by the greater or leſs denſity of the atmoſphere.

But the moiſture of the air has a very great influence on the force of powder; for that quantity which in a dry ſeaſon would communicate to a bullet the velocity of 1700 feet in one ſecond, will not in damp weather communicate a velocity of more than 12 or 1300 feet in a ſecond, or even leſs, if the powder be bad and negligently kept. Robins's Math. Tracts, vol. i. p. 101, &c.

This agrees with an experiment made before a committee of the Royal Society, where powder having been dried by being put into a phial placed in boiling water, threw a ball out of a mortar twice as far as the ſame quantity of powder taken out of the ſame barrel before it was dried.

Now the ranges under the ſame circumſtances of charge, elevation, &c. being as the ſquares of the velocities of the ball, theſe velocities, in this experiment, will be to each other nearly as 17 to 12, which give ranges as 289 to 144. Phil. Tranſ. N 465. p. 182, 183.

If powder be damp, ſhot made with equal quantities of it out of the ſame parcel, will differ conſiderably from each other, perhaps ten times more than if the powder was in good order. A ſmall charge ſeems to loſe a greater part of its force than a larger, each being equally damp. Another circumſtance attending damp powder is, a remarkable foulneſs in the piece, after firing, much beyond what ariſes from an equal quantity of dry powder.

That powder will imbibe moiſture from the air, and thereby increaſe in weight, is certain. A parcel of very good powder being placed on a white paper, pierced with a great number of fine holes, and held over the ſteam of hot water, the powder in half a minute was increaſed about $\frac{1}{50}$ in weight. Another parcel, continuing longer in the ſteam, was increaſed by $\frac{1}{18}$ part. That the moiſture of the atmoſphere has a like effect, appears from this, that an ounce of powder kept for ſome time in a room having a fire in it every day, being dried before the fire, loſt above $\frac{1}{150}$ part of its weight; one third of which it regained in leſs than two hours by being removed to a part of the room diſtant from the fire. And as the air is often much moiſter than when this experiment was tried, and the open air is more moiſt than a room with a fire, it cannot be doubted but that the twentieth or thirtieth part of the ſubſtance of the beſt powder is water. Now as a certain quantity of water mixed with powder will prevent its firing at all, it cannot be doubted but every degree of moiſture muſt abate the violence of the exploſion; and hence the effects of damp powder are not hard to account for.

It is to be obſerved, that the moiſture imbibed by powder does not render it leſs active when dried again. Indeed, if powder be expoſed to the greateſt damps, without any caution, or if common ſalts abound in it, as often happens through negligence in refining the nitre, the moiſture it imbibes may, in ſuch caſes, be perhaps ſufficient to diſſolve ſome part of the nitre, which is a laſting damage that no drying can retrieve. But when tolerable care is taken in preſerving powder, and the nitre it is compoſed of has been well purged from common ſalt, it will retain its force much longer than is uſually ſuppoſed; and it is ſaid that powder has been known to have been preſerved for fifty years, without any apparent damage from its age.

Some care is neceſſary in the drying of damp gunpowder; for there is a degree of heat, which, though not ſufficient to fire the powder, will yet melt the brimſtone, and deſtroy the texture of the grains. Nay, more, there is a heat with which the brimſtone will flame and burn away gradually, and yet the powder will not explode; of this any one may ſatisfy himſelf by heating a piece of iron red-hot, and then throwing a few grains of powder on it at different intervals, during the time of its cooling; for by this means he will find, that at a certain time the ſeparate grains that fall on the iron will not explode, but will burn with a ſmall blue flame for ſome ſpace of time, the grain ſtill remaining unconſumed. Indeed, when it has begun to burn in this manner, it ſometimes ends with exploding; but this more commonly happens when a number of grains lie near together; for then, though each ſeparate flame is not ſufficient to explode its reſpective grain, yet the whole fire made by them altogether grows ſtrong enough at laſt to end in a general exploſion; however, by attending to the proper temperature of the iron, and ſpreading the grain, two or three inches ſquare may be covered with a blue lambent flame, which will laſt a conſiderable time without any exploſion, and the grains afterwards will not apparently have loſt either their colour or their ſhape. Now ſince theſe grains, when the brimſtone is thus burnt or even melted out of them, will no longer act as powder; it is evident that powder may be ſpoiled by being dried with too violent a heat. Robins, ubi ſupra, p. 104, &c.

The velocity of expanſion of the flame of gunpowder, when fired in a piece of artillery, without either bullet or other body before it, is prodigious. By the experiments of the author ſo often quoted, it ſeems this velocity cannot be much leſs than 7000 feet in a ſecond. But M. Bernoulli and M. Euler ſuſpect that it is much greater; and Dr. Hutton imagines that it cannot be leſs at the moment of exploſion than four times as much. This, however, muſt be underſtood of the moſt active part of the flame. For, as was obſerved before, the elaſtic fluid, in which the activity of gunpowder conſiſts, is only $\frac{3}{10}$ of the ſubſtance of the powder, the remaining $\frac{7}{10}$ will, in the exploſion, be mixed with the elaſtic part, and will by its weight retard the activity of the exploſion; and yet they will be ſo completely united, as to move with one common motion; but the unelaſtic part will be leſs accelerated than the reſt, and ſome of it will not be carried out of the barrel, as appears by the conſiderable quantity of unctuous matter, which adheres to the inſide of all fire arms after they have been uſed. Theſe inequalities in the expanſive motion of the flame, render it impracticable to determine its velocity otherwiſe than from experiments The foundation of which determination is, that a barrel being fixed in a proper ſituation on a pendulum, ſuch as is deſcribed under the head Gunnery, and being charged with twelve penny-weight of powder, without either ball or wad, the powder being only put together by the rammer; on the diſcharge the pendulum aſcended through an arch whoſe chord was 10 or $10\frac{1}{2}$ inches.

Now if the piece be again loaded with the ſame quantity of powder rammed down by a wad of tow, weighing one penny-weight, it may be ſuppoſed that this wad, being very light, will preſently acquire that velocity, with which the elaſtic part of the fluid will expand itſelf when uncompreſſed; and it was accordingly found, that the chord of the aſcending arch was by this means augmented to twelve inches; ſo that by the additional weight of one penny-weight of matter moving with the velocity, of the ſwifteſt part of the vapour, the pendulum aſcended through an arch whoſe chord was two inches longer than before. And by calculating upon theſe facts, and the principles laid down in his book, Mr. Robins determines that the velocity with which this one penny-weight of matter moved, muſt be about

7000

7000 feet in one ſecond. It is this prodigious celerity of expanſion of the flame of fired gunpowder, which is its peculiar excellence, and the circumſtance in which it ſo eminently ſurpaſſes all other inventions, either ancient or modern, for the purpoſe of military projections: for as to the quantity of motion of theſe projectiles only, many of the warlike machines of the ancients produced this in a degree far ſurpaſſing that of our heavieſt cannon-ſhot or ſhells; but the great celerity given to theſe bodies cannot be in the leaſt approached by any other means than by the flame of powder. The reaſon of this difference is, that the ancients could by weights, or the elaſticity of ſprings and ſtretched chords, augment their powers to any degree deſired; but then each addition of power brought with it a proportional addition of matter to be moved; ſo that as the power increaſed, thoſe parts of the machine which were to communicate motion to the projectile, and were conſequently to move with it, were likewiſe increaſed; and thence it neceſſarily happened, that the action of the power was not ſolely employed in giving motion to the impelled body, but much the greateſt part of it was ſpent in accelerating thoſe parts of the machine in which the power reſided, to enable them to purſue the body to be projected with perpetual impulſe, during its whole paſſage through the extent of their activity. Hence then it came to paſs, that, though theſe ancient machines could throw enormous weights, they could project them but with ſmall degrees of celerity, compared with what we can communicate to our cannon and muſket-ſhot; whence in all operations, where theſe great velocities are uſeful, our machines are infinitely ſuperior to thoſe of antiquity; although, in more confined and ſhorter projections, theſe laſt have ſome advantage, which may yet render them worthy of the attention of thoſe military geniuſes, who have capacity enough to conſider each part of the profeſſion according to its true and genuine value, independent of the partial eſtimation of the times they live in. Ibid. p. 112.

There are ſeveral ways of proving the goodneſs of gunpowder. 1. By ſight; for if it be too black, it is too moiſt, or has too much charcoal in it; ſo alſo if rubbed upon white paper, it blackens it more than good powder does: but if it be of a kind of azure colour, ſomewhat inclining to red, it is a ſign of good powder. 2. By touching; for if in cruſhing it with your fingers' ends, the grains break eaſily, and turn into duſt, without feeling hard, it has too much charcoal in it; or if in preſſing under your fingers upon a ſmooth hard board, ſome grains feel harder than the reſt, or, as it were, dent your fingers' ends, the ſulphur is not well mixed with the nitre, and the powder is bad. And alſo by thruſting the hand into a parcel of powder, and graſping it, as if you were about to take a handful of it, you may feel if it be dry and equally grained, by its evading the graſp, and running moſtly out of the hand. 3. By burning, in which method little heaps of powder are laid on white paper three inches or more aſunder, and one of them fired: which, if it only fires all away, and that ſuddenly, and almoſt imperceptibly, without firing the reſt, and makes a ſmall thundering noiſe, and a white ſmoke ariſes in the air almoſt like a circle, the powder is good; if it leaves black marks, it has too much charcoal, or is not well burnt: if it leaves a greaſineſs, the ſulphur or nitre are not well cleanſed or ordered. Again, if two or three corns be laid on paper an inch diſtant, and fire be put to one of them, and they all fire at once, leaving no ſign behind, but a white ſmoky colour in the place, and the paper not touched, the powder is good. So alſo if fired in a man's hand, and it burns not; but if black knots appear, which burn downwards in the place where proof was made, after firing, it is not ſtrong enough, but wants nitre. The method moſt commonly followed for this purpoſe with us, ſays Mr. Robins, is to fire a ſmall heap of it on a clean board, and to attend nicely to the flame and ſmoke it produces, as likewiſe to the marks it leaves behind on the table; from all which inſtructive particulars the merit of the powder is aſcertained with great accuracy, as is pretended: but beſides this uncertain method, which how much ſoever it may be practiſed, none will undertake ſeriouſly to defend, there are, on particular occaſions, other contrivances made uſe of, all which bear ſome analogy to the common powder-triers, ſold at the ſhops: only they are more artfully fabricated, and inſtead of a ſpring they move a weight, which is a more certain and equal power.

Another method of proving gunpowder, is to take out of ſeveral barrels a meaſure, of about the ſize of a thimble, which is ſpread upon a ſheet of fine writing paper, and then fired; if the inflammation is very rapid, the ſmoke riſes perpendicularly, and the paper is neither burnt nor ſpotted, the powder is judged to be good: then two drams of the ſame powder, being exactly weighed, are put into a machine, called *eprouvette* or gunpowder prover, which, if it raiſes a weight of 24lb. to the height of $3\frac{1}{2}$ inches, it is allowed to be good.

But theſe machines, ſays Mr. Robins, though more perfect than the common powder-triers, are yet liable to great irregularities; for as they are all moved by the inſtantaneous ſtroke of the flame, and not by its continued preſſure, they do not determine the force of the fired powder with that certainty and uniformity which were to be deſired in theſe kinds of trials: and therefore, the method followed by the French, in the receiving of powders from the makers, ſeems to be much better. Their practice is thus:

They have, in each magazine, a ſmall mortar caſt with its bed, according to a determined pattern, which is the ſame throughout the kingdom: this mortar is always pointed at 45°, and it contains juſt three ounces of powder; and it is a ſtanding maxim, that no powder can be received into their ſtores, unleſs three ounces of it, placed in the chamber of this mortar, throw a ſolid ball of $7\frac{1}{2}$ inches diameter to the diſtance of at leaſt 55 French fathom. But if each barrel of powder was to be proved in this manner, the trouble of changing the mortar, &c. would be intolerable, and the delay ſo great, that no buſineſs of this kind could ever be finiſhed. The method by firing againſt a pendulum, in the manner mentioned under the head GUNNERY, ſeems a readier way; but ſtill it requires ſome nicety and time, which it were to be wiſhed could be obviated. (Robins's Mathemat. Tracts, vol. i. p. 121.) Dr. Hutton has contrived a machine for this purpoſe, which has ſeveral advantages peculiar to itſelf. It is a ſmall cannon, the bore of which is about one inch in diameter, and it is uſually charged with two ounces of powder, and with powder only, as a ball is not neceſſary, and the ſtrength of the powder is accurately ſhewn by the arc of the gun's recoil. The whole machine is ſo ſimple, eaſy, and expeditious in its uſe, that the weighing of the powder is the chief part of the trouble; and it is alſo ſo accurate and uniform, that the ſucceſſive repetitions or firings with the ſame quantity of the ſame ſort of powder, hardly ever yield a difference in the recoil of the 100th part of itſelf.

Count Rumford (ſee Phil. Tranſ. vol. lxxi.), having pointed out the inſufficiency and the defects of the eprouvettes, or powder triers, in common uſe, recommends for proving the goodneſs and ſtrength of powder, the following method: A quantity of powder being provided, which, from any previous examination or trial, is known to be of a proper degree

degree of ſtrength to ſerve as a ſtandard for the proof of other powder, a given charge of it is to be fired, with a fit bullet, in a barrel ſuſpended by two pendulous rods, (according to the method which the author had previouſly deſcribed in the ſame paper,) and the recoil is to be carefully meaſured upon the ribbon. When this experiment has been ſufficiently repeated, the mean and the extremes of the chords may be marked upon the ribbon by black lines drawn acroſs it, and the word *proof* may be written upon the middle line; or if the recoil is uniform, then the *proof mark* is to be made in that part of the ribbon to which it was conſtantly drawn out by the recoil in the different trials. The recoil, with a known charge of ſtandard powder, being thus aſcertained, and marked upon the ribbon, let an equal quantity of any other powder, (that is to be proved,) be fired in the ſame barrel, with a bullet of the ſame weight; every other circumſtance being alike; and if the ribbon is drawn out as far, or farther than the proof-mark, the powder is as good, or better than the ſtandard; but if it falls ſhort of that diſtance, it is worſe than the ſtandard, and to be rejected. For the greater the velocity is with which the bullet is impelled, the greater will be the recoil; and when the recoil is the ſame, the velocities of the bullets are equal, and the powder is of the ſame degree of ſtrength, if the quantity of the charge is the ſame. And if care is taken in proportioning the charge to the weight of the bullet, to come as near as poſſible to the medium proportion that obtains in practice, the determination of the goodneſs of gun-powder from the reſult of this experiment cannot fail to hold good in actual ſervice. The author has deſcribed his apparatus, and illuſtrated the conſtruction and uſe of it by appropriate figures. Since the charges with the ſame kind of powder are as the ſquares of the velocities of diſcharged bullets, the charge of the weaker powder muſt be to that of the ſtronger, when the velocities are equal, as V V to $v\,v$; V denoting the velocity of the bullet with the ſtronger powder, and v the velocity with the weaker, when the charges are equal, and the weight and dimenſions of the bullet are the ſame, and when they are diſcharged from the ſame piece. The weaker powder therefore is as much worſe than the ſtronger as V V is greater than $v\,v$; or the comparative goodneſs of powder, of different degrees of ſtrength, is as the ſquares of the velocities of the bullets when the charges are equal. The author, eſtimating the comparative goodneſs of government powder with that of double proof battle powder (ſee BATTLE), found, by the medium of ſeveral trials, that double proof battle powder is better than government powder in the proportion of 1.2036 to 1, or nearly of 6 to 5. But if inſtead of weighing the powder, we eſtimate the quantity of the charge by meaſurement, or the ſpace it occupies in the bore of the piece, the comparative ſtrength of battle powder will appear to be conſiderably greater, or its ſtrength will be to that of government powder nearly as 4 is to 3; for the grains of this better kind of powder being more compact and nearly of a ſpherical form, a greater weight of it will lie in any given ſpace than of government powder, which is formed more looſely, and of various and very irregular figures. Now the common price of double proof battle powder, as it is ſold by the wholeſale dealers in that commodity, is at the rate of 10*l. per cwt.* net, which is juſt two ſhillings *per* pound; while government powder is ſold at 5*l.* 5*s per cwt.*, or 1*s.* and $\frac{9}{15}$ of a penny *per* pound; but battle powder is better than government powder only in the proportion of 1.2036 to 1, or of 1*s.* 2*d.* to 1*s.* $\frac{9}{15}$ *d.*; battle powder is therefore ſold at the rate of 10*d.* per lb., or 41$\frac{2}{3}$ *per cent.* dearer than it ought to be; or thoſe who make uſe of it in preference to government powder, do it at a certain loſs of 41$\frac{2}{3}$ *per cent.* of the money that the powder coſts them.

Gunpowder is a commodity of ſuch conſequence, both in reſpect of ſpeculation, of war, and of commerce (the conſumption thereof being incredible), that it will deſerve a more particular detail. To make gunpowder duly then, regard is to be had, that the ſalt-petre be pure, and in fine large cryſtals or ſhootings; otherwiſe, it is to be purified, by taking away its fixed or common ſalt, and earthy part, thus: diſſolve ten pounds of nitre in a ſufficient quantity of fair water; ſettle, filtrate, and evaporate it in a glazed veſſel, to the diminution of half, or till a pellicle appear on it; the veſſel may then be taken off from the fire, and ſet in a cellar: in twenty-four hours the cryſtals will ſhoot, which ſeparate from the liquor; and after the like manner may the liquor be cryſtallized ſeveral times, till all the ſalt be drawn forth; this done, put it into a kettle, and that on a furnace with a moderate fire, which gradually increaſe till it begins to ſmoke, evaporate, loſe its humidity, and grow very white: it muſt be kept continually ſtirring with a ladle, for fear it ſhould return to its former figure, whereby its greaſineſs will be taken away; after that, ſo much water is to be poured into the kettle as will cover the nitre; and when it is diſſolved, and reduced to the conſiſtency of a thick liquor, it muſt be ſtirred with a ladle without intermiſſion, till all the moiſture is again evaporated, and it be reduced to a dry and white meal. See the ſequel of this article, and NITRAT *of Potaſh*.

The like regard is to be had to the ſulphur, chooſing that which is in large lumps, clear and perfectly yellow; not very hard, nor compact, but porous; nor yet too much ſhining; and if, when ſet on fire, it freely burns away all, leaving little or no reſident matter, it is a ſign of its goodneſs; ſo likewiſe, if it be preſſed between two iron plates that are hot enough to make it run, and in the running appear yellow, and that which remains of a reddiſh colour, it may be concluded to be fit for the purpoſe. But in caſe the ſame be foul and impure, it may be purified in this manner: melt the ſulphur in a large iron ladle, or pot, over a very gentle coal fire, well kindled, but not flaming; then ſcum off all that riſes on the top, and ſwims upon the ſulphur; take it preſently after from the fire, and ſtrain it through a double linen cloth, letting it paſs at leiſure; ſo will it be pure, the groſs filthy matter remaining behind in the cloth. See SULPHUR, and ſequel of the article.

For the charcoal, the third ingredient, ſuch ſhould be choſen as is large, clear, and free from knots, well burnt and cleaving. See CHARCOAL.

The charcoal of light woods has been generally employed; but M. Beaumé affirms, from experience, that the charcoals of heavy and hard woods, if they have been well made, are as fit for the purpoſe. The charcoal not only concurs with the ſulphur in ſupplying the inflammable matter, which cauſes the detonation of the nitre, but alſo conſiderably adds to the exploſive power of the detonating nitre, by the quantity of elaſtic vapour expelled during its combuſtion.

Gunpowder being a mixture of ſulphur and charcoal, which are very inflammable ſubſtances, with ſalt-petre, which in itſelf is not, if the ſalt-petre be too much in quantity, when compared with the other two, their burning may not be ſufficient to conſume the whole of the ſalt-petre; whence the fire may be leſs violent, and conſequently the powder leſs vigorous, than if ſome of the ſalt-petre was taken away, and a like quantity of the other materials were added in its ſtead. On the other hand, if the ſalt-petre in the compoſition be leſs than what the burning of the other two ſub-

ſtances

stances can easily consume, the fire will be less active than it ought to be, because it is not augmented so much as it would be if a larger quantity of salt-petre had been added to the composition.

Hence it appears, that the goodness of powder is not to be estimated only from the quantity of salt-petre contained in it, although that substance seems to be the basis of the elastic fluid, in which its force consists: for since the converting of the salt-petre into that fluid, and the elasticity of the fluid, afterwards, depend in some measure on the violence of the fire produced at the explosion, it is plain that there is a certain proportion in the mixture of the materials, which will best contribute to this purpose, and consequently to the perfection of the powder.

What this proportion is, has been ascertained by experience; and it seems to be generally agreed, that in any quantity of powder, three-fourths of it should be salt-petre, the remaining one-fourth consisting of equal quantities of sulphur and charcoal. This is the proportion followed by the French, and by most nations in Europe: we, indeed, pretend to a greater degree of nicety in our proportions; though, it is said, they do not greatly differ from what is here mentioned; nor is it certain that they are preferable: this, however, may be depended on, that no methods of proving powder, hitherto generally practised in England, could at all ascertain the difference; and other powders made with the usual proportion, are nothing inferior to our's.

But it is not the due proportion of the materials only which is necessary to the making of good powder; another circumstance, not less essential, is the mixing of them well together; if this be not effectually done, some parts of the composition will have too much salt-petre in them, and others too little; and in either case there will be a loss of strength in the powder. Robins, ubi supra, p. 119, &c.

The actual mode of making gunpowder has been described in a very satisfactory manner by Mr. Coleman, of the royal powder mills of Waltham Abbey, in the 9th volume of the Philosophical Magazine, and cited in Aikin's dictionary. The ingredients are taken in the proportions of 75 of salt-petre, 15 of charcoal, and 10 of sulphur. The salt-petre is almost wholly that which is brought from the East Indies, and is refined by solution, evaporation, and crystallization. (See NITRAT *of Potash*.) It is then fused in a moderate heat, so as to expel the water, but none of the acid. By refining, the salt-petre is freed from those deliquescent salts, which would render it damp by keeping, and thus materially deteriorate it. The sulphur is such as is imported from Italy and Sicily, which is refined by melting and skimming, and if it be impure, by sublimation. The English sulphur requires expensive processes for purification, which exclude it from our manufactures of gunpowder. The charcoal formerly used in this manufacture near London, and which is still used in many parts of the world, was prepared in the usual mode of charring wood, by forming piles of it, covering it with sods or fern, and allowing it to burn with a slow smothering flame. But an improvement has been introduced, which serves, in a great degree, to constitute the superior excellence of English powder. The wood is cut into billets, about nine inches long and inclosed in iron cylinders, placed horizontally; and thus burnt gradually to a red heat, the fire being continued till the volatile parts are completely expelled, and the wood is thus completely charred. The pyroligneous acid is, however, preserved for use, by collecting it in pipes, that pass out of the iron cylinder and dip into casks, in which the acid liquor condenses. This acid is used in calico-printing, chiefly as the basis of some of the iron liquors, and mordants for dark-coloured patterns. The wood, which, previously to charring, is barked, is generally either alder or willow, or dog-wood: but the difference of wood is said to be of no essential importance, provided that it be perfectly charred. The three ingredients above described, being duly prepared, are first separately ground into fine powder, then mixed in the requisite proportions, and afterwards committed to the mill for the thorough incorporation of their component parts. The powder-mill is a slight wooden building, with a boarded roof, so that in case of a moderate explosion, the roof may fly off without difficulty, and in the least injurious direction. Stamping-mills, which were formerly used, have been mostly set aside in our present manufactures, on account of the danger of over-heating, and the accidents attending it; and the business is now performed by two stones placed vertically, and running on a bed-stone, or trough. About 40 or 50 pounds of the mixed mass are laid upon this bed-stone, and moistened with water sufficient to reduce it, in the process of grinding, to a consistence considerably stiffer than paste, which experience ascertains to be the most eligible. The mills are worked either by water or horses. The composition, thus formed, is worked for about seven or eight hours, at least, in order to thoroughly incorporate and intermix the several ingredients, on which the quality of the powder very materially depends. The fine powder manufactured at Battle, in Sussex, is still worked in large mortars, or stamping-mills, with heavy pestles of lignum vitæ; but only a few pounds of the mass are wrought at a time. The next operation is that of "Corning," or graining; for which purpose it is sent to the "Corning-house." In this operation, which, however, is not essential to the manufacture of perfect gunpowder, and is only performed on account of the convenience of using it in grains rather than fine dust, the stiff paste is first pressed into hard lumps, and these are put into circular sieves with parchment bottoms, perforated with holes of different sizes, and fixed in a frame connected with a horizontal wheel. Each of these sieves is also furnished with a "runner," or oblate spheroid of lignum vitæ, which, being set in motion by the action of the wheel, squeezes the paste through the holes of the parchment bottom, forming grains of different sizes. The grains are then sorted, and separated from the dust by sieves of progressive dimensions. The grains are next "glazed," or hardened, and their rough edges taken off, by putting them into casks somewhat more than half full, which are fixed to the axis of a water-wheel, and by rapidly revolving, they are shaken against each other and rounded, and at the same time they receive a slight gloss or glazing. In this process much dust is separated from the grains.

The glazing is found to lessen the force of the powder from a fifth to a fourth (see Irish Transf. ubi supra); but it serves to preserve the powder from being injured by damp. When the powder has been corned, dusted, and glazed, it is dried in the "stove-house," where great care should be taken to avoid explosion. The stove-house is a square apartment, three sides of which are furnished with shelves or cases, on proper supports, arranged round the room, and the fourth contains a large cast-iron vessel, called a "gloom," which projects into the room, and is heated from the outside, so that no part of the fuel may touch the powder. For greater security against sparks by accidental friction, the glooms are covered with sheet copper, and are always cool when the powder is put in or taken out of the room. Here the grains are thoroughly dried, losing in the process what remains of the water added to the mixture in the mill, for bringing it to a working stiffness. This loss Mr. Cole-

man finds to be from three to five parts on 100 of the compoſition. The manufacture of the powder, when it is dry, is completed. The government powder for all ſorts of ordnance, as well as for ſmall arms, is uſually made at the ſame time, and always of the ſame compoſition; the difference conſiſting only in the ſize of the grains, as they are ſeparated by the reſpective ſieves. A method of drying powder by ſteam-pipes, running round and croſſing the apartment, has been ſucceſsfully tried; and thus the poſſibility of any injurious accident from over-heating is prevented. The temperature of the room, when heated in the common way by a gloom-ſtove, is always regulated by a thermometer hung in the door of the ſtoves.

The powder ſhould not be dried too haſtily, or with too great heat; for in this caſe ſome of the ſulphur ſublimes out, (which it will do at a leſs heat than that which will inflame the powder,) and then the intimate mixture of the ingredients will be deſtroyed: and beſides, the ſurface of the grain is hardened whilſt the inner part is left damp.

Mr. Coleman deduces from experiment the following inferences: *viz.* "that the ingredients of gun-powder only pulverized and mixed have but a very ſmall exploſive force: that gunpowder granulated after having been only a ſhort time in the mill, has acquired only a very ſmall portion of its ſtrength, ſo that its perfection abſolutely depends on very long continued and accurate mixture, and incorporation of the ingredients:—that the ſtrength of gunpowder does not depend on granulation, the duſt that ſeparates during this proceſs being as ſtrong as the clean grains:—that powder undried is weaker in evey ſtep of the manufacture than when dried:—and laſtly, that charcoal made in iron-cylinders, in the way already mentioned, makes much ſtronger powder than common charcoal. This laſt circumſtance is of ſo much conſequence, and is ſo fully confirmed by experience, that the charges of powder now uſed for cannon of all kinds, have been reduced one-third in quantity, when this kind of powder is employed." The barrelling of powder is uſually reſerved for dry weather, as it is of great importance to avoid moiſture.

Count Rumford (ſee Phil. Tranſ. vol. lxxi. pt. 2.) purſued the following method for determining the ſpecific gravity of gunpowder. A large glaſs bucket, with a narrow mouth, being ſuſpended to one of the arms of a very nice balance, and exactly counterpoiſed by weights put in the oppoſite ſcale, was filled firſt with government powder poured in lightly, then with the ſame powder ſhaken well together, afterwards with powder and water together, and laſtly with water alone, and in each caſe the contents of the bucket were very exactly weighed. The ſpecific gravity of gunpowder determined by theſe experiments is as follows:

Specific gravity of rain-water - -	1.000
Government powder, as it lies light in a heap, mixed with air - - -	0.836
Government powder, well ſhaken together -	0.937
The ſolid ſubſtance of the powder - -	1.745

Hence it appears, that a cubic inch of government powder ſhaken well together weighs juſt 243 grains; that a cubic inch of ſolid powder would weigh 442 grains; and conſequently, that the interſtices between the particles of the powder, as it is grained for uſe, are nearly as great as the ſpaces which theſe particles occupy. In his "Eſſays" the ſame ingenious philoſopher eſtimates the ſpecific gravity of gunpowder to be about 1.868.

To recover damaged powder, the method of the powder merchants is this; they put part of the powder on a ſail-cloth, to which they add an equal weight of what is really good; and with a ſhovel mingle it well together, dry it in the ſun, and barrel it up, keeping it in a dry and proper place.

Others again, if it be very bad, reſtore it by moiſtening it with vinegar, water, urine, or brandy; then they beat it fine, ſearce it, and to every pound of powder add an ounce, an ounce and an half, or two ounces (according as it is decayed) of melted ſalt-petre; and afterwards theſe ingredients are to be moiſtened and mixed well, ſo that nothing may be diſcerned in the compoſition; which may be known by cutting the maſs, and then they granulate it as aforeſaid.

In caſe the powder be in a manner quite ſpoiled, the only way is to extract the ſalt-petre with water, according to the uſual manner, by boiling, filtrating, evaporating, and cryſtallizing; and then, with freſh ſulphur and charcoal, to make it up anew again.

GUNPOWDER, *Laws relating to.* By an act made in the 16 C. I. c. 21, all ſubjects may make and ſell gunpowder, and bring into the kingdom ſalt-petre, brimſtone, or any other material for the making of it. The erection of powder-mills, or the keeping of powder-magazines near a town, is a nuiſance by the common law; for which an indictment or information will lie. By 12 G. III. c. 61, which reduces into one all former acts relating to the making, keeping, and carrying of gunpowder, no perſon ſhall uſe any mill or other engine for the making of gunpowder, in any place except in mills and other places where the manufacturing of gunpowder ſhall be actually carrying on at the time of the commencement of this act, or where it ſhall afterwards become lawful to carry on ſuch manufacture by licence for that purpoſe; on pain of forfeiting all gunpowder otherwiſe manufactured; and 2*s.* for each pound. Nor under the ſame penalty ſhall any perſon, for the making of gunpowder, uſe any mill or engine worked with a peſtle, commonly called a "Peſtle-mill;" nor in any mill or engine make at any one time, under any ſingle pair of mill-ſtones, any quantity of gunpowder, or materials to be made into gunpowder, exceeding 40*lb*; on pain of forfeiting all above 40*lb*., and alſo 2*s.* for each pound. This act does not extend to the powder-mills then erected in the pariſhes of Battle, Crowhurſt, Seddlecombe, and Brede, in the county of Suſſex, ſo far as relates to the making of ſuch fine fowling gunpowder only, as is known by the name of "Battle powder." No perſon ſhall dry at any one time, in any one ſtove, &c. any quantity exceeding 40 *cwt.* on pain of forfeiting all above that weight, and 2*s. per* pound. No perſon ſhall keep in any corning-houſe, drying-houſe, duſting-houſe, or other place uſed in the making of gunpowder, or in any adjoining building, (except magazines or ſtore-houſes conſtructed with ſtone or brick, and ſituated, at leaſt, 50 yards from the gunpowder mill,) any greater quantity of gunpowder than ſhall be neceſſary for the work then carrying on in ſuch houſe or other place; on pain of forfeiting all the gunpowder above ſuch neceſſary quantity, and 2*s.* for each pound. Manufacturers of gunpowder are to provide, beſides the magazines and ſtore-houſes near their mills, a good and ſufficient magazine remote from their reſpective mills, for the purpoſe of receiving and keeping all the gunpowder made at ſuch mills, which magazine ſhall be built with brick or ſtone, near the river Thames, and below Blackwall, or in ſome other convenient place to be licenſed by the juſtices; on pain of forfeiture of 25*l.* for every month, during which gunpowder ſhall be made without ſuch magazine, and 5*l.* for every day during which they ſhall neglect to remove, with due diligence, the gunpowder made at ſuch mill or adjoining magazine to the magazine ſo ſituated remote

from

from the mill. Every maker of gunpowder, who ſhall keep any charcoal within 20 yards of any mill or engine for the making of gunpowder, or of any drying, corning, or duſting-houſe, or any adjoining magazine or ſtore-houſe belonging to it, ſhall forfeit 5*l.* for every week during which ſuch charcoal ſhall be ſo kept. No perſon, being a dealer in gunpowder, ſhall keep at any one time more than 200*lb.* of gunpowder, and, not being a dealer, more than 50*lb.* in any houſe, &c. within the cities of London or Weſtminſter, or within three miles of either of them; or within any other city, borough, or market town, or one mile thereof; or within two miles of any of the king's palaces, or any of the king's magazines; or half a mile of any pariſh church; or in any other part of Great Britain, except in mills or other places which, at the commencement of this act, ſhall be uſed for the making of gunpowder; on pain of forfeiting all the gunpowder above the quantity allowed to be kept, and the barrels, and alſo 2*s.* for every pound beyond the allowed quantity: provided that it ſhall be lawful for any perſon to keep, for the uſe of any mine or colliery, any quantity, not exceeding 300*lbs.* in any magazine or warehouſe within 200 yards of ſuch mine or colliery. However, it ſhall be lawful for the juſtices in ſeſſions, from time to time, to licenſe the erecting or having ſuch mills and offices, or ſuch magazines for keeping unlimited quantities of gunpowder in places, not being within London or Weſtminſter, or any limits before deſcribed; and the juſtices, upon due application, and by due proceſs of law, which the act ſtates, may be ordered by the court of king's bench to grant ſuch licenſe. No perſon ſhall carry at any one time more than 25 barrels of gunpowder in any waggon, cart, or other carriage by land; or more than 200 barrels in any boat, barge, or veſſel by water, except in veſſels for importation or exportation; and the barrels ſhall be ſo ſecured that no part of the gunpowder ſhall be ſcattered in the paſſage; and each barrel ſhall contain no more than 100*lb.* of gunpowder; and when conveyed by land ſhall be entirely cloſed in a leathern bag, or bags commonly called ſaltpetre bag; and every carriage ſhall be covered with a complete covering of wood, painted cloth, tarpaulin, &c.; and no gunpowder ſhall be carried in any boat, &c. that hath not a cloſe deck, which ſhall be covered with raw hides or tarpaulins; on pain of forfeiture of the gunpowder and barrels, &c. which any perſon may ſeize for his own uſe on conviction of the offender. Juſtices are empowered to iſſue warrants for ſearching, in the day time, any houſe, mill, magazine, &c. or any carriage, ſhip, boat, &c. in which gunpowder is ſuſpected to be made, kept, or carried, contrary to this act; and the ſearcher may ſeize ſuch gunpowder and barrels. For ſecurity of ſhips on the river Thames, no maſter of any outward bound veſſel ſhall receive on board more than 25*lb.* of gunpowder (except for the king's ſervice) before the arrival of ſuch veſſel at or below Blackwall; and the maſter of every veſſel coming into the river Thames ſhall (except in caſe of the king's ſervice) put on ſhore in proper places all the gunpowder on board above 25*lb.*, either before the arrival of ſuch veſſel at Blackwall, or within 24 hours; on pain of forfeiting all the gunpowder above 25 pounds and barrels, and 2*s* for every pound. The proviſions of this act ſhall not extend to any mills or other buildings erected for making gunpowder in any lands belonging to his majeſty, or to the keeping of gunpowder in any of his majeſty's ſtore-houſes or magazines; or to hinder the trial of gunpowder by his majeſty's officers; or to the carriage of gunpowder to or from the king's magazines; under a ſpecial order from the board of ordnance; or to the carriage of gunpowder with forces on their march, or with the militia during their annual exerciſe, or which ſhall be ſent for the uſe of ſuch forces and militia.

GUNPOWDER, in *Agriculture*, a material employed by the farmer for the purpoſe of blaſting ſtones, &c. It has been lately found that the expence of this ſubſtance may be greatly leſſened by the mixing of a portion of quick lime with it. See BLASTING.

GUNPOWDER, in *Geography*, a river on the weſtern ſhore of Maryland, the chief branches of which unite above Joppa, and diſcharges themſelves into Cheſapeak bay, about 12 miles above Patapſco river. Its falls prevent its being navigable for more than a few miles.

GUNPOWDER *Neck*, a peninſula near the head of Cheſapeak bay, formed by Gunpowder river and Buſh river.

GUNSHOT WOUNDS receive their name from the manner in which they are produced. In *Surgery*, they are caſes which cannot be ſtudied with too great attention, the modern mode of warfare, and the martial times in which we live, making theſe injuries numerous beyond conception. As the invention (as ſome have ſaid) of gunpowder did not happen till the fourteenth century, and this ſubſtance was not applied to the projection of bodies from fire-arms till a later period, gunſhot wounds, compared with the generality of other diſeaſes and accidents, may be conſidered as forming rather a new branch of ſurgery. The ancient writers, who have left us valuable remarks on many ſurgical ſubjects, are totally ſilent on that which engages our preſent notice, and we muſt turn to the pages of very modern authors for what is to be looked upon as the beſt and moſt accurate information.

Gunſhot wounds, ſays Mr. Hunter, are made by the projection of hard obtuſe bodies, the greateſt number of which are muſket-balls; for cannon-balls, pieces of ſhells, and ſtones from ramparts in ſieges, or ſplinters of wood, &c. in ſea engagements, can hardly have their effects ranked with ſuch wounds as are made with bullets and muſket-balls. The latter caſes are thoſe which will generally demand whatever peculiarity of treatment may be required by gunſhot wounds. However, ſince cuſtom has claſſed all theſe various kinds of injury together, and the place is convenient, the neceſſary information concerning every ſort of miſchief occaſioned by bullets, cannon-balls, ſplinters, &c. will be introduced in the enſuing columns.

Mr. Hunter obſerves, that all gunſhot wounds will come within the definition of accidents. They are a recent violence committed on the body; but they often become the cauſe of, or degenerate into a thouſand complaints, which are the objects of ſurgery or phyſic, and many of which are common to accidents in general, and to many other diſeaſes. Of this kind are abſceſſes, ulcerating bones, and fiſtulæ; but ſome are peculiar to gunſhot wounds, as calculi in the bladder from the ball entering and lodging in that viſcus, and conſumption from wounds of the lungs, which, however, is a very rare occurrence.

Gunſhot wounds vary from one another according to circumſtances, the differences chiefly depending on the kind of body projected, the velocity of the body, and the nature and peculiarities of the injured parts. It has been ſtated, that the kind of body projected is principally muſket balls, and ſometimes cannon balls, and that pieces of broken ſhells and ſplinters of wood, eſpecially on board of ſhip, are the occaſion of the miſchief in other inſtances. Indeed, the effects of cannon-balls on different parts of the ſhip, either on the containing parts, as the hull, or the contained, are the principal cauſes of wounds in the ſailor; for, a cannon-ball muſt go through the timbers of the ſhip before it can do more execution than ſimply as a ball. It then becomes a ſpent ball, which ſplinters the inſide of the ſhip very conſi-

will only be leſſened; and if, beſides being inferior, and therefore incapable of ſtopping the moving body, it alſo operates in a different direction, the future line of motion will likewiſe be changed, and fly off from the point at which it meets with the reſiſtance, in a line which will form an angle with that of the original direction in which it moved.

M. Chevalier next reminds his reader, that the reſiſtance made by any ſubſtance to the motion of another will be greater or leſs, *cæteris paribus*, as the angle of incidence approaches to, or recedes from a right angle; and if it be reflected, and the motion be continued in the ſame medium, the angle of reflection will always be equal to the angle of incidence.

The reſiſtance made to a moving body, by the denſity of any medium in which it moves, will be, *cæteris paribus*, as the ſurface of the moving body preſented to that medium.

A denſe medium forms a continued reſiſtance to a body propelled with any given velocity; and, therefore, the more denſe the medium, the greater the reſiſtance, and the ſooner the original momentum will be overcome by it.

A ſhot, moving through any medium of uniform denſity, will alſo be acted on by the attraction of gravitation, ſo as to be continually changing the direction in which it moves; and (continues M. Chevalier), if it move in vacuo, or in air, it will deſcribe the curve called a parabola. The commencement of this curve does not take place at the point at which the gunpowder explodes; for, within the barrel, and to ſome diſtance beyond it, the ſhot moves forward in a right line, called *the line of the impulſe of fire*, (ſee Helſham's Lect. ii. p. 187.), which line will extend fartheſt horizontally, the leſs the angle of elevation of the piece recedes from an horizontal line. (See on this ſubject the article GUNNERY.)

The leſs of the original impulſe is left in a ſhot ſtill moving, the more liable will it be to be ſtopped, or turned out of its courſe by any given reſiſtance.

Every new reſiſtance (ſays M. Chevalier), which a ſhot in motion meets with, will operate ſo as to produce not only a diminution of its momentum but alſo a change in its direction; every freſh reſiſtance being in fact equivalent to a freſh power acting in a different line from that in which the ſhot was previouſly moving.

As a body acted on at once by two powers will not move in the direction of either, but in the diagonal of a parallelogram, of which two ſides are formed by the direction and momentum, given by each of thoſe powers reſpectively, ſo every change of impulſe, or reſiſtance, will cauſe the body to move in ſo many changes of direction, till at length its momentum is overcome and it becomes quieſcent.

A continued reſiſtance from a denſe medium will be a continued application of a power, the uniform and equable operation of which will cauſe the motion to be curvilinear, the reaſon of which is ſufficiently explained by writers on projectiles.

M. Chevalier afterwards obſerves, that a ſhot or other hard body, falling upon a ſoft one, as, for example, on adipoſe membrane, or muſcle, and ſtopping there, or lodging in it, ſtill acts in conformity to the ſame general laws, and ſtops only from the reſiſtance it meets with. If this reſiſtance be afforded only by the force of coheſion in the adipoſe membrane, or muſcle, ſo much of that coheſion is overcome as was equal to the momentum of the ſhot when it impinged againſt it; and, therefore, ſo far, and only ſo far, is its ſubſtance broken through or deſtroyed.

It is only on ſuch principles that we can explain the intricate and varied courſe and effect of balls in parts of diverſified ſtructure, conſiſting of ſubſtances differing in denſity and powers of reſiſtance. And though (continues the foregoing author) a mathematical explication of the courſe of a ball cannot be given in many caſes, this ariſes entirely from the want of data, the laws of matter being fixed and immutable. But when the data are known, as, for inſtance, the velocity and direction of the ſhot, the poſition of the patient, or of the wounded part at the time of the accident, and the ſtructure of the parts penetrated, a much more probable conjecture of the courſe of the ball may generally be formed, than if theſe circumſtances had not been regarded.

From the foregoing account, ſays M. Chevalier, we may ſee the reaſon of the concuſſion, or ſhock which is given, in many inſtances, to the whole ſyſtem by gunſhot wounds, and which is repreſented by the beſt writers on this ſubject to be often attended with grave and even alarming effects, extending not only over the injured part, but affecting the ſyſtem at large. For, ſays the preceding writer, as the reſiſtance to the ſhot is afforded, not only by the texture of the injured part, but alſo in ſome degree by the connection which this has with other parts, and with the whole body, theſe latter will likewiſe participate in the violence; and they will do it ſo much the more, in proportion as the part immediately wounded has, from its attachments, its texture, elaſticity, or importance to life, a greater connection with the ſtability, or with the functions of the reſt. Hence, a ſhot ſtriking againſt a tendon, or a bone, in one of the extremities, will produce a greater concuſſion than if it ſtruck only againſt ſofter parts. A ſhot ſtriking againſt a muſcle in action will produce more concuſſion than if it ſtruck againſt the ſame part of the ſame muſcle at reſt. And, a ſhot ſtriking the head, or wounding the liver, lungs, or inteſtinal canal, will generally bring on an inſtantaneous derangement of the whole ſyſtem, with which the functions of theſe parts are ſo cloſely connected. To all this muſt be added an alarm, which takes ſudden poſſeſſion of the mind, and is increaſed by the uncertainty of the patient about his real ſtate. Such apprehenſion the moſt determined courage is not always able to withſtand. See a Treatiſe on Gunſhot Wounds, by Thomas Chevalier, F. L. S. &c. edit. 3, part i. ſect. 7.

Gunſhot wounds are remarkably liable to be accompanied with the lodgment of foreign bodies, which are uſually of three kinds; firſt, pieces of the clothes or other things which the ball has forced before it into the wound; ſecondly, the ball itſelf; and, thirdly, looſe ſplinters of bone. The wound cannot be certainly free from extraneous bodies, unleſs the ball have ſtruck a naked part, touched no bone, and gone completely through the limb. Foreign bodies in gunſhot wounds are a common cauſe of numerous unfavourable ſymptoms, eſpecially of ſuch as violent inflammation, large abſceſſes, hemorrhages, and ſpaſmodic affections. Theſe bad conſequences are the more likely to be produced, the harder and more uneven and pointed the extraneous ſubſtances are.

When a ball ſtrikes a bone, writers in general ſtate, that the concuſſion may produce ill effects, not only in the contiguous parts, but even in thoſe which are at ſome diſtance from the wound. The inflammation and ſuppuration of the neareſt joint are in particular made mention of; and, in the Mémoires de l'Academie de Chirurgie, are ſome curious accounts of inflammations of parts very diſtant from that which was injured by the ſhot. The lungs and liver are deſcribed by authors as frequently becoming thus affected in conſequence of gunſhot wounds in a remote part of the body.

Certain kinds of gunſhot miſchief may occaſion, as ſoon

as

as the injury has happened, undeſcribable diſturbance of the conſtitution, together with loſs of the ſenſes, and derangement of all the functions of life. However, it is worthy of notice, that ſome exceedingly violent gunſhot wounds happen, without the leaſt ſuſpenſion of the mental faculties. We remember a ſailor, about one and twenty years of age, who had his whole arm, and a conſiderable part of his ſhoulder, carried away by a cannon-ſhot from a French fort in the Weſt Indies. The ſcapula had been ſo dreadfully ſhattered, that a ſurgeon of Antigua had deemed it adviſable to remove the whole of the ſplintered bone. We were informed by the ſailor, that his limb was torn from his body ſo inſtantaneouſly, that he not only retained his ſenſes, but was even for a time unconſcious of the dreadful injury which he had ſuſtained. He was preſented about a year and a half ago to the ſurgeons of St. Bartholomew's hoſpital, the caſe being remarkable on account of the total loſs of the ſcapula. Cheſelden and ſome other writers have related ſtriking examples of whole limbs being torn off, and of very large blood-veſſels being thus ſuddenly lacerated without any conſiderable hemorrhage taking place. Here we have another proof of the ſame remarkable circumſtance.

Gunſhot wounds in general do not bleed much; for torn and contuſed veſſels do not uſually pour forth much blood. It is highly deſerving of every practitioner's earneſt attention, however, that, although the peril of hemorrhage is in common caſes not conſiderable in the firſt inſtance, there is often a vaſt deal of danger on the ſcore of bleeding, at the period when the ſloughs are becoming looſe. Many and many a patient has at this time been deſtroyed by ſudden effuſion of blood, in conſequence of no meaſures having been prepared for its ſuppreſſion. Surgeons cannot be too much on their guard againſt bleeding, from the ſixth to the tenth, or twelfth day, whenever the nature of the wound renders it poſſible, or probable, that the ſide of any large blood-veſſel has been killed by the paſſage of the ball. Notwithſtanding not a drop of blood may iſſue from the aperture of the injury, on the firſt occurrence of the accident, ſome internal ſlough may in a few days ſeparate, and give riſe to ſuch bleeding, as muſt prove fatal, unleſs immediately ſtopped. Hence nothing can be more judicious, when there is reaſon to apprehend this dangerous event, than to leave ſome vigilant and intelligent attendant continually with the patient, and when circumſtances will permit, to have a ſlack tourniquet put round the limb, ready to be tightened in an inſtant. The patient, or nurſe, may be directed how to tighten the band, in caſe of neceſſity.

The moderns no longer conſider gunſhot wounds as being either injuries of a ſpecific nature, or caſes complicated with the lodgment of any poiſonous matter in the part. Nor is it now ſuppoſed, that, in ordinary inſtances, the heat of the ball is the occaſion of any of the extenſive miſchief which is ſo frequently obſerved. The ſeverity of many of theſe caſes is more rationally imputed to the violent manner in which the ball contuſes and lacerates the fibres among which it paſſes. The parts immediately ſurrounding the courſe of the ball are, in fact, very frequently killed, and muſt be thrown off in the form of a ſlough before the wound can heal. Thus ſuppuration is often rendered unavoidable. The violence inflicted is alſo frequently a cauſe of extenſive inflammations, abſceſſes, and fever, and, in too many inſtances, of gangrene and death. Gunſhot wounds of the head, cheſt, and abdomen are in general highly dangerous, on account of the important organs and viſcera contained in thoſe parts of the body. However, the degree of danger will always greatly depend on the violence, depth, and direction of the ball; for, when the ſhot only grazes the ſkin in any ſituation, or only runs ſuperficially under it, the peril is very different from what it is when the ſkull is fractured, the brain injured, the ſternum broken, and lungs wounded; or the bowels ſhot through.

We ſhall next proceed to ſpeak of the treatment of gunſhot wounds.

Before the period when Mr. Hunter wrote on the preſent ſubject, it was always the cuſtom to open the orifice of every wound made by a muſket-ball immediately, or as ſoon after the accident as poſſible. So much was this practice recommended, that no diſcrimination was made between one gunſhot wound and another. Mr. Hunter obſerves that this appears to have ariſen and been continued from an opinion that gunſhot wounds had ſomething peculiar in them, of courſe were different from all other wounds, and that their peculiarity was removed by the opening. That great ſurgeon, however, could not diſcern any ſuch peculiarity. He thought that the moſt probable way of accounting for the firſt introduction of this practice, is from the wound in general being ſmall, and nearly of a ſize from one end to the other. Alſo the frequency of extraneous bodies being forced into theſe wounds by the ball, and the common circumſtance of the ball itſelf being lodged in the part, might have had a ſhare in giving riſe to the method. For the way in which theſe wounds are made is by the introduction of an extraneous body, which is left in the part if it has not made its way through, and which makes a lodgment for itſelf, often carrying before it clothes, and even ſome of the ſubſtance of the wounded part, ſuch as the ſkin, &c. Theſe things muſt at firſt have ſuggeſted the immediate neceſſity of ſearching after the extraneous bodies; while, in general, the impoſſibility of finding them, and even of extracting them when found, without dilatation, firſt led practitioners to think of enlarging the mouths of the wounds by an inciſion. Experience, however, gradually occaſioned a partial alteration in this practice, and ſurgeons loſt a great deal of their anxiety to ſearch after the extraneous bodies; for they found that it was more frequently impoſſible to find them than was at firſt imagined; that when found, it was not poſſible to extract them; that they were afterwards brought to the ſkin by the parts themſelves; and that ſuch as could not be brought to the external ſurface in this way occaſioned little or no future trouble, as balls, &c. Yet it is ſomewhat ſurpriſing that the practice was only altered inaſmuch as related to the attempt to extract the extraneous bodies: for, after experience had ſhewn the general impoſſibility of extracting theſe in the firſt inſtance, the unneceſſary cuſtom of dilating the mouth of the wound was not diſcontinued, though the endeavour to extract the ball had been abandoned.

The circumſtance of gunſhot wounds being contuſed, obliges moſt of them to ſuppurate, becauſe there is more or leſs ſlough to be thrown off, eſpecially at the orifice made by the entrance of the ball. For this reaſon there muſt be a freer paſſage for the matter, or any other extraneous ſubſtance, than in another wound of equal ſize, made with a clean cutting inſtrument, even if not allowed to heal by the firſt intention.

There being no peculiarity in gunſhot wounds, Mr. Hunter was of opinion that the plan of dilating them, as a general one, ought to be rejected, were it only for this reaſon, that few gunſhot wounds are alike, and therefore the ſame practice cannot apply to all. Among other remarks againſt this method of treatment, it is repreſented by this celebrated ſurgeon, that to enlarge wounds, ſimply as wounds, is contrary to all the rules of ſurgery, founded on

our

our knowledge of the animal economy. No wound, let it be ever ſo ſmall, ſhould be made larger, excepting when preparatory to ſomething elſe, and when the caſe muſt be of a complicated kind, and require particular treatment accordingly. It ſhould not be opened, becauſe it is a wound; but becauſe there is ſomething neceſſary to be done, which cannot be executed unleſs the wound is enlarged.

This, ſays Mr. Hunter, is common ſurgery, and ought alſo to be military ſurgery, reſpecting gunſhot wounds. He owns that it would be abſurd for any one to ſuppoſe that there is never occaſion to dilate gunſhot wounds at all; but, at the ſame time, he contends, that there are very few inſtances in which ſuch proceeding is neceſſary. He explains that it will be impoſſible to determine, by any general deſcription, what caſes ought to be opened and what ought not. When once the ſurgeon is maſter of the arguments on both ſides, this part of the treatment muſt be in a great meaſure regulated by his own diſcretion. Some general rules may be given, with regard to the more ſimple caſes; but with regard to the more complicated, the particular circumſtances of each caſe are the only guide, and the treatment muſt be adapted to the received principles of ſurgery.

Mr. Hunter firſt endeavours to give an idea of the wound, which would receive no benefit from being dilated. He notices, that if a ball paſſes through a fleſhy part, ſuch as the thick portion of the thigh, where no bone has been hurt, he can perceive no reaſon for dilating the wound, becauſe no purpoſe can be anſwered by it. If the ball does not paſs through, and cannot be found, the dilatation can alſo be of no ſervice.

Suppoſing it ſhould be objected that the opening in the ſkin is too ſmall to allow the ſloughs, &c. to eſcape, Mr. Hunter believes that this objection is in general deſtitute of foundation. He obſerves, that, in all caſes of wounds, the ſkin is kept open by its own elaſticity, a property which muſcles and many other parts do not poſſeſs. The opening made by the ball is uſually much larger than what is occaſioned by pointed inſtruments; for beſides the circular ſlough, there is often a piece of ſkin carried in before the ball, eſpecially when the latter has moved with conſiderable velocity, ſo that, in ſuch caſes, there is really a greater loſs of ſubſtance. Therefore, whatever matter or extraneous body may be preſent, will find a free paſſage out as ſoon as it arrives at the ſkin. Nor does the wound in the ſkin in general heal ſooner than the bottom; and, indeed, adds Mr. Hunter, in many caſes it does not heal ſo ſoon, becauſe the ſkin is generally the part that has ſuffered moſt.

Mr. Hunter acknowledges that the ſkin ſometimes heals firſt, but he found this to happen as often when openings had been made as when they had not. This he refers to circumſtances or peculiarities; ſuch as the bottom of the wound being at a conſiderable diſtance, containing extraneous bodies, having no diſpoſition to heal, and tending to a fiſtula. He noticed in practice, that in ſuch caſes the wound or opening, made by the ſurgeon, generally ſkinned to a ſmall hole before the bottom of the wound was cloſed, which brought things into the ſame ſtate as they would have been in had no dilatation at all been made, eſpecially ſuppoſing ſome extraneous bodies ſtill to remain. An extraneous body cauſes and keeps up the ſecretion of matter, or rather keeps up the diſeaſe at the bottom of the wound, by which means the healing diſpoſition of its mouth is in ſome degree deſtroyed. Mr. Hunter calls the attention of his reader to a caſe of the latter deſcription. Suppoſe a wound made with a ball, and incapable of healing in ſix months, becauſe the extraneous bodies, &c. cannot be extracted or work out ſooner, or ſome other circumſtance prevents a more ſpeedy cure. Open that wound as freely as may be thought neceſſary; yet Mr. Hunter maintains that in a month's time it will be in the ſame ſtate as a ſimilar wound that has not been opened; ſo that the whole advantage, if there is any at all, muſt be previouſly to this ſtate. It is very ſeldom, however, that any thing of conſequence can be done in that time, becauſe the extraneous bodies do not come out ſo readily at firſt as they do at laſt, for the inflammation and tumefaction, which extend beyond the opening, generally confine ſuch foreign ſubſtances. Hence, if the wound is opened on their account at firſt, it ought to be kept open till the very laſt. Upon the ſame principle this excellent ſurgeon contends, that opening a gunſhot wound at firſt, on account of extraneous bodies, cannot be of ſo much ſervice as the performance of the ſame operation ſome time afterwards; for the ſuppuration, with its leading cauſes, *viz.* inflammation and ſloughing all along the paſſage of the ball, makes the paſſage itſelf much more determined and more eaſily followed; and the courſe of the wound not being ſo at the beginning, is the reaſon why few extraneous bodies can ever be extracted at that time, except what are ſuperficial, ſmall, and looſe.

When the extraneous bodies are broken bones, they are ſeldom entirely detached, and therefore muſt become looſe before they can come away. In many caſes, alſo, the bones are rendered dead, either by the blow or by being expoſed. Such bones muſt exfoliate, and this requires time.

Mr. Hunter next proceeds to remark, that a reaſon given for opening gunſhot wounds, is, that it takes off the tenſion ariſing from the inflammation, and gives the part liberty. This, ſays he, would be very good practice, if tenſion or inflammation were not a conſequence of wounds; or if it could be proved that the effects of dilating a part already wounded are very different, if not quite the reverſe of thoſe of the firſt wound. But ſince enlarging the wound muſt always be conſidered as an extenſion of the firſt miſchief, we muſt infer that it produces an increaſe of the effects ariſing from ſuch miſchief. Therefore this practice is contradictory to common ſenſe and common obſervation.

They are principally compound wounds, obſerves Mr. Hunter, which require ſurgical operations, and the following precautions are laid down as neceſſary in theſe caſes.

As the dilatation of gunſhot wounds is a violence, it will be proper to conſider well what relief can be given by ſuch an operation, whether without it more miſchief would enſue, and what is the beſt time for putting the proceeding into execution.

To make this ſtep adviſable, we muſt have ſome other views than ſuch as have been objected to; we muſt ſee plainly ſomething to be done for the relief of the patient by making the opening; we muſt know that the benefit cannot be procured without it, and if not procured, that the part cannot heal, and the patient is likely to loſe his life.

Firſt, if the wound ſhould be a ſlight one, and require opening, the operation will be beſt at the beginning before inflammation comes on. The inflammation, in conſequence both of the accident and dilatation, will then only be ſlight. However, in theſe leſs ſerious caſes, dilatation will never be neceſſary, except to allow of the extraction of ſome extraneous body which is near. But if the wound is a conſiderable one, and it ſhould appear upon conſideration that you cannot relieve

relieve immediately any particular part, or the conſtitution, then you gain nothing by opening immediately, but only increaſe the inflammation; and, in ſome caſes, the inflammation ariſing from the accident and opening together may be too much for the patient. Under this laſt circumſtance, it will be more adviſable to wait till the firſt inflammation ceaſes, by which means, the patient will ſtand a much better chance of a cure, the inflammations being divided. It is poſſible, however, that the inflammation may ariſe from ſome cauſe which could be removed by opening the wound. For inſtance, a ball, or broken bone, preſſing upon ſome part, whoſe actions are eſſential to the life of the part, or of the whole body, or ſome large artery, nerve, or vital part.

Secondly, when an artery is wounded, and the patient is likely to become too weak, or die from loſs of blood, the veſſel ought undoubtedly to be tied, and, moſt probably, this cannot be done without previouſly opening the external parts, and often freely.

Thirdly, in a wound of the head, when there is reaſon to ſuſpect a fracture of the ſkull, it may be neceſſary to open the ſcalp.

Fourthly, when there are in any part of the body fractured bones, which can be immediately extracted with advantage, and which would do much miſchief if left, the caſe is to be regarded as a compound fracture wherever it is. It makes no difference in the treatment, whether the wound in the ſkin was made by a ball or the bone itſelf, at leaſt where the compound fracture is allowed to ſuppurate; for there is often a poſſibility of treating a compound fracture as a ſimple one, a thing which gun-ſhot fractures will ſeldom admit of. The caſes, however, are very ſimilar, when ſuppuration cannot be avoided. Inſtances, indeed, ſays Mr. Hunter, have been known, in which a fracture of the thigh bone, occaſioned by a ball, has healed in the ſame way as a compound ſimple fracture, by which term, we conceive, is implied a compound fracture, which admits of being cured like a ſimple one, without ſuppuration.

Fifthly, where there is ſome extraneous body which can eaſily be extracted, and the miſchief from delay is likely to exceed that reſulting from the dilatation, the operation is indicated.

Sixthly, when ſome internal part is miſplaced, and can be put at once into its natural poſition again, it may be proper to dilate the wound, as in wounds of the belly, attended with a protruſion of ſome of the viſcera, where it is neceſſary to perform gaſtroraphe. In this caſe, the operation is to be done in the ſame manner as if the accident aroſe from any other cauſe; but Mr. Hunter obſerves, that the treatment ſhould be different; for gunſhot caſes cannot heal by the firſt intention, on account of the ſlough which is to enſue. See GASTRORAPHE.

Seventhly, when ſome vital part is preſſed, ſo that its functions are loſt, or much impaired, as will often happen in caſes of fractured ſkull, fractures of the ribs, ſternum, &c. an enlargement of the wound may be neceſſary. In ſhort, the operation is proper, ſays Mr. Hunter, when any thing can be done to the part for the preſent, or future relief of the patient by making the opening.

When none of the foregoing circumſtances exiſt, this great ſurgeon thinks, that the practitioner ought to be quiet. He ſtates, that when balls enter the cavity of the abdomen, or thorax, the wounds need not be dilated, except ſomething elſe is neceſſary to be done to the contained parts; for it is impoſſible to follow the ball.

When balls enter any part where they cannot be followed, as into the bones of the face, no dilatation of the wound in the ſkin is requiſite, ſince the operation can do no good to the reſt of the wound, which is a bony canal.

At preſent, ſurgeons do not give themſelves ſo much trouble about the balls, nor often dilate the wound on their account. When the wound is dilated, they do not ſearch much after them, which ſhews that the opening is not neceſſary, or at leaſt, that it is not made on account of extraneous bodies.

Such practice, obſerves Mr. Hunter, has ariſen from experience; for it has been found, that balls, when obliged to be left, have ſeldom or never done any harm when at reſt, and not ſituated in a vital part. Balls have been known to lie in the body for years, and are frequently never found at all, and yet the perſon experiences no inconvenience.

The difficulty of finding balls, and of extracting them when found, led to the information that balls were not very apt to promote inflammation.

The ball cannot readily be found at firſt, becauſe the parts are only torn and divided, without any loſs of ſubſtance before the ſlough comes away. Hence the parts collapſe and fall into their places again, ſo as to make it difficult to paſs any thing in the direction of the ball, or even to know its direction. This difficulty is increaſed by the winding courſe which a ball takes, in conſequence of being turned aſide by ſome reſiſting body.

The courſe of a ball, however, may eaſily be traced when it is not perpendicular, but runs obliquely, and not more deeply than an inch or ſo; for the ſkin over the paſſage of the ſhot is generally marked by a reddiſh line. See Hunter on Gunſhot Wounds.

After what has been ſaid, it muſt be manifeſt to every impartial reader, that the advantage of dilating gunſhot wounds has been immenſely exaggerated. The abſurdity of dilating all of them muſt ſtrike every man of moderate underſtanding, on reflecting that many of theſe caſes are widely different from others, and conſequently cannot require the ſame ſort of treatment. When the courſe of a ball lies in ſoft parts, and has neither injured a bone, nor a conſiderable blood-veſſel, whether the wound has one or two openings, the plan of dilating it can generally be productive of no good. We have ſtated, that in gunſhot wounds, the opening in the ſkin is larger than that of a ſtab, becauſe there is an actual loſs of ſubſtance in the integuments, the part of which, firſt ſtruck by the ball, is uſually driven into the wound. By the ſeparation of the ſloughs, the canal of the wound is rendered ſtill larger, ſo that not only matter, but any extraneous ſubſtances, can find a ready eſcape outward. Inciſions alſo generally ſoon cloſe again, and the wound becomes, in a few days, in the ſame condition, as if no dilatation had been made.

However, there can be no doubt, that it is proper to extract at firſt every foreign body, which can be taken away without too much irritation; for the lodgment of extraneous ſubſtances frequently exaſperates the inflammatory ſymptoms, brings on pain and conſtitutional diſturbance, and produces large abſceſſes. At the ſame time, the practitioner ought to remember, that ſearching after foreign bodies often occaſions immenſe irritation of the wounded part, and that very frequently they cannot be extracted when felt, owing to the firm and deep manner in which they are lodged. When the wound becomes widened by the ſeparation of the ſloughs, the foreign bodies commonly grow looſe, and therefore admit of being removed with more eaſe. Alſo, after the wound has ſeparated, ſuch extraneous ſubſtances as happen to be deeply lodged, generally come nearer to the opening in the ſkin, and can be taken out with greater facility. It ſhould likewiſe

likewife be recollected, that foreign bodies, of fmooth figure, have often been known to remain, without the leaft inconvenience, in parts from which there was no poffibility of extracting them. The furgeon, therefore will, for the moft part, act wifely, who endeavours at firft to extract only fuch extraneous bodies as happen to be fituated near the external opening, and are loofe and removeable without much irritation. In fhort, it may be laid down as a maxim, in the treatment of gunfhot wounds, that if the dilatation of them, for the purpofe of extracting foreign bodies, is lefs likely to aggravate the inflammation, than the prefence of thofe bodies, then it is highly judicious to put it into execution; or, in other words, when the united inflammation, from the injury itfelf, and the irritation of dilating it and removing the extraneous fubftances, is likely to be lefs than what would arife from the injury and lodgment of the foreign bodies, incifions are warrantable for the removal of the latter.

In a foregoing column of this article, fome notice has been taken of the laws which govern bodies in motion, and ferve as an explanation of the ftrange courfes which balls frequently take, after entering the fubftance of the human body. It may be proper to add a few more obfervations on this fubject. The regularity of the paffage of a ball will, in general, be in proportion to its velocity, and the want of refiftance; for, fays Mr. Hunter, balls are turned afide in an inverfe proportion to the force with which they move. Hence they feldom take a ftraight courfe; for if they are fpent balls, the foft parts alone are capable of turning them; and if they move with confiderable velocity, they are likely to hit fome bone obliquely, by which they will alfo be turned afide. Any thing which prefents the leaft oblique refiftance to a ball, throws it out of its direct courfe. We have a proof of the eafe with which balls are obliquely thrown off, in thofe frequent cafes, in which a ball, entering the fkin of the breaft obliquely, afterwards paffes almoft round the whole body under the integuments. Here the fkin is ftrong enough to hinder the ball from coming out again, which therefore turns inward; but meeting with the ribs, it is again turned out to the integuments, and fo on alternately, as long as it has force enough to go on.

Sometimes, however, the ball goes a little way after piercing the fkin, and then meets with fome hard fubftance, fuch as a rib, on the fide next the centre of the body, by which new refiftance its courfe is directed outward, and it pierces the fkin a fecond time. But here the velocity of the ball muft be confiderable.

Mr. Hunter notices his having feen a ball pafs in at one fide of the fhin-bone, and run acrofs it under the fkin, without either cutting the fkin acrofs or hurting the bone. The velocity in this inftance could not have been great, for there is not fufficient room between thefe two parts in a natural ftate for a ball to pafs; but the ball, after it had got under the fkin, where there was room for it to cover itfelf, then came againft the tibia which threw it outwards. The integuments counteracting were next only raifed from the tibia, fo that the ball paffed on between the flefh and the bone. Had the ball been moving with fufficient velocity, it would either have cut the fkin acrofs, or taken a piece out of the bone, and perhaps effected both kinds of injury.

The direction of a fhot is alfo rendered uncertain by the wounded parts not continuing in the pofture in which they were at the time of the accident. For inftance, in confequence of the patients arm having been ftretched out in a horizontal pofition, when he was fhot, the ball may have entered on one fide of the biceps mufcle, gone ftraight on, and come out clofe to the fpinous proceffes of the vertebræ between the fcapulæ. This happened in a cafe which Mr. Hunter has made mention of in his treatife on gunfhot wounds.

There are two or three more circumftances, relating to the dilatation of gunfhot wounds, deferving attention. When the ball paffes a conſiderable way under the fkin, and near to it, Mr. Hunter is an advocate for making an opening midway between the two orifices occafioned by the ball, efpecially when they are at a great diftance from each other. The object of this practice is to facilitate the preſent, or future extraction of fplinters of bone, and other extraneous fubftances. When an opening is not made, an abfcefs frequently forms between the two apertures made by the ball, and though it fometimes anfwers the purpofe as well, it is not always proper to wait for fuch an event to take place.

When the ball runs a little way along under the fkin and comes out again, it may be beft to lay open the wound as far as it extends. The reafon which Mr. Hunter affigns for this advice, is that the fkin does not fo readily unite with the parts underneath, as mufcles do with one another.

In certain cafes the ball enters and paffes on, till it comes into contact with the integuments of another part, where it may eafily be felt. Ought fuch a ball to be cut out? Mr. Hunter thought, that if the fkin was bruifed by the ball coming againft it, and likely to flough, there was no reafon againft making an opening, becaufe the part is to be looked upon as dead, and not more inflammation will arife from the opening made with a knife, than from one made by the flough. However, he does not impute much utility to making an incifion, as the flough will come away, and the ball efcape of itfelf.

When the ball is only to be felt, and the fkin quite found, Mr. Hunter advifes us to let the extraneous body alone, till the wound, made by its entrance, has inflamed and fuppurated. His chief reafons for this plan are: firft, becaufe moft wounds get well when the ball is left in, excepting it has done other mifchief, befides fimply paffing through the foft parts, and very little inflammation attends that portion of the wound where the ball lodges, but a great deal where it made its entrance. Secondly, when a ball paffes through and through, two inflammations arife, one at the entrance, another at the exit of the ball. When the velocity indeed has been very great, the inflammation is continued through and through. When the ball makes its exit, the inflammation extends further along the canal, than when the wound in another cafe is healed up to the ball, which is afterwards cut out. When the ball is extracted in the firft inftance by a counter-opening, the fame kind of inflammation attacks the place of the incifion, as makes its appearance about the entrance of the ball.

With regard to the moft eligible fort of inftrument, for the extraction of balls and other extraneous fubftances from gunfhot wounds, the fingers are better than any thing in a great number of inftances. When forceps are employed, they ought not to be of a large, clumfy conftruction, and occafionally both ftraight and curved ones will be found moft advantageous. Mr. Chevalier has given in his treatife, an engraving of fome different bullet forceps, which feem to obtain approbation among military furgeons, and are now put in all the army inftrument chefts.

Befides the indifcriminate plan of dilating every gunfhot wound without exception, there is another common cuftom, which appears equally deferving of cenfure, and this is to poke probes, and other inftruments into the wound, without having any thing in view, except the mere gratification of

curiosity. We do not mean to say, that the introduction of a probe into the wound is always wrong; if there is reason to suspect that any extraneous substance lies in the part, and that it can be extracted without too much irritation, the surgeon is undoubtedly justified in probing the wound, in order to obtain the requisite information concerning the nature and situation of the foreign body. Learning the direction and depth of a gunshot wound, by means of a probe, may also be frequently right, though in general the knowledge thus acquired does not produce the smallest difference in the mode of treatment. However, it must be confessed, that there is always some advantage in being aware of the direction and depth of the wound; because, when we have cause to apprehend that the ball has passed near any large artery, or injured any particular viscus, or that it has penetrated to a considerable depth, we can be more upon our guard against the consequences. We may prevent a fatal hemorrhage by our vigilance and precautions during the first ten days, or we may be so careful in having recourse to every thing that is antiphlogistic, without loss of time, as to prevent such a degree of inflammation in the injured parts, as would be the destruction of the patient. Upon these principles alone is the probing of a gunshot wound justifiable and proper.

Gunshot wounds, as we have remarked, seldom admit of being healed by the first intention; they must first throw off their sloughs, and suppuration is to be followed by the production of granulations. There is little danger of the external opening healing up too soon, that is to say, while matter is forming within, and before sloughs and loose extraneous substances, more deeply situated, are discharged. The parts surrounding the entrance of the ball are always more injured, and consequently less capable of healing than the deeper part of the wound. Therefore, the method of cramming the mouth of the injury with tents, and dossils of lint, with a view of keeping it from closing, is for the most part totally unnecessary, and being productive of a vast deal of irritation, exceedingly hurtful. The dressings for gunshot wounds should generally be such as are unirritating, light, and superficial. A pledget of some simple salve, covered by an emollient poultice, is commonly more eligible than stuffing the wound with dry lint, or applying any stimulating balsam or lotion. The poultice and dressing should be changed three or four times a day, in case the discharge is large; and the former application ought never to be allowed to remain on the part till it has become stiff and hard, whatever may be the state of the case. There can be no allowable excuse for irritating a gunshot wound, by pretending, that certain applications are necessary to stop the bleeding. Gunshot wounds will not bleed in the first instance, unless very large vessels, such as ought to be tied, are injured, and there is not invariably an hemorrhage in this circumstance, torn and contused vessels not having much disposition to pour out any considerable quantity of blood.

In all cases of gunshot wounds, the violence committed on the living parts must give birth to inflammation. When this can be kept within moderate bounds, the patient will generally do well; but, when it rises too high, becomes too extensive, and occasions large abscesses and gangrenous mischief, the event of the case must be regarded as extremely doubtful. Hence, one indication invariably presents itself, which is to keep down inflammation by those means which experience has ascertained to be the best calculated for the purpose, and which consist of general and topical bleeding, purging, low diet, and quietude.

The following extract from Mr. Hunter's treatise on gunshot wounds, relative to the subject of bleeding, we regard as truly practical, and worthy of its great and immortal author. "Bleeding," says he, "is recommended in gunshot wounds, and in such a manner as if of more service in them than wounds in general; but, I do not see this necessity more than in other wounds, that have done the same mischief, and where the same inflammation and other consequences are expected.

"Bleeding is certainly to be used here as in all wounds, where there is a strong and full habit, and where we expect considerable inflammation and symptomatic fever; but if it is such a gunshot wound as not to produce considerable effects, either local or constitutional, I would not bleed merely because it is a gunshot wound; and, from what I have seen, I think, that inflammation, &c. does not run so high in these wounds as I should have at first expected. I believe this is the case with all contused wounds, where death in the part is a consequence; a contused wound is somewhat similar to the effects of a caustic; for while the separation of the dead part is forming, the suppurative inflammation is retarded, and therefore not so violent. But this can only be said of those wounds which are not complicated with any other injury, except what was produced by the balls passing through soft part; for if a bone is broken, it will inflame like any other compound fracture.

"It is often of service, in the time of inflammation, to bleed in the part with leeches, or by punctures with a lancet. This helps to empty the vessels of the part, to lessen the inflammation sooner, and of course to promote suppuration. But I must own that bleeding must be used with great caution, where inflammation and fever run very high; for, to reduce the patient equal to the action at the time, (which, whether an increased action, or an acquired one, is only temporary,) will be reducing him often too much for the constitution to support life when this action ceases; for the very worst thing that can happen is the patient being reduced too low. We often afterwards find more difficulty in keeping up with cordials, bark, &c. than we find in lowering; and we may avail ourselves of observing those who have lost considerable quantities of blood from the accident, which is always immediate; and we find, too, that a second bleeding, by some other accident, although very small in quantity, often destroys our patient very quickly. But this will in a great measure depend upon the seat of the injury; for in cases of great violence, done to some parts of our body, bleeding answers better than in others, because the symptoms of dissolution, and dissolution itself, come on sooner from mischief done to some parts, than when it is done to others.

"A man will bear bleeding better after an amputation of the arm than leg; better after a compound fracture of the arm than leg; he will bear bleeding better after an injury done to the head, chest, lungs, &c. than to either the arm or leg.

"We find, that injuries done to inactive parts, such as joints, do worse, and are more susceptible of irritation, than those in fleshy parts of the same situation.

"It would appear, upon the whole, that the decay of animal life is sooner brought on when the inflammation is in a part whose circulation is not so strong, and where the nervous influence on the force of the circulation is far removed."

Our author next notices that "bark is greatly recommended in gunshot wounds, and with good reason; but it is ordered indiscriminately to all patients that have received such wounds, whatever the symptoms or constitution of the patient may be. That there is no better medicine for wounds in general, not only when the inflammation is gone

off, but in the time of inflammation, *if the patient is rather low*, and indeed before it comes on, experience daily ſhews. Bark is to be looked upon as a ſtrengthener or regulator of the ſyſtem, and an antiſpaſmodic, both of which deſtroy irritation. The bark and gentle bleedings, when the pulſe begins to riſe, are the beſt treatment that I know of in inflammations that ariſe either from accidents or operations. One leſſens the volume of the blood and the increaſed animal powers at the time, which makes the circulation more free, ſo that the heart labours leſs, and ſimple circulation goes on more freely; the other gives to the blood that which makes it leſs irritating, makes the blood-veſſels do their proper office, and gives to the nerves their proper ſenſations, which takes off the fever." Hunter on the Inflammation, &c. p. 563.

To many, as well as ourſelves, this eulogium on bark may appear to extend beyond the limits of truth. We have never ſeen the propriety of denominationg bark a *ſtrengthener*, ſince it can only communicate ſtrength by putting the digeſtive organs into a better ſtate for conveying nouriſhment into the ſyſtem; and it requires a little credulity to put entire belief in ſome other qualities aſcribed to this renowned medicine by Mr. Hunter. However, we agree that bark is beneficial in many caſes of inflammation, attended with debility; and that it is particularly ſerviceable in numerous gunſhot wounds, where the object is to ſupport the conſtitution, and improve the tone of the ſtomach. Some criticiſms on the abſurd way in which bark is very commonly employed are to be found in the article GANGRENE.

In the inflammatory ſtage of gunſhot wounds, the ſeverity of the pain will often demand the exhibition of opium; but it is now pretty generally acknowledged that this medicine is not effectual in relieving pain in caſes of inflammation until the veſſels have been ſomewhat emptied by bleeding. When it is given immediately after accidents, or great operations, a large doſe muſt be given or elſe none at all; ſince a ſmall one only increaſes the fever and reſtleſſneſs of the patient. M. Chevalier adviſes us to give the firſt or ſecond opiate in an opening draught. P. 137. edit. 3.

When the patient is troubled with vomitings and ſpaſms, relief muſt be ſought for in the adminiſtration of ſuch medicines as ſaline draughts, camphor, caſtor, muſk, opium, and volatile alkali.

In gunſhot wounds, attended with true phlegmonous inflammation, M. Chevalier, after delivering his ſentiments on bleeding, recommends the exhibition of neutral ſalts and antimonials, eſpecially antimonial powder; or, he ſays, we may preſcribe a mixture of antimonials and ſaline medicines together. As long as the inflammation puts on the truly phlegmonous character ſuch means are to be continued, together with occaſional purges, and a regimen ſtrictly antiphlogiſtic.

"To the part itſelf muſt be applied poultices of bread and water, or bread and milk, or of water and linſeed meal, or of bread or linſeed meal, mixed with the aqua lithargyri acetati compoſita. Such applications will conduct off the exceſſive heat of the part; will relax the ſurface, and keep it perſpirable; will moderate the action of the veſſels, and promote the formation of matter. In hot countries, poultices made of the pulp of the water-melon, and other plants of that genus (Cucurbita), have been found exceedingly uſeful in diminiſhing the inflammation of wounds.

"But," continues M. Chevalier, "where mixed circumſtances occur, and violent action appears accompanied with diminiſhed powers, either in the part, or the conſtitution, or both, a mixed plan of treatment muſt be adopted accordingly; and where the powers are failing altogether, every effort muſt be directed to ſupport them, as the only door of hope through which the patient has any chance of eſcaping.

"The former caſe will generally be marked by the tumefaction and redneſs of the part becoming irregularly or extenſively diffuſed, and the pulſe becoming more frequent, but leſs full and ſtrong. There will be much thin diſcharge from the ſore if the orifice allows of its exit; and the pain of which the patient complains, is generally a violent aching and inexpreſſible heavineſs in the part, with leſs throbbing than takes place in phlegmon.

"Here a ſaline mixture, joined with camphor or aromatic confection, or a mixture of antimonial wine and tincture of opium, or, in other caſes, the decoction of bark with aqua ammoniæ acetatæ, or other medicines of a ſimilar kind, guarding againſt an exceſs of action on the one hand, and direct debility on the other, will be moſt beneficial.

"Applications of a ſimilar tendency muſt alſo be made to the part; fomentations, not exceeding 120° of heat, conſiſting of a decoction of white poppy heads, or a poultice made with the ſame, or, in other inſtances, the uſe of diluted ſpirit, or the embrocation (compoſed of equal parts of ſpirit of wine, aqua ammoniæ acetatæ, and water) will be moſt eligible. When theſe cannot be obtained, other remedies, keeping the ſame principle in view, muſt be employed.

"But," ſays M. Chevalier, "where the powers of nature are flagging; the pulſe becoming ſmall, frequent or irregular; the tongue dry and brown, or the bowels lax; the part inflamed veſicating, or becoming livid; whether this be more attended with the characters of eryſipelas only, or of gangrene alſo, there bark, wine, brandy, ſpices, and cordials muſt be liberally given; and opium alſo, according to the degree of pain and irritability. The part injured muſt be covered with cloths moiſtened with ſpirituous embrocations, or poultices made with yeaſt, or antiſeptic vegetables, ſuch as bark, or chamomile flowers in powder, ſhould be applied.

"If the ſtomach, in this caſe, rejects ordinary food and medicine, advantage will frequently be obtained from the warmer ſpices; ſuch, for example, as the pulvis aromaticus, a ſcruple of which may be given every three, four, or ſix hours. A pill, with three or four grains of camphor and one of opium, at the ſame, or longer intervals, will often have the happieſt effects, and will neither nauſeate nor overcharge the ſtomach." Chevalier on Gunſhot Wounds, ſect. 7. edit. 3.

Such is the kind of treatment which this gentleman recommends in the inflamed and gangrenous ſtate of a gunſhot wound; and perhaps his plan is not materially different from the ordinary courſe of practice. To us the application of ſpirituous embrocations to the part ſeems improper; but as we have ſtated our ſentiments elſewhere concerning the treatment of caſes of mortification, it only ſeems neceſſary to mention, that we have, in the ſame place, freely animadverted, both on the cuſtom of uſing topical ſtimulants, and on the irrational and pernicious way in which bark is ſometimes given, in certain inſtances, when it can do no good, and ſometimes preſcribed immoderately, ſo as to be oppreſſive and hurtful, when more reaſonable doſes might be productive of infinite benefit. See GANGRENE.

We ſhall now introduce a few remarks on the treatment of gunſhot wounds in the ſtate of ſuppuration. For the firſt few days the matter ſeldom aſſumes a healthy appearance; but as ſoon as the ſloughs ſeparate it then becomes of a proper quality, and the part is to be treated as a ſimple ſore, or abſceſs. Nothing is required but mild unirritating dreſſings or poultices, taking care to preſerve cleanlineſs, ſupport the patient's ſtrength by eligible food and medi-

cines,

cines, and attend to any particular ſymptoms which may ariſe. While there are any ſloughs undetached, and the diſcharge is profuſe, emollient poultices are always the beſt local applications; but when the wound is ſmall, covered with healthy granulations, and unattended with a great diſcharge, ſome ſoft lint, over which is to be put a pledget of ſome mild ointment, is as good a mode of treating the ſore as any which can be purſued. In this ſtate, it is evident, that the leſs the granulations are diſturbed the better.

In caſes of gunſhot wounds, the inflammation ſometimes laſts very long, and there is no appearance of ſuppuration. In other inſtances freſh inflammation comes on ſuddenly, during the ſuppurative ſtage, without any viſible cauſe, and puts a ſtop to the ſecretion of matter. Sometimes, alſo, without any manifeſt reaſon, the wound ſuppurates in an extraordinary degree. According to Richter, ſuch circumſtances very frequently depend on the lodgment of ſplinters of bone, which ſhould be extracted, if they can be felt, and taken away without creating too much irritation.

We have already noticed the riſk of hemorrhage in many gunſhot wounds, when the ſloughs become looſe. Writers mention another particularly dangerous kind of bleeding, which is apt to ariſe from certain gunſhot wounds which have long continued in a ſtate of profuſe ſuppuration. The blood does not iſſue from one individual veſſel, but from the whole ſurface of the wound as from a ſponge, and is ſo thin as to reſemble blood and water. This hemorrhage is exceſſively dangerous, becauſe it is likely to exhauſt the patient, who is already exceedingly debilitated, and its cauſes are difficult of removal. The caſe demands the exhibition of bark, alum, and diluted ſulphuric acid. At the ſame time, the decoction of bark and muriatic acid may be applied to the wound.

As ſoon as ſuppuration commences, it is common for the inflammatory ſymptoms to go off, and the ſwelling to abate. However, it is obſerved by M. Chevalier, that the ſwelling, inſtead of diſappearing entirely on a ſudden, ought only to undergo a gradual diminution, together with the other ſymptoms. For if at any period the ſwelling ſuddenly ſubſides, while the frequency of the pulſe, debility, want of appetite, and reſtleſſneſs, continue or increaſe, the death of the patient is at no great diſtance. The moſt powerful cordials and aromatics are then indicated, although unfortunately, they generally have but little effect.

The ſame gentleman alſo ſpeaks of the maggots which ſometimes infeſt gunſhot wounds in hot countries, and are only of importance inaſmuch as they produce irritation. It was remarked by Le Dran, that they are only ſeen in healthy ſores, or caſes in which a ſlough is undergoing a ſeparation, as they cannot live in the matter of an unhealthy wound. M. Chevalier adviſes a frequent removal of them, and killing them by waſhing the part with a ſtrong infuſion of wormwood in water or ſpirit, or by applying camphorated ſpirit. See Treatiſe on Gunſhot Wounds, edit. 3. p. 148—149.

It too frequently happens in the ſuppurative ſtage of bad gunſhot wounds, that the large quantity and long duration of the diſcharge, and the irritation of the diſeaſe on the conſtitution, reduce the patient to a ſtate of alarming weakneſs, attended with bad hectical ſymptoms, and the danger of diſſolution. If an immediate change of circumſtances cannot now be effected, the patient will almoſt certainly loſe his life, in ſpite of the virtues of bark and every kind of cordial and aromatic medicines. Such is often the lamentable end of thoſe caſes in which the bones or joints have been conſiderably ſhattered, as well as of other inſtances in which only a large maſs of fleſh has been torn off, or has ſloughed away in conſequence of the firſt or repeated attack of inflammation.

Whenever ſuch ſymptoms and miſchief prevail, and the wound is ſo ſituated on a limb that the diſeaſed part can be entirely taken away, and a healthy wound and good ſtump made, amputation ſhould not be delayed, as the opportunity of ſaving life is ſhort, and ought not to be loſt. No humane practitioner, however, would urge the performance of a ſevere operation, and mutilate his patient while the patient's ſtrength ſeems capable of bearing a longer attempt to preſerve the limb, or while the effects of a generous diet, bark, cordials, wine, porter, &c. had not been ſufficiently tried.

"Profuſe diſcharges," ſays M. Chevalier, "are often kept up from the wound by the continuance of extraneous ſubſtances, which may now be ſearched after with more freedom when the parts have got into a quiet ſtate. Splinters of bone will alſo have the ſame effect; and where either the former or the latter have not been, or cannot be readily removed, or ſloughs have not been completely diſcharged, abſceſſes will form, which ſhould always be freely opened as ſoon as they point externally. A free expoſure of their cavities will not only facilitate the exit of any thing which is to come away, but will generally be followed by a more ſpeedy and perfect amendment in the part. Indeed, the confinement of matter any where will always do harm, and ſhould as much as poſſible be prevented by a ſuitable poſition, and proper openings." P. 153.

Where a ſhot injures and penetrates ſome part where there is an extenſive aponeuroſis or faſcia, the inflammation excited is exceedingly apt to terminate in large collections of matter under the tendinous expanſion. In ſuch caſes the pus is greatly prevented from making its way to the ſurface of the body by the intervention of the faſcia, and, conſequently, the abſceſs ſpreads widely between the aponeuroſis and ſubjacent muſcles, and between the muſcles themſelves, ſo as to create a conſiderable augmentation of the miſchief. We have ſeen ſuch abſceſſes ariſe, when the original wound had healed up to a very ſmall fiſtulous opening, and could afford no effectual eſcape for the matter. In every caſe of this deſcription, it is the duty of the practitioner to make proper depending openings of due ſize, and not to delay doing ſo till the abſceſs has acquired a formidable magnitude.

In order to bring a patient ſafely through the tedious and weakening ſtage of a ſuppurating gunſhot wound, the ſurgeon muſt be careful to ſupport the ſtrength by nouriſhing kinds of food, adminiſter bark and tonic medicines, and allay irritation and procure ſleep by opium. Wine, porter, and ſometimes even brandy, will alſo prove of ſingular ſervice.

When the circumſtances of the caſe will permit, a change of air, and going to the ſea-ſide, will often diſpoſe ſuch abſceſſes to heal as remain ſtationary, notwithſtanding the moſt ſkilful treatment.

Fiſtulous ſinuſes are very frequent after many kinds of gunſhot wounds, and ſome of them heal up ſpontaneouſly as ſoon as the patient experiences the benefit of a change of air, and regains a certain degree of ſtrength. In other inſtances the ſinus will not heal before it is laid open with a curved biſtoury and director, and dreſſed to the bottom. When a fiſtulous opening continues a long while, it is often kept up by the preſence of ſome extraneous ſubſtance, a bit of wood, a piece of cloth, a ſplinter or ſcale of bone, an exfoliation

exfoliation, &c. Here no cure can take place till the foreign body admits of being extracted.

Of Cases in which Amputation is proper.—It is exceedingly difficult to determine by written rules what cases require the immediate performance of amputation, and what cases admit of an attempt being made to preserve a limb badly injured by gunshot violence. A habit of forming a correct judgment can only be derived from the valuable lessons of experience, and even with this opportunity of gaining knowledge, it is not every man that can imbibe the requisite information; want of abilities in the difficult and delicate parts of practice being, in effect, the same as having not the possibility of learning. We have known old grey-headed surgeons, of whom it has often been said that they had seen more surgery than any of their brethren, and of course that their opinions were highly valuable. There is, however, an essential difference between merely having things before our eyes and really seeing them. Suppose a man to have ten thousand venereal patients under his care, what avails the greatness of the number if nature has made his brains of so saturnine a composition that they are incapable of discriminating right from wrong, or of discerning the important truths which are to be gathered in the wide field of experience. One traveller may pass over a large portion of the globe, and, comparatively speaking, observe nothing that he ought to notice, while another shall make the same journey, and both see and remember every thing which is curious, useful, or in any way interesting. In surgery we must not set down a man as a consummate practitioner, because he has had opportunities of seeing a good deal, not even though he be an hospital surgeon; besides the opportunity, we must consider whether he possesses the disposition and ability to reap the fruits of experience. No one can doubt that bright talents and great attention are necessary as well as sufficient experience in the part of surgery before us, when it is recollected that Mr. Hunter himself has scarcely afforded a decided opinion respecting the cases in which amputation ought to be performed.

Many gunshot wounds are, at the very first, evidently incurable, and when so situated that the injured part can be removed, the operation ought to be done under certain restrictions. Perhaps, as Mr. Hunter remarks, it should not be done immediately after the reception of the injury, except when a considerable blood-vessel is wounded, so as to endanger life, and such vessel absolutely cannot be taken up; or when it is suspected that the inflammation, in consequence of the accident, will kill. By means of the operation, the patient is only left to encounter the inflammation in consequence of the amputation. But this celebrated surgeon represents the operation as a bad resource, especially when it is a lower extremity to be amputated, which is perhaps the only removeable part, the inflammation of which will kill.

It is a very different case, however, when the gunshot wound is so situated, that it is not likely to produce death, though in all probability it cannot be cured. Here there is not the same urgency, and the surgeon may choose whatever time may be considered as most favourable for removing the part. This time is seldom just after the accident, for few people in full health, and still fewer of those who meet with gunshot wounds, are in a state to bear the sudden performance of a capital operation well. The agitation in which they are just after being hurt, makes operating then the very worst practice. Therefore, says Mr. Hunter, it will generally be much better to wait till the inflammation, and the effects both of that and the irritation have gone off. When the practitioner overlooks these considerations, and, by deferring the operation, allows an inflammation to go on, which is likely to prove mortal; or should he, on the other hand, immediately proceed to amputation, when the first inflammation is such as is likely to go off, and ought to be allowed to go off, before the operation; in either case his conduct is wrong. For, with regard to the first instance, it is now universally admitted by all well informed surgeons, that there are not many persons who can bear the loss of a lower extremity when in full health and vigour. A violent inflammation will, in a few hours, alter the healthy disposition, and give a turn to the constitution, especially if a considerable quantity of blood has been lost, which will probably be the case, where both accident and operation immediately succeed one another. Under such circumstances the patient becomes low, simply by animal life losing its powers, and he hardly ever recovers afterwards. Hunter on Gunshot Wounds, p. 560.

A strong argument against immediately performing amputation in cases of gunshot wounds, when it is probable that the patient will get over the first inflammation, is, that it is generally impossible, just after the confusion of a battle, to pay the necessary care, and procure the requisite degree of quietude. Besides, the surgeon himself is frequently so situated, during, or just after an engagement, as to be incapable of making himself sufficiently master of the case, to perform so capital an operation with propriety.

In some cases, however, it may be urged in favour of amputation on the field of battle, that the patient can be moved with more ease without a limb, than with a shattered one. But, as Mr. Hunter acknowledges, experience is the best guide, and men who have had the best opportunities of making comparative observations, seem to agree that few do well, who have their limbs cut off on the field of battle, while a much greater proportion recover, in similar cases, who are left till the first inflammation is over, and afterwards undergo amputation.

Mr. Hunter makes mention of exceptions to the preceding remarks; first, he states that it is of less consequence what practice is adopted, when the question is concerning the upper extremity, though there will generally be little occasion to cut off an arm on the field, because the patient admits of being moved. Secondly, if the parts are very much torn, so that the limb only hangs by a slender connection, the loss of so much substance cannot make an objection, as it takes place from the accident. In many cases it may be necessary to perform the operation in order to get at blood-vessels, which may bleed profusely, and cannot be got at in any other way, without doing too much mischief.

Though gunshot wounds are not so apt to bleed as wounds made with sharp instruments, a dangerous degree of bleeding sometimes attends them, and renders it absolutely necessary to take up the bleeding vessels.

Also, when portions of the bowels or lungs are protruded, an immediate reduction of them is indispensably requisite.

Large pieces of shells driven into the flesh, should be extracted without delay.

For these purposes, the surgeon is called upon to make such incisions as will enable him to accomplish the object in view.

Gunshot Wounds of the Abdomen.—These cases may be divided into two kinds, one only penetrates the parietes of the belly without hurting the contained parts, the other does mischief also to the viscera. The event of these two kinds of wounds is very different. In the first, little danger is to be expected, if properly treated; but in the second, the success

ſucceſs will be very uncertain, for very often nothing can be done for the patient, and very often a good deal of art may be employed with advantage.

Mr. Hunter obſerves, that ſuch wounds of the abdomen as do not intereſt a viſcus, like the ſtomach, bowels, bladder, ureters, gall-bladder, blood-veſſels, &c. which contain ſome kind of matter, will generally do well. But he ſays that there will be a great difference when the ball has paſſed with immenſe velocity, as a ſlough will be produced, whereas when the ball has moved with leſs impetus, there will not be ſo much ſloughing, and the parts will in ſome degree heal by the firſt intention. Even when the ball occaſions a ſlough, the wound frequently ends well, the adheſive inflammation taking place on the peritoneum all round the wound, ſo as to exclude the general cavity of the abdomen from taking part in the inflammation. Such is often the favourable event, when the ball, beſides entering the abdomen, has wounded ſuch parts as the epiploon, meſentery, &c. and gone quite through the body; p. 543. In the article Extravasation, we have endeavoured to give ſome account of the way in which fluids are prevented, in caſes of wounds of the belly, from eſcaping out of the viſcera, and becoming widely diffuſed among the convolutions of the bowels in the cavity of the peritoneum; to that part of the Cyclopædia a reference may now be properly made. It ſeems only neceſſary to obſerve here on the ſubject, that in conſequence of the adheſions, one continued canal is generally ſoon produced, wherever a ball or inſtrument has paſſed, all extraneous ſubſtances, ſuch as bits of cloaths, and any ſloughs which may ariſe, being circumſcribed and ſurrounded by thoſe adheſions.

In gunſhot wounds of the belly, an extravaſation is apt to take place on the ſeparation of ſloughs, about eight, ten, twelve, or fourteen days after the accident; but although this new ſymptom is in general very diſagreeable, it is not to be regarded as dangerous, all the danger being uſually over before it can appear. Suppoſing the extravaſation to be inteſtinal matter or urine, the ſurgeon ſhould endeavour to prevent the continuance of an artificial anus, or urinary fiſtula. Superficial dreſſings being applied, the opening ſometimes heals up, when the contents of the wounded viſcus become ſmaller in quantity. Some remarks, connected with this part of ſurgery, will be found in the article Hernia.

The general ſymptoms of different wounds of the belly will be explained in another place, ſee Wounds, ſo that we need not dwell upon them here; and the ſame may be ſaid with regard to the proper practice to be purſued in theſe caſes.

Gunſhot Wounds of the Cheſt.—Wounds of the lungs abſtracted from other miſchief, are now well known not to be always fatal. Mr. Hunter had ſome reaſon to believe that wounds of the lungs made with balls were leſs dangerous than ſuch as were made with ſharp pointed inſtruments; for he had ſeen ſeveral patients recover after being ſhot through the lungs, while other perſons died of very ſmall wounds of theſe organs done with ſwords and bayonets. One cauſe of this fact is perhaps owing to the circumſtance of gunſhot wounds bleeding leſs than any other wounds, ſo that there was leſs danger of blood being effuſed either in the thorax or cells of the lungs. The indiſpoſition of the orifice of a gunſhot wound to heal up too ſoon, is alſo another circumſtance leſſening the hazard, as whatever matter happens to be extravaſated has thereby an opportunity of eſcaping.

It cannot be ſuppoſed that adheſions take place round the opening of a gunſhot wound in the cheſt, becauſe the lungs collapſe and become conſiderably diſtant from the pleura, whenever a free communication is eſtabliſhed between the atmoſpheric air and the cavity of the thorax. However it is known that adheſions are very common between the outer ſurface of the lungs, and inner ſurface of the pleura coſtalis, and conſequently they muſt, in numerous inſtances, exiſt before the receipt of a wound, ſo as to hinder the uſual collapſe of the lungs.

The general ſymptoms of wounds of the thorax, and alſo the treatment, will be detailed hereafter; ſee Wounds. We ſhall here only juſt remark, that when a patient has been ſhot in the cheſt, the moſt important indication is to prevent and ſubdue inflammation of the lungs and pleura. In hardly any other caſe can large and repeated bleedings be practiſed with equal advantage. The patient is likewiſe to be kept on low diet, and have the ſpermaceti mixture and opium adminiſtered to him, in caſe he ſhould be diſturbed with much coughing. Here there will not be ſo much danger of an extravaſation of blood, as in ſtabs, and even if an effuſion of that fluid were to happen, the opening would generally be ſufficient for its eſcape, and it would not be ſo frequently found neceſſary either to dilate the wound, or make a new opening into the cheſt, as when the injury has been inflicted with a ſharp pointed weapon.

When matter forms in the thorax in conſequence of gunſhot wounds, the opening will generally ſuffice for its eſcape; but ſhould the collection of pus be confined and occaſion dangerous ſymptoms, a depending opening ought to be made. The manner of practiſing that operation, and the ſymptoms requiring it, have been elſewhere explained. See Empyema.

GUNTA, in *Geography*, a town of Peru, and capital of a juriſdiction, in the dioceſe of Guamanga; 20 miles N. of Guamanga.

GUNTER, Edmund, in *Biography*, the deſcendant of a reſpectable family in Brecknockſhire, South-Wales, was born in the county of Hertford in 1581; and having been educated on the royal foundation in Weſtminſter ſchool, he was elected to Chriſt-church college, Oxford, in 1599, where he was graduated B. A. in 1603, and M. A. in 1606. About this time he entered into holy orders, and in 1615 took the degree of B. D. From his youth he was much devoted to mathematical ſtudies, and as he advanced in life his reputation in this department of ſcience increaſed. Accordingly, when a vacancy occurred in the profeſſorſhip of aſtronomy in Greſham college, London, by the reſignation of Mr. Williams, Mr. Gunter was choſen to ſucceed him, March 6th, 1619: and in this ſituation he continued till the world was deprived of his life and labours, in the year 1626, at the age of 45 years, which, conſidering the extent and variety of his diſcoveries and writings, may be reckoned an early period. He was buried in the church of St. Peter the Poor, Broad-ſtreet, without any monument or inſcription; but his inventions and publications furniſh a ſufficient record of his talents and labours. About the year 1606, he diſtinguiſhed himſelf by the new projection of his ſector, of which he wrote a Latin deſcription, circulated in MS. among his friends, but not printed till ſome time afterwards. It appears that before the year 1618 he had invented a portable quadrant, which ſerved for more eaſily finding the hour and azimuth, as well as for other uſeful purpoſes in aſtronomy. Soon after his election into Greſham college, *viz.* in the year 1620, he publiſhed his "Canon Triangulorum ſive Tabulæ ſinuum et Tangentium Artificialium, ad Radium 10.000,000, et ad Scrupula prima Quadrantis," Lond. 8vo.; to which were annexed the firſt 1000 of Briggs's logarithms, of common numbers. A ſecond edition of this work was publiſhed in Engliſh in 1623, 4to., under title of

"Canon

"Canon Triangulorum, or A Table of Artificial Sines and Tangents to a Radius of 10,000,000 parts to each Minute of the Quadrant," to which were added "Logarithms of abſolute numbers, from an unit to ten thouſand," with a rule for augmenting them to 100,000. It ought to be mentioned, to the honour of Mr. Gunter, that theſe were the firſt tables of the kind that were ever publiſhed. The utility of theſe tables is ſufficiently known to mathematicians and aſtronomers; as they facilitate the reſolution of ſpherical triangles, without the aid of ſecants or verſed ſines, and ſubſtitute the operations of addition and ſubtraction for thoſe of multiplication and diviſion. Mr. Gunter's claim to this application of logarithms to the ſolution of ſpherical triangles was ſatisfactorily eſtabliſhed by Mr. Edmund Wingate, Mr. Robert Burton, and Mr. Henry Bond, ſen. In the year 1622, Mr. Gunter found, by experiments on the variations of the magnetic needle, made at Deptford, that this variation varied, and that the declination had changed almoſt five degrees in the ſpace of 42 years; a diſcovery which was confirmed and eſtabliſhed by Mr. Gellibrand, his ſucceſſor at Greſham college. (See VARIATION.) The next invention of Mr. Gunter, which we have to record, is that of his "Rule of Proportion," by which he applies the logarithms of numbers, and alſo of ſines and tangents, to ſtraight lines drawn on a rule or ſcale; by means of which proportions in common numbers and in trigonometry may be reſolved with a pair of compaſſes, in conſequence of the now well-known principle, that the logarithms of the terms of equal ratios are equidifferent. This was called "Gunter's Proportion," and "Gunter's Line;" and the inſtrument in the form of a two foot ſcale, which is in common uſe for nautical and other purpoſes, is commonly called the "Gunter." (See the following articles.) This invention was communicated, in 1624, to the French mathematicians at Paris by Mr. Wingate, who publiſhed an account of its uſe in the French language. Several years after Mr. Gunter's death, Mr. Wingate publiſhed an Engliſh tranſlation of his French tract, with many additions and improvements, which has ſince been called Wingate's "Rule of Proportion," or more generally "Gunter's Line." To Mr. Gunter we alſo owe the improvement of the *Sector* (which ſee), and other inſtruments of ſimilar uſe; the deſcription of which he publiſhed in 1624, 4to. under the title of the "Sector, Croſs-ſtaff, and other Inſtruments." He alſo introduced the common meaſuring-chain, now conſtantly uſed in land-ſurveying, and hence called "Gunter's Chain." In the year 1624 he publiſhed, by order of king James, a ſmall tract, entitled "The Deſcription and Uſe of his Majeſty's Dials in Whitehall Garden," 4to. But it is needleſs to deſcribe theſe dials, on which the ingenious author drew the ſeveral lines, and of which he gave an account in this treatiſe, as theſe dials no longer remain; having been in a great meaſure defaced by the frolics of a certain nobleman in the reign of king Charles II.: and the ſtone upon which they were conſtructed having been removed ſince the fire at Whitehall, on the 4th of January 1697. Our ingenious author was the firſt who uſed the term "Co-ſine" for the ſine of the complement of an arc; and he alſo introduced the uſe of "Arithmetical Complements," into the logarithmical arithmetic, as we learn from Brigg's Arith. log. c. 15. It has been alſo ſaid, that he firſt ſuggeſted the idea of the "Logarithmic Curve," ſo called, becauſe the ſegments of its axis are the logarithms of the correſponding ordinates.

The works of Mr. Gunter, which were publiſhed in ſeparate tracts at different times, have been collected (his piece on the dials excepted); and various editions of them iſſued from the preſs. The fifth edition is that of Mr. W. Leybourn, 1673, 4to., containing the "Canon Triangulorum," and an account of the ſector, croſs-ſtaff, croſs-bow, portable quadrant, and other inſtruments, with ſeveral additions by Mr. Samuel Foſter, Mr. Henry Bond, and the editor, Mr. William Leybourn. Ward's Lives of the Profeſſors of Greſham College, p. 77, &c.

GUNTER's *Chain*. See CHAIN.

GUNTER's *Line*, called alſo *Line of Lines*, and *Line of Numbers*, is a graduated logarithmic line uſually placed on ſcales, rules, ſectors, &c.

This line conſiſts of the logarithms transferred upon a ruler, from the tables, by means of a ſcale of equal parts, ſo as to anſwer much the ſame purpoſes, inſtrumentally, as the logarithms themſelves do arithmetically. What the logarithms do by addition and ſubtraction, is done in this line by turning a pair of compaſſes this way and that.

This line has been contrived various ways, for the advantage of having it as long as poſſible. As, firſt, on the two feet ruler, contrived by Edmund Gunter, and called "Gunter's Scale;" whence alſo the line itſelf took its popular denomination "Gunter's Line."

After this, Wingate, in 1627, doubled the line, or laid down the logarithms on two ſeparate rulers, ſliding againſt each other, ſo that the uſe of compaſſes was ſuperſeded. In the ſame year they were applied to concentric circles by Oughtred: and about the year 1650 they were projected in a ſpiral form by Mr. Milburne of Yorkſhire. The father of the late Mr. George Adams, inſtrument-maker in Fleet Street, had a ſpiral engraved on a braſs plate, ſuppoſed to be conſtructed in the year 1748. The ſpiral has 10 turns, and its external diameter is 12 inches. It contains the numbers, ſines, and tangents, the latter being twice repeated, and may with eaſe be uſed to compute to four places, and an eſtimate figure; which is to the full as much as could be done with a common Gunter's ſcale of 60 feet in length. In 1657 they were inſcribed on the preſent common ſliding rule by Mr. Seth Partridge.

Laſtly, Mr. William Nicholſon propoſed another diſpoſition of them in concentric circles, in the Phil. Tranſ. for 1787. His inſtrument is equivalent to a ſtraight rule of the length of $28\frac{1}{2}$ inches. It conſiſts of three concentric circles, engraved and graduated on a plate of about $1\frac{1}{2}$ inch in diameter. From the centre proceed two legs, having right-lined edges in the direction of radii, which are moveable either ſingly or together. In uſing this inſtrument, place the edge of one leg at the antecedent of any proportion, and the other at the conſequent, and fix them to that angle: the two legs being thus moved together, and the antecedent legs placed at any other number, the other leg gives its conſequent in the like poſition or ſituation on the lines. The whole length of the line is divided into two equal intervals, or radii, of nine larger diviſions in each radius, which are numbered from 1 to 10, the 1 ſtanding at the beginning of the line, becauſe the logarithm of 1 is 0, and the 10 at the end of each radius: alſo, each of theſe nine ſpaces is ſubdivided into ten other parts, unequal according to the logarithms of numbers; the ſmaller diviſions being always tenths of the larger: thus, if the large diviſions be units, the ſmaller are tenth parts; if the larger be tens, the ſmaller are units or ones, and if the larger be 100, the ſmaller are tens, &c.

For other contrivance by Mr. Nicholſon, ſee his Philoſophical Journal, vol. i. p. 374, &c.

Deſcription of Gunter's Line.—The whole length of this line is divided into equal intervals, uſually called radiuſes; the firſt begins at the left-hand with the number 1; the middle

point

point between the two radiuſes, where the firſt ends and the ſecond begins, is alſo marked with number 1; and the end of the ſecond radius, which terminates the line at the right-hand end, is marked with the number 10, againſt which are inſcribed the letters *num.* Each of theſe equal radiuſes or intervals is divided into nine equal ſpaces, marked 2, 3, 4, 5, 6, 7, 8, 9; but the ſpaces in one radius are exactly of the ſame lengths with the ſpaces alike marked in the other radius; each of theſe nine unequal ſpaces are ſubdivided, firſt into ten unequal, and then each of theſe into two or more parts, ſuch as thoſe ſpaces can conveniently contain. If the left-hand 1 ſtands for the number one, the middle 1 repreſents the number 10, and the 10 at the right-hand end ſtands for the number 100, then the figures 2, 3, 4, &c. in the firſt radius ſtand for the numbers 2, 3, 4, 5, 6, 7, 8, 9; and the like figures in the ſecond radius ſtand for the numbers 20, 30, 40, 50, 60, 70, 80, and 90; and the ten firſt ſubdiviſions in the ſpaces of the ſecond radius ſtand for the reſpective units between the marked ſpaces. If the left-hand 1 be called 10, the middle 1 ſtands for 100, and the 10 at the right-hand ſtands for 1000; the ſeveral ſpaces and ſubdiviſions in the firſt interval are then to be eſtimated as thoſe were eſtimated in the ſecond radius, when the right-hand end ſtood for 100; but now, in the ſecond interval, the firſt ſubdiviſions in the ſpaces ſtand for hundreds, and the leſſer diviſions of theſe ſtand for ſuch parts of 100, as there are parts introduced; thus, where only 2 of the laſt ſubdiviſions can be introduced, each ſtands for 50; where 4 can be contained, each ſtands for 25; if 5 are put in, each ſtands for 20; and where 10 are introduced, each ſtands for 10; again, if the firſt 1 be called 100, the ſecond 1 ſtands for 1000, and the ten at the end ſtands for 10000, &c. if the firſt 1 ſtands for $\frac{1}{10}$, the ſecond 1 ſtands for 1, and the 10 at the end ſtands for 10; and in this caſe, the numbered diviſions in the ſecond radius ſtand for the units between 1 and 10; the firſt ſubdiviſions ſtand for tenth-parts of unity, and the ſecond ſubdiviſions ſtand for the parts of tenths, according to the number of theſe ſecond ſubdiviſions, &c. ſo that whatever values are put upon any diviſion or ſubdiviſion in the ſecond radius, the value of the correſponding diviſion in the firſt radius will be only a tenth-part, and *vice verſâ*: thus, if the diviſion marked 5 in the ſecond radius ſtands for 5000, or 500, or 50, or $\frac{5}{10}$, &c. then the 5 in the firſt radius will ſtand for 500, or 50, or 5, or $\frac{5}{10}$, or $\frac{5}{100}$, &c.

Conſtruction of Gunter's Line.—From a ſcale of equal parts, accurately divided, and of ſuch a length, that 20 of the primary diviſions ſhall make the whole length of the intended ſcale of numbers, take the firſt ten of theſe diviſions, and lay this diſtance down twice on the logarithmic ſcale, making two equal intervals; marking the firſt point 1, the ſecond 1, (or rather 10), and the third 10, (or rather 100). From the ſame ſcale take the diſtances expreſſed by the three firſt figures of the logarithms of the numbers 2, 3, 4, 5, 6, 7, 8, 9 reſpectively, rejecting the indices, *viz.* 301, 477, 672, 699, 778, 845, 903, 954; lay theſe diſtances on each interval of the logarithmic ſcale, between the marks 1 and 10, 10 and 100, reckoning each diſtance from the beginning of its interval, *viz.* from 1 and from 10, and mark theſe diſtances with the figures 2, 3, 4, 5, 6, 7, 8, 9, in order. The diſtances expreſſing the logarithms of the numbers between 10 and 20, 20 and 30, 30 and 40, 40 and 50, 50 and 60, 60 and 70, 70 and 80, 80 and 90, 90 and 100, rejecting the indices, are alſo to be taken from the ſcale of equal parts, and laid on the logarithmic ſcale, in each of the primary intervals between the marks 1 and 2, 2 and 3, 3 and 4, 4 and 5, 5 and 6, 6 and 7, 7 and 8, 8 and 9, 9 and 10, reſpectively, reckoning each diſtance from the beginning of its reſpective primary interval. The laſt ſubdiviſions of the ſecond primary interval are to be divided into others, as many as the ſcale will admit of, by laying down the logarithms of ſuch intermediate diviſions.

The accuracy of the diviſion of this line may be determined by taking with a pair of compaſſes the diſtance between the diviſions marked with the numbers 1 and 2, which will reach from 2 to 4, from 4 to 8, from 8 to 16, &c. and from $1\frac{1}{2}$ to 3, from 3 to 6, from 6 to 12, &c. and alſo from $1\frac{1}{4}$ to $2\frac{1}{2}$, from $2\frac{1}{2}$ to 5, from 5 to 10, &c. or the ſame diſtance applied to any one of the diviſions between 1 and 2, will reach from thence to diviſions found always by doubling the laſt number. The ſame work may be done without compaſſes, by moving the ſlider till the left-hand 1 on the line of numbers ſtands againſt the diviſion expreſſing any number counted on the fixed line of numbers, then will the diviſions 2, 4, 8, 16, 32, &c. on the ſlider ſtand againſt the reſpective diviſions on the fixed line, which will repreſent twice 4 times, 8 times, 16 times, &c. the diviſion againſt which the 1 on the ſlider was ſet. Theſe diviſions on the fixed line which correſpond to the diviſions 2, 4, 8, 16, &c. on the ſlider will be cut by the edge of the braſs index by moving it along to the diviſions on the ſlider.

To find a diviſion or point in the line of numbers anſwering to any given number.—Let the number be 654: ſeek in the ſecond radius between the figures 6 and 7 for the fifth of the firſt ſubdiviſions; between this fifth and ſixth are 4 ſecond ſubdiviſions, each of which anſwers to $2\frac{1}{2}$ units; then will a point taken a little nearer to the ſecond than the firſt of theſe ſmaller ſubdiviſions anſwer to the number 654 very nearly; the correſpoding point in the firſt radius anſwers to the number 654, and if this point in the firſt radius anſwered to 654, the like point in the ſecond would anſwer to 6540. Let the number be 168: in the ſecond radius between 1 and 2, ſeek the ſixth of the larger ſubdiviſions, and the point will fall between this ſixth and the ſeventh of the ſubdiviſions, and the true point will be on the eighth of the ſmaller ones, which will repreſent the number 168; the like diviſion in the firſt radius repreſents 168, but if this ſtood for 168, then the like diviſion in the ſecond radius ſtands for 1680.

To find a fraction, conſider that the line properly only expreſſes decimal fractions, as thus, $\frac{1}{10}$, or $\frac{1}{100}$, or $\frac{1}{1000}$, and nearer the rule cannot well come than one inch, one-tenth, one-hundredth, or one-thouſandth part of an inch: ſo that for other fractions, as quarters, half quarters, &c. you muſt either eſtimate them as near as you can reaſonably, or elſe reduce them into decimals.

Uſe of Gunter's Line. 1. *Two numbers being given, to find a third geometrical proportional to them; and to three a fourth number, to a fourth a fifth, &c.*—Extend the compaſſes on the line from one number to another; then if that extent be applied upwards and downwards, as you would either increaſe or diminiſh the number from either of the numbers, the moveable point will fall on the third proportionable number required. Again, the ſame extent, applied the ſame way from the third, will give a fourth; and from the fourth a fifth, &c.

For example: let the two numbers 2 and 4 be propoſed to find a third proportional, &c. to them; extend the compaſſes on the firſt part of the line of numbers, from 2 to 4; which done, and the ſame extent being applied upwards from 4, the moveable point will fall on 8, the third proportional required; and from 8 it will reach to 16, the fourth proportional; and from 16 to 32, the fifth, &c. Contrariwiſe, if you would diminiſh, as from 4 to 2, the moveable point will fall on 1, and from 1 to $\frac{5}{10}$, or .5; and from .5 to .25, &c.

But generally in this, and in moſt other works, make uſe of the ſmall diviſions in the middle of the line; that you may the better eſtimate the fractions of the numbers you make uſe of; for how much you miſs in ſetting the compaſſes to the firſt and ſecond term, ſo much the more you will err in the fourth; therefore the middle part will be moſt uſeful. For example, as 8 to 11, ſo is 12 to 16.5, if you imagine one integer to be divided into ten parts, as they are on the line on a two-feet rule. See SLIDING-*rule*.

2. *One number being given to be multiplied by another, to find the product* —Extend the compaſſes from 1 to the multiplicator; and the ſame extent, applied the ſame way from the multiplicand, will make the moveable point fall on the product: thus, if 6 be given to be multiplied by 5, extending the compaſſes from 1 to 5, the ſame extent will reach from 6 to 30, the product ſought.

3. *One number being given to be divided by another, to find the quotient.*—Extend the compaſſes from the diviſor, *e. g.* 25, to 1, and the ſame extent will reach from the dividend, *e. g.* 750, to the quotient 30; or extend the compaſſes from the diviſor to the dividend, the ſame extent will reach the ſame way from 1 to the quotient.

4. *To reduce a vulgar fraction into a decimal.*—In this caſe, the denominator of the given fraction is to the numerator as 1 is to the decimal required: let the fraction be $\frac{7}{8}$, extend the compaſſes from 8 to 7, and this extent laid the ſame way from 1 will reach to .875, the required decimal.

5. *Three numbers being given, to find a fourth in direct proportion* —Extend the compaſſes from the firſt number, ſuppoſe 7, to the ſecond, *e. g.* 22: that done, the ſame extent, applied the ſame way from the third, 28, will reach to the fourth proportional ſought, *viz.* 44, which is the circumference of a circle, whoſe diameter is 28, by Archimedes's proportion.

6. *Three numbers being given, to find a fourth in inverſe proportion.*—Extend the compaſſes from the firſt of the given numbers, ſuppoſe 60, to the ſecond of the ſame denomination, *viz.* 30; if that diſtance be applied from the third number backwards, 5, it will reach to the fourth number ſought, 2.5.

7. *Three numbers being given, to find a fourth in duplicate proportion* —If the denominations of the firſt and ſecond terms be lines, extend the compaſſes from the firſt term to the ſecond, of the ſame denomination: this done, that extent being applied twice the ſame way from the third term, the moveable point will fall on the fourth term required. *E. gr.* the area of a circle, whoſe diameter is 1, being 0.78539, what will the content of a circle be, whoſe diameter is 28? Apply the extent from 1 to 28, the ſame way from .785 twice, the moveable point will fall on 616, the fourth proportional or area ſought.

8. *Having three numbers given, to find a fourth in triplicate proportion* —In this caſe the firſt and ſecond terms muſt be always in the ſame denomination: *e. g.* if an iron bullet of 4 inches diameter weighs 9 pounds, what is the weight of another of the ſame metal, whoſe diameter is 6 inches: the extent from 4 to 6, laid on three times from 9, will reach to 30, 3 pounds.

9. *To find a mean proportional between two given numbers.*—Biſect the diſtance between the given numbers, the point of biſection will fall on the mean proportional ſought. Thus the quotient of the two extremes divided by one another, extremes being 8 and 32, the middle point between them will be found 16.

10. *To find two mean proportionals between two given lines.*—Triſect the ſpace between the two given extremes; the two points of triſection will give the two means required; thus, if 8 and 27 be the two given extremes, the two means will be found 12 and 18.

11. *To find the ſquare root of any number under* 1000000.—The ſquare root of a number is always a mean proportional between 1, and the number whoſe root is required; yet, with this general caution, that if the figures of the number be even, that is 2, 4, 6, 8, 10, &c. then you muſt look for the unit at the beginning of the line, and the number in the ſecond part or radius, and the root in the firſt part; or rather, reckon 10 at the end to be unity; and then both root and ſquare will fall backwards towards the middle in the ſecond length or part of the line. If they be odd, the middle 1 will be moſt convenient to be counted unity, and both root and ſquare will be found from thence forward towards 10. On this principle the ſquare root of 9 will be found to be 3; the ſquare root of 64, to be 8, &c.

12. *To find the cube root of any number under* 1000000000.—The cube root is always the firſt of two mean proportionals between 1 and the given number, and therefore to be found by triſecting the ſpace between them. Thus the cube root of 1728 will be found 12; the root of 17280, nearly 26; the root of 172800 almoſt 56.

Though the point on the line repreſenting all the ſquare numbers is in one place, yet, by altering the unit, it produces various points and numbers for their reſpective roots. The rule to find this is, to put dots, or to ſuppoſe them put, over the firſt figure to the left hand, the fourth figure, the ſeventh, and the tenth: if then the laſt dot on the left-hand falls on the laſt figure, as it does in 1728, the unit muſt be placed at 1 in the middle of the line, and the root, the ſquare, and the cube, will all fall forward to the end of the line.

If it fall on the laſt but 1, as in 17280, the unit muſt be placed at 1 in the beginning of the line, and the cube in the ſecond length; or the unit may be placed at 10 at the end of the line, and then the root, the ſquare, and cube, will all fall backwards, and be found in the ſecond part between the middle and end of the line. Thus will the cube root of 8 be found 2; and that of 27, 3; that of 64, 4; that of 125, 5; that of 216, 6, &c.

We may obſerve in general, with regard to theſe two laſt problems, that the line of numbers is only a line of logarithms, and any logarithm divided by 2, quotes the logarithm of the ſquare root of its natural number; if divided by 3, it gives the logarithm of the cube root, and if by 6, it gives the logarithm of the ſixth power, &c. Hence the roots of all powers may eaſily be found on the line of numbers, by dividing the diſtance or extent on the ſcale, between unity and the number given to be extracted, into as many equal parts as are directed by the index of that power, *i. e.* the ſquare into 2 equal parts; the cube into 3; the biquadrate into 4, &c. which half, third, fourth, &c. part, taken in the compaſſes, and laid off from unity (obſerving well the notation, or value of the figures) will give the reſpective root required.

For the particular uſe of Gunter's line in the meaſuring of timber, gauging of veſſels, &c. ſee SLIDING RULE.

For other uſes in geometry, trigonometry, &c. ſee SECTOR, and GUNTER's *ſcale*.

GUNTER's *Quadrant*, is a quadrant made of wood, braſs, or ſome other ſubſtance; being a kind of ſtereographic projection on the plane of the equinoctial, the eye being ſuppoſed in one of the poles: ſo that the tropic, ecliptic, and horizon, form the arches of circles, but the hour-circles other curves, drawn by means of ſeveral altitudes of the ſun, for ſome particular latitude every day in the year.

The

The uſe of this inſtrument is to find the hour of the day, the ſun's azimuth, &c. and other common problems of the globe; as alſo to take the altitude of an object in degrees.

See its deſcription and uſe more at large under the article *Gunter's* QUADRANT.

GUNTER'S *Scale*, alſo called by navigators abſolutely, *The Gunter*, is a large plain ſcale, with various lines upon it, of great uſe in working queſtions in navigation, &c. See SCALE and SAILING.

This inſtrument derives its name from its inventor, Mr. Edmund Gunter, who was profeſſor of aſtronomy in Greſham college, and firſt publiſhed the ſcales of logarithms, numbers, ſines, and tangents, in his deſcription of the croſſ-ſtaff, in 1624. The errors which had crept into Gunter's ſcale, by length of time and negligence in the fabrication of it, have been corrected by the late Mr. John Robertſon, late librarian to the Royal Society, and the inſtrument has been re-conſtructed, under his inſpection and with his improvements, by Meſſrs. Nairne and Blunt, mathematical inſtrument makers in London. See a deſcription of this inſtrument in its improved ſtate by W. Mountain, F. R. S. publiſhed in 1778.

On one ſide of the ſcale, repreſented *Plate* I. *Trigonom. fig.* 1. are the lines of numbers, marked *numbers*; the line of artificial ſines, marked *ſines*; the line of artificial tangents, marked *tangents*; the line of artificial verſed ſines, marked *V. S.* the artificial ſines of the rhumbs, marked *S. R.* the artificial tangents of the rhumbs, marked *T. R.* meridian line in Mercator's chart, marked *Merid.* and equal parts marked *E. P.*

To which, on the ſhorter ſcales of a foot long, are uſually added lines of latitudes, hours, and inclinations of meridians. On the backſide of the ſcale are the lines uſually found on a plain ſcale.

The lines of artificial ſines, tangents, and numbers, are ſo fitted on this ſcale, that by means of a pair of compaſſes, any problem, whether in right-lined or ſpherical trigonometry, may be ſolved very expeditiouſly, and with tolerable exactneſs; whence the inſtrument becomes extremely uſeful in all parts of mathematics where trigonometry is concerned, as navigation, dialling, aſtronomy, &c.

The ſame lines are alſo occaſionally laid down on rulers to ſlide by each other; hence called *ſliding Gunters*; ſo as to be uſed without compaſſes: but he that underſtands how to uſe them with, may, by what we have ſaid of Everard's and Coggeſhall's ſliding rules, uſe them without. See SLIDING-*rule*.

The Gunter's ſcale, as it has been lately improved, is made 30 inches long, two inches broad, and about half an inch thick. One face contains the natural ſcales; half the length of this face is filled with ſcales of equal parts; which are denominated by the diviſions of an inch, *viz.* ſcales of 10, 12½, 15, 20, 25, 30, 35, 40, 45, 50, and the left-hand primary diviſion of each ſcale is divided into 10 equal parts, and alſo into 12 equal parts: on the other half of this face are put the ſeveral lines which conſtitute the plain *ſcale*, ſuch as the ſcales of rhumbs, chords, ſines, ſecants, tangents, and half-tangents, fitted to a radius of two inches; alſo the dialling ſcales, *viz.* inclination of meridians, latitudes, chords, and hours, to a radius of two inches; and a ſcale of chords and miles of longitude to a radius of three inches, and other ſcales of chords and rhumbs to a radius of one inch. The breadth of the other face, which contains the logarithmic ſcales, is divided into 12 parts, or ſcales running nearly the whole length: nine of theſe ſcales may be called fixed, and the other three moveable, being on a ſliding piece of about 30½ inches long, ½ an inch broad, and of the thickneſs of the ſcale. The other of theſe ſcales, or lines, is,

Fixed	1.	A line of fine rhumbs, marked	S. R.
	2.	A line of tangent rhumbs, marked	T. R.
	3.	A line of verſed ſines, marked	V. S.
	4.	A line of ſines, marked	Sin.
Sliding	5.	A line of ſines, marked	Sin.
	6.	A line of numbers, marked	Num.
	7.	A line of tangents, marked	Tan.
Fixed	8.	A line of tangents, marked	Tan.
	9.	A line of numbers, marked	Num.
	10.	A line of meridian degrees to 50, marked	Mer.
	11.	A line of meridian degrees from 50 to about 74, marked	Mer.
	12.	A line of degrees of longitude, marked	Lon.

Along this face an index or thin piece of braſs, about an inch broad, is contrived to ſlide, which going acroſs the edge of the ſcales at right angles to it, will ſhew on the ſeveral lines the diviſions which are oppoſite to one another, although the lines are not contiguous. The apparatus at the right hand conſiſts of a braſs box and two ſcrews; the ſlider paſſes freely through the box, when the perpendicular ſcrew is caſed, and may be readily ſet by hand to the terms given; but for greater accuracy, and in order to keep the ſlider in its true poſition, move the perpendicular ſcrew, which by a ſub-ſpring will fix the ſlider in the box, and then by the motion of the horizontal ſcrew, the greateſt degree of accuracy poſſible may be obtained. Compaſſes may be uſed with this ſcale, as well as with the common Gunter, by firſt bringing the radius on the ſlider exactly in a line with the others on the right hand and fixing it there. In a convenient part of this inſtrument are marked 10 ſea-feet, each of which contains 13.8258 Engliſh inches, and each foot is divided into 12 equal parts, called ſea-inches. The method of forming and graduating the ſeveral lines on Gunter's ſcale is as follows: the conſtruction of the line of numbers has been already explained: for the line of logarithmic ſines, it is to be obſerved, that this line terminates at 90 degrees, juſt againſt the 10 at the end of the line of numbers; and from this termination the degrees are laid backwards, or from thence towards the left: in order to obtain diviſions anſwering to theſe, ſeek in a table of logarithmic ſines the numbers expreſſing the arithmetical complements of the ſeveral degrees, without the index: take theſe numbers from the ſcales of equal parts by which the lines of numbers was formed, and apply them to the ſcale of lines from 90°. Then the arithmetical complements of the logarithmic ſines (or the co-ſecants) abating the index, of 10°, 20°, 30°, 40°, &c. are the numbers 76033, 46595, 30103, 19193, &c. and the equal parts anſwering to theſe numbers will give the diviſions for 10°, 20°, 30°, 40°, &c. and proceed in the ſame manner for the intermediate degrees. The arithmetical complement of the ſine of 50° 44′ 21″ will be equal to 10 of the primary diviſions of the ſcale of equal parts, or to one interval in the logarithmic ſcale: ſo that a decreaſe of the index by unity anſwers to one interval; then a decreaſe of the index by 2 anſwers to two intervals, or the whole length of the logarithmic ſcale, which happens at the ſine of 0° 34′ 23″; and the diviſions anſwering to the ſine of a little above 3′, *viz.* 3′ 27″, will be equal to three intervals, and the ſine of 21″ will be four intervals; and therefore all the ſines between 90° and 0° 34′ are thoſe only which can be put on this ſcale, the leſſer ſines extending beyond this length. It has been uſual to

inſert the diviſions to every 5′, as far as 10°; from 10° to 30°, the ſmall diviſions are made 15′ each; from 30° to 50°, every half degree is marked; from 50° to 70° only the whole degrees. On the improved ſcale the ſpace between 90° and 80° is too ſmall to admit of more than five diviſions; that neareſt to the 90° being the mark for 85°; between 80° and 60°, the diviſions are ſingle degrees; from 60° to 50° every degree and half degree are introduced: from 50 to 30′ are degrees and third-parts, or every 20′; from 30 to 20° are degrees and quarters, or every 15′; and from 20° downwards are put in the degrees and ſixth parts of degrees. This line of ſines is put the uppermoſt of the three on the ſlider, and alſo the loweſt on the upper part of the fixed ſcales, whereby the two ſcales of ſines are contiguous.

For the line of tangents, it is evident, ſince the tangent of 45° is equal to the radius, or ſine of 90°, that 45° on this ſcale will terminate directly oppoſite to 90° on the ſines; and the ſeveral diviſions of this ſcale of logarithmic tangents are conſtructed in the ſame manner as thoſe of the ſines, by applying their arithmetical complements backwards from 45°, or towards the left hand. The degrees above 45 are to be counted backwards on the ſcale; thus, the diviſion at 40, repreſents both 40° and 50°, &c. In the new ſcale this line deſcends as low as o 34′ on the ſines; the ſpace between 10° and 45°, and back again from 45° to 80° are large enough to admit of four ſpaces in each; and therefore the ſubdiviſions between 10° and 80° extend to every 15 minutes; but the degrees under 10 and above 80 are each ſubdivided into ſix parts, of 10 minutes each. This line of tangents is like that of ſines, laid down twice on the new Gunter, once on the ſlider and once on the loweſt fixed part. The conſtruction of theſe lines of ſines and tangents, above explained, depends on the following theorems in trigonometry: 1. The coſine is to the radius as the radius is to the ſecant. 2. The ſine is to the radius as the radius is to the co-ſecant. 3. The tangent is to the radius as the radius is to the co-tangent. From theſe theorems it appears, that, if the radius of the tables be ſuppoſed equal to one, in either of the above caſes, one of the quantities will be equal to the quotient of unit divided by the other; but diviſion is performed by ſubtraction with logarithms, and the ſubtraction of a logarithm is the ſame as the addition of its arithmetical complement: conſequently, the logarithmic coſine and ſecant of the ſame degrees are the arithmetical complements of one another: and, as the arithmetical complement of any number is what that number wants of unity in the next ſuperior place, every natural ſine and its arithmetical complement are together equal to radius. Therefore, ſince the ſines begin at one end of the radius and terminate in 90° at the other end, in a ſcale of ſines, the arithmetical complement of any ſine or its co-ſecant, laid backwards from 90°, gives the diviſion for that ſine: and the caſe will be the ſame in a ſcale of logarithmic ſines. And as the logarithmic tangents and co-tangents are the arithmetical complements of one another, the diviſions to the degrees both under and above 45, in a ſcale of logarithmic tangents, are equally diſtant from the diviſion of 45°; conſequently, the diviſions ſerving for the degrees under 45 will ſerve, by reckoning backwards, for thoſe above 45.

For the verſed ſines: from the ſcale of equal parts take the arithmetical complements of the logarithmic coſines, or the ſecants of the complements, of 5, 10, 15, 20, 25, 30, &c. degrees, rejecting the indices; and the double of theſe diſtances will give the diviſions, on the propoſed ſcale of verſed ſines, expreſſing 10, 20, 30, 40, 50, 60, &c. degrees, continued and divided according to the length of the ſcale: otherwiſe having a table of logarithmic verſed ſines to 180°, ſubtract each logarithmic verſed ſine from that of 180 degrees, and lay the remainders ſucceſſively taken from the ſcale of equal parts on the ruler backward from the common termination. This line of verſed ſines begins at 0°; and runs thence towards the left hand to about 168°; one extremity of this line has the ſame termination with the lines of numbers, ſines, and tangents, where the mark for 180° ſhould be placed, but as the ſcale begins at this place, and the diviſions may be ſuppoſed to go backwards, therefore 0 is put for the beginning, and the numbers thence proceeding through 10, 20, &c. towards the left, are only the ſupplements of the verſed ſines themſelves.

On the new ſcale, the diviſions under 10° fall too cloſe to one another to be diſtinguiſhed; from 10° to 60° every ſingle degree is introduced; from 60° to 100° every degree and half degree; from 100° to 130° every degree and third of a degree; from 130° to 150° every degree and quarter of a degree; and above 150° every degree and ſixth part of a degree.

The conſtruction of the lines of ſine rhumbs and tangent rhumbs is eaſily underſtood; as theſe are formed by taking the ſines and tangents of the degrees and minutes anſwering to the rhumbs and parts of rhumbs from the lines of ſines and tangents reſpectively, and laying them down on their proper ſcales.

The ſcale of longitude is alſo a line of equal parts repreſenting the lengths of degrees of longitude, or of the degrees taken on the equator, in which the reckoning of a ſhip's longitude at ſea is kept; each degree, in the new ſcale, being about half an inch, and ſubdivided into 10 parts of ſix minutes each.

The ſcale of meridional degrees is formed from the preceding, and ſhews the length of the degrees of latitude, relative to the correſpondent degrees of longitude; the degrees being gradually increaſed in the ſame proportion as the degrees of longitude on the globe diminiſh from the equator towards either pole; and each of them is ſubdivided into ten parts of ſix minutes each.

This ſcale comprehends, in the improved Gunter, two lengths of the ruler; the firſt length extends from the beginning at 0° on the right, and proceeds thence towards the left as far as 50°; and begins again on the right hand at 50°, and goes on to the left as far as 75°, which is as far as moſt navigators extend, except thoſe of the Greenland fiſheries.

GUNTER'S *Scale, uſe of.* 1. *The baſe of a right-lined, right-angled triangle being given,* 30 *miles, and the oppoſite angle thereto* 26 *degrees, to find the length of the hypothenuſe.*—The trigonometrical canon or proportion is thus: as the ſine of the angle, 26 degrees, is to the baſe, 30 miles, ſo is the radius to the length of the hypothenuſe. Set one foot of the compaſſes, therefore, on the 26th degree of the line of the ſines, and extend the other to 30 on the line of numbers; and the compaſſes remaining thus opened, ſet one foot on 90 degrees, or the end of the line of ſines, and extend the other on the line of numbers: this will give 68½ miles for the hypothenuſe ſought.

2. *The baſe of a right-angled triangle being given,* 25 *miles, and the perpendicular,* 15, *to find the angle oppoſite to the perpendicular.*—As the baſe, 25 miles, is to the perpendicular, 15 miles, ſo is the radius to the tangent of the angle ſought. Extend the compaſſes, then, on the line of numbers, from 15, the perpendicular given, to 25, the baſe given; and the ſame extent will reach the contrary way, on the line of tangents, from 45 degrees to 31 degrees, the angle ſought.

3. *The baſe of a right-angled triangle being given, ſuppoſe* 20 *miles,*

miles, and the angle oppoſite to the perpendicular 50 *degrees, to find the perpendicular.*—As radius is to the tangent of the given angle, 50 degrees, ſo is the baſe, 20 miles, to the perpendicular ſought. Extend the compaſſes then on the line of tangents, from the tangent of 45 degrees to the tangent of 50 degrees; and the ſame extent will reach on the line of numbers the contrary way, from the given baſe, 20 miles, to the required perpendicular, $23\frac{3}{4}$ miles.

Note, the extent on the line of numbers is here taken from 20 to $23\frac{3}{4}$ forwards; that the tangent of 50 degrees may be as far beyond the tangent of 45 degrees, as its complement, 40 degrees, wants of 45 degrees.

4. *The baſe of a right-angled triangle being given, ſuppoſe* 35 *miles, and the perpendicular,* 48 *miles, to find the angle oppoſite to the perpendicular.*—As the baſe, 35 miles, is to the perpendicular, 48 miles, ſo is radius to the tangent of the angle ſought. Extend the compaſſes from 35 on the line of numbers to 48, the ſame extent will reach the contrary way on the line of tangents, from the tangent of 45 deg. to the tangent of 36 deg. 5 min. or 53 deg. 55 min. To know which of thoſe angles the angle ſought is equal to, conſider that the perpendicular of the triangle being greater than the baſe, and both the angles oppoſite to the perpendicular and the baſe making 90 deg. the angle oppoſite the perpendicular will be greater than the angle oppoſite to the baſe; and conſequently the angle, 43 deg. 55 min. will be the angle ſought.

5. *The hypothenuſe of a right-angled ſpherical triangle being given, ſuppoſe* 60 *degrees, and one of the ſides* 20 *degrees, to find the angle oppoſite to that ſide.*—As the ſine of the hypothenuſe, 60 deg., is to radius, ſo is the ſine of the given ſide, 20 deg., to the ſine of the angle ſought. Extend the compaſſes on the line of ſines from 60 deg. to the radius, or 90 deg. and the ſame extent will reach on the line of ſines the ſame way, from 20 deg. the given ſide, to 23 deg. 10 min. the quantity of the angle ſought.

6. *The courſe and diſtance of a ſhip being given, to find the difference of latitude and departure.*—Suppoſe a ſhip ſails from the latitude of 50 deg. 10 min. north, S.S.W. 48.5 miles; as radius is to the diſtance ſailed 48.5 miles, ſo is the ſine of the courſe, which is two points, or the ſecond rhumb from the meridian, to the departure. Extend the compaſſes from 8 or 90 deg. on the artificial ſine rhumb-line to 48.5 on the line of numbers, the ſame extent will reach the ſame way from the ſecond rhumb, on the line of artificial ſines of the rhumbs to the departure weſting 18.6 miles.

Again, as radius is to the diſtance ſailed 48.5 miles, ſo is the coſine of the courſe, 67 deg. 30 min. to the difference of latitude. Extend your compaſſes from the radius, on the line of ſines, to 48.5 miles on the line of numbers; the ſame extent will reach the ſame way, from 67 deg. 30 min. on the line of ſines, to 44.8 on the line of numbers; which converted into degrees by allowing 60 miles to a degree, and ſubtracted from the given north latitude, 50 deg. 10 min. leaves the remainder 49 deg. 25 min. the preſent latitude.

This problem may be eaſily ſolved with the ſlider, by ſetting 48.5 on the ſlider againſt 90 on the line of ſines, or 8 on the line of fine-rhumbs; then againſt two points, or 22 deg. 30 min. on the line of ſines, is 18.6, the departure; and againſt two points on the line of fine-rhumbs, or 22 deg. 30 min. on the line of ſines, is 44.8 on the ſlider, for the difference of latitude.

7. *The difference of latitude and departure from the meridian being given, to find the courſe and diſtance.*—A ſhip from the latitude 59 deg. north, ſails north-eaſtward till ſhe has altered her latitude 1 deg 10 min. or 70 miles, and is departed from the meridian 57.5 miles, to find the courſe and diſtance. As the difference of latitude, 70 miles, is to radius, ſo is the departure, 57.5 miles, to the tangent of the courſe, 39 deg. 20 min. or three points and a half from the meridian. Extend the compaſſes from the fourth rhumb, on the line of artificial tangents of the rhumbs, to 70 miles on the line of numbers, the ſame extent will reach from 57.5 on the line of numbers, to the third rhumb and a half on the line of artificial tangents of the rhumbs.

Again, as the ſine of the courſe, 39 deg. 20 min. is to the departure, 57.5 miles, ſo is the radius to the diſtance, 90.6 miles. Extend the compaſſes from the third rhumb and a half, on the artificial lines of rhumbs, to 57.5 miles on the line of numbers; that extent will reach to the ſine of the eighth rhumb, on the lines of the rhumbs, to 90.6 miles on the line of numbers.

8. *Three ſides of an oblique ſpherical triangle being given, to find the angle oppoſite to the greateſt.*—Suppoſe the ſide A B, *Tab. Trig. fig.* 2. be 40 deg. the ſide B C 60 deg. and the ſide A C 96 deg. to find the angle A B C. Add the three ſides together, and from half the ſum ſubtract the greater ſide A C, and note the remainder: thus *e. gr.* the ſum will be 196 deg. half of which is 98 deg. from which ſubtracting 96 deg. the remainder is 2 deg.

Then extend the compaſſes from the ſine of 90 deg. to that of the ſide A B 40 deg. and applying this extent to the ſine of the other ſide B C 60 degrees, you will find it reach to a fourth ſine 34 degrees.

Again, from this fourth ſine extend the compaſſes to the ſine of the half ſum, *i. e.* the ſine of 72 deg. the ſupplement of 98 deg. to 180; this ſecond extent will reach from the ſine of the difference 2 deg. to the ſine of 3 deg 24 min. againſt which, on the verſed ſines, ſtand 151 deg. 50 min. the quantity of the angle ſought.

GUNTERSBERG, in *Geography*, a town of Germany, in the duchy of Anhalt Bernburg; 28 miles S.W. of Bernburg. N. lat. 51° 39′. E. long. 11° 11′.

GUNTOOR, called alſo *Mortizanagur* and *Condavir*, a circar of Hindooſtan, ceded to the Eaſt India company, which occupies the ſpace between Condipally, the ſouthernmoſt of our four circars, and the northern part of the Carnatic; extending along the ſea-coaſt of the bay of Bengal, more than 30 miles. The poſſeſſion of this diſtrict to the Engliſh is extremely eligible, as well for the purpoſe of ſhutting out the French nation from the Deccan, as to keep open a communication with the northern circars, and to preſerve the continuity of our poſſeſſions, and thoſe of our allies. Although the maritime parts of this circar are flat and open, yet the interior part of it contains ſome very ſtrong fortreſſes and poſts. The principal poſt in this circar is *Gondavir*: which ſee.

GUNTRAS, a town of S. America, in the province of Chocos, on a river of the ſame name; 130 miles S. of Popayan.

GUNTZ, or Kesseg, a town of Hungary, on a river of the ſame name, with a caſtle, ſurrounded by a rampart and ditch, in a country abounding with corn and wine; 40 miles S. of Vienna.

GUNWALE, or Gunnel *of a Ship*, is that piece of timber which reaches on either ſide of the ſhip, from the half deck to the fore-caſtle, being the uppermoſt bend, which finiſhes the upper works of the hull in that part, and wherein they put the ſtanchions which ſupport the waſte-trees. This is called the gunwale, whether there be guns in the ſhip or not. The lower part of any port, where any ordnance are, is alſo termed the gunwale.

GUNZ, Juste-Godefroid, in *Biography*, was born at Konigſtein, in the electorate of Saxony, on the 1ſt of March,

G U R

March, 1714, his father being a Lutheran minister at that place. After attending his courses of humanity and philosophy at Gorlitz, he determined on following the profession of medicine, and went to Leipsic with a view of studying that science in 1733, and graduated there in 1738. The elector of Saxony, who was an active patron of merit, appointed him immediately to the professorship of anatomy and surgery at Leipsic; in consequence of this appointment, of the importance of which he was fully aware, Gunz requested permission to travel, in order to accomplish himself more fully in the requisite acquirements, and he visited the principal schools of Germany. He taught at Leipsic with considerable reputation; and, in 1750, was sent for to Dresden to attend the elector, who had become an invalid. His reputation at court soon equalled that which he had attained as a teacher, and was rapidly augmenting, when he was cut off by death in 1754, in the 41st year of his age. He left a considerable number of works, chiefly upon anatomical and surgical subjects. Eloy. Dict. Hist.

GUNZBURG, in *Geography*, a town of Germany, in the marggravate of Burgau, at the conflux of the rivers Gunz and Danube, where the regency of the marggravate resides; 15 miles E. of Ulm. N. lat. 48° 26'. E. long. 10° 15'.

GUNZENHAUSEN, a town of Germany, in the marggravate of Anspach, on the Altmuhl; containing two churches and an hospital; 10 miles S.S.E. of Anspach. N. lat. 49° 7'. E. long. 10° 43'.

GUPHONISSA, two small islands in the Grecian Archipelago, called *Great* and *Little*; three miles S. E. of Naxia.

GUPINDAPORUM, a town of Bengal; 70 miles S. of Dacca.

GUR, in *Mining*, is a supposed substance, which gave rise to or was the mother of metals: a substance of a white mucous-like appearance, in contact with lead ore, in the shale, in Shaw-engine mine, near Eyam, in Derbyshire, is mentioned by Mr. Whitehurst, "Inquiry," 2d edit. p. 183, which it was conjectured might have generated the ore: whether the gur of the older miners was of this kind we are unable to learn. The colliers speak of seed of coal, or coal-seed, much in the same way as the lead miners do of their gur, and perhaps with as much reason.

GUR, or *Ghur*, in *Mineralogy*, a word used to express a fluid matter looking like milk, but reduced sometimes, by evaporation, to the consistence of honey, and appearing in form of a white sediment. It is common in the mines of Sweden, and in some other places; it is sometimes calcareous or chalky, and sometimes metallic, and by dropping forms stalactitical concretions. Bromell. de Lapid.

GUR-*Lough*, in *Geography*, a lake of Ireland, in the county of Limerick.

GURÆI, in *Ancient Geography*, a people through whose territory Alexander passed in his march to the Indus; probably part of the present Cabul.

GURAGAMA, in *Geography*, a town of Bengal; 24 miles N.W. of Purneah.

GURAUNDI, in *Ornithology*, a name given to the TANAGRA *Violacea*, otherwise called *Teitei*.

GURBA, in *Geography*, a town of Africa, on the E. coast of the kingdom of Tunis, anciently called "Curobis," formerly a considerable place, though the only remaining traces of its ancient grandeur are the ruins of an aqueduct and cisterns, part of it has been swallowed up by the sea; 35 miles E.S.E. of Tunis. N. lat. 36° 34'. E. long. 11° 10'.

GURBE, a town of the island of Ceylon; 18 miles E.S.E. of Columbo.

GURBOS, or HAMMAM-GURBOS, a town of Africa, on the E. side of the bay of Tunis, anciently called "Carpis," where are seen the ruins of an ancient hot-bath and other buildings; 23 miles E. of Tunis.

GURCK, a town of the duchy of Carinthia, on a river of the same name, which discharges itself into the Drave; within the territories of the archbishopric of Salzburg, the see of a bishop. The principal article of its trade is iron; 12 miles N. of Clagenfurt. N. lat. 46° 50'. E. long. 13° 58'.

GURCKFELD, a town of Lower Carniola, on the Save; 12 miles S.S.E. of Cilly. N. lat. 49° 59'. E. long. 15° 20'.

GURDAIZ, or KERDIZ, a town of Candahar; 28 miles E. of Ghizni.

GUREV, or GURIEF, a town of Russia, in the government of Caucasus, at the mouth of the Ural or Jaik, on the Caspian sea; 172 miles E.N.E. of Astrachan. This is a fortress, and the least of those along the Jaik, but the best constructed. It has only a single gate, which leads towards the river. It consists of 140 houses, all of wood, except the governor's, and powder magazines. Its population consists of the garrison, composed of two companies of fusileers, a squadron of Cossacks, and some Astrachan merchants, who carry on a little trade with the Kirghis Tartars, who border on that country. The harbour of Gurief is one of the principal harbours of Russia. N. lat. 47° 10'. E. long. 52°.

GUREUS, in *Ancient Geography*, the ancient name of the river Kameh, or Cabul, which see. It was crossed by Alexander in his march with much difficulty, by reason of the depth and rapidity of its stream, and the nature of its bottom, which was composed of round slippery stones. Alexander's march from the Cophenes to the Gureus might probably be 100 road miles.

GUREWAR, in *Geography*, a town of Hindoostan, in Oude, on the Dewah; 30 miles N. W. of Fyzabad.

GUREZ, a town of Walachia; 20 miles W.S.W. of Kimnik.

GURGA, a town of Hindoostan, in Bahar; 18 miles S. of Rotas.

GURGENAGUR, a town of Hindoostan, in the Carnatic; 10 miles N.W. of Trinomaly.

GURGIPTING, in *Falconry*, a term used when a hawk is stiff and choaked up. Dict. Rust.

GURGISTAN, in *Geography*, a town of Persia, in the province of Farsistan; 15 miles S.E. of Jezdkast.

GURGONG, a town of Bengal; 12 miles N. of Roganatpour.

GURGOVATZ, a town of European Turkey, in the province of Bulgaria; 36 miles S.S.W. of Viddin.

GURGUDGAPOUR, a town of Hindoostan, in Oude, on the left bank of the Ganges; 56 miles W.S.W. of Kairabad.

GURGULIO, in *Natural History*, a name given by the ancients to a peculiar class of *scarabæi* or beetles; the characters of which are, that they have not a short head like the other beetles, but a long one, forming a trunk in the manner of the common flies; in this the horns or antennæ of the creature are lodged. These are divided by Lister into two kinds; the one having only one joint in this promuscis or snout, and that placed in or near the middle; the other having several placed near the end. Of the first kind we have only two species. Of the other kind, in which the promuscis has several joints at the end, we have five species; and in all these,

thefe, as well as in the former, the antennæ are inferted in the promufcis.

GURHEA, in *Geography*, a town of Bengal; 20 miles W. of Nagore.

GURIANO, a town of Africa; 40 miles S. of Tripoli.

GURIEL, a fmall town of Afia, bounded N. by Mingrelia, N.E. by Imiretta, E. by Turkifh Armenia, and elfewhere by the Black fea. It is governed by a prince, fubordinate to the Turkifh empire, and it refembles Mingrelia in foil, climate, and the manners of its inhabitants. The chief place is Gonieh.

GURIRIBA, a harbour on the coaft of Brazil. S. lat. 1°. W. long. 47°.

GURLAPAR, a town of Hindooftan, in the Carnatic; 38 miles W. of Ongole.

GURMACKTISHER, a town of Hindooftan; 40 miles E. of Delhi.

GURMADA, a town of Hindooftan, in the circar of Cuddapa; 10 miles S. W. of Combam.

GURMAH, a town of Hindooftan, in Bahar; 40 miles S. E. of Boglipour.

GURNADY, a town of Bengal; 45 miles S. E. of Mahmudpour.

GURNARD, in *Ichthyology*, a fea fifh, of which there are feveral fpecies. See TRIGLA *Gurnardus*.

GURNARD, *Grey*. See TRIGLA *Gurnardus*.

GURNARD, *Red*. See TRIGLA *Cuculus*.

GURNARD, *Sapphirine*. See TRIGLA *Hirundo*.

GURNARD, *Streaked*. See TRIGLA *Lineata*.

GURNARD, *Yellow*, or *Dracunculus*. See CALLIONYMUS *Lyra*.

GURNET POINT, in *Geography*, a cape or the N. coaft of the Ifle of Wight. N. lat. 50° 45'. W. long. 1° 11'.

GURNET *Bay*, a bay on the N. coaft of the Ifle of Wight; two miles W. of Cowes.

GUROOKA, a town of Ruffia, in the government of Ekaterinoflaf, on the Ingul; 76 miles W.S.W. of Ekaterinoflaf.

GURRAH, a town of Bengal; 64 miles N.N.W. of Midnapour.—Alfo, a town of Hindooftan, in Oude; 27 miles S.E. of Lucknow.—Alfo, a town of Hindooftan, and capital of a circar called "Gurrah Mundella," fituated on both fides of the Nerbuddah river; about 170 miles long, and from 40 to 80 broad. The town is about five miles N. of the river; 168 miles S.S.W. of Allahabad. N. lat. 23° 9'. E. long. 80° 23'.—Alfo, a circar of Hindooftan, in the country of Allahabad.

GURRAMCONDA, a town of Hindooftan, in Myfore; 73 miles N.E. of Bangalore. N. lat. 13° 47'. E. long. 78° 36'.

GURRAN ISLAND, one of the fmall Bahama iflands. N. lat. 25° 14'. E. long. 77°.

GURRY, a town of Hindooftan, in Oude; 60 miles W.S.W. of Kairabad.

GURRY-*But*, in *Rural Economy*, the name of a dung-fledge in fome places. It is a kind of fliding cart, or barrow, that is much ufed in the county of Devon, of fuch dimenfions as to be drawn by one horfe, though fometimes made larger. They are fuppofed ufeful, by Mr. Marfhall, in drawing compofts on fallows, as well as in moving earth, ftones, rubbifh, manure, &c. to fmall diftances. The fides and ends are about 18 inches in height, and fixed; the loads being difcharged by overturning them in the field. They are not by any means fo convenient as fmall fingle horfe carts.

GURT, in *Mining*, fignifies a ditch or trench for conveying water, otherwife a leat, goit, gool, &c.

GURTLER, NICHOLAS, in *Biography*, a learned Swifs Proteftant divine, was born at Bafil in the year 1654. He taught philofophy and theology, in feveral German feminaries, with great reputation; and, in 1707, he was chofen profeffor of theology in the univerfity of Francker, in Friefland. He died at that place in 1711. His principal works are "Lexicon Linguæ Latinæ, Germanæ, Græcæ, et Gallicæ;" "Hiftoria Templariorum;" "Origines Mundi;" and "Inftitutiones Theologicæ."

GURTNAMACKIN, in *Geography*, a river of Ireland, in the county of Galway, which dips feveral times, and, after a concealed courfe of two miles, rifes on the beach below high-water mark, and difcharges itfelf among the rocks in the bay of Kinvarra.

GURYA, a town of Bengal; 24 miles N. of Dinagepour.

GURYMURRY, a town of Affum; 45 miles E. of Rangamutty.

GUSDAL, a town of Norway, in the diocefe of Chriftiania; 85 miles N. of Chriftiania.

GUSHAL. See KUSHAL.

GUSINO Nos, a cape on the W. coaft of Nova Zembla. N. lat. 73° 30'. E. long. 51° 14'.

GUSIPOUR, a town in Bengal; 36 miles N.E. of Dacca.

GUSSET, in *Heraldry*, denotes one of the abatements of honour, appropriated to lafcivious, effeminate, or wanton perfons. It is formed of a line drawn from the dexter or finifter angle of the chief, and defcending diagonally to the chief point; from whence another line falls perpendicularly upon the bafe.

GUSSIAH, in *Geography*, a town of Bengal; 30 miles W. of Iflamabad.

GUSSOLA, a town of Italy, in the department of the Po; 15 miles E.S.E. of Cremona.

GUSSOLENGO, a town of Italy, in the Veronefe, on the Adige; fix miles W.N.W. of Verona.

GUST. See TASTE.

GUST is ufed by Bracton, and other ancient writers, for ftranger or gueft, who lodges with a perfon the fecond night. See UNCUTH.

In the laws of St. Edward, publifhed by Lambard, the word is written *geft*.

GUST denotes a fudden and violent fquall of wind, burfting from the hills upon the fea, fo as to endanger the fhipping near the fhore. Thefe are peculiar to fome coafts, as thofe of South Barbary and Guinea.

GUSTAF, in *Geography*, a fmall ifland in the Baltic, near the coaft of Finland, in which is a town; 28 miles W. of Abo. N. lat. 61° 35'. E. long. 21° 12'.

GUSTAF *Adolphs*, a town of Sweden, in Tavaftland; 57 miles N.E. of Tavafthus.

GUSTAN, a town of Perfia, in Couheftan; 45 miles S.S.W. of Tabas-Kiliki.—Alfo, a town of Hindooftan, in Lahore; 8 miles N.W. of Rotas.

GUSTATION. See TASTING.

GUSTATORIUS, in *Anatomy*, from *guflo*, to tafte; the branch of the inferior maxillary nerve, in which the fenfe of tafte is confidered to refide. See NERVE.

GUSTAVIA, in *Botany*, fo called by Linnæus, in compliment to Guftavus III. king of Sweden, who graciouſly beſtowed upon him a large collection of Surinam plants, preſerved in ſpirits, which afforded the materials of his diſſertation entitled *Plantæ Surinamenſes*, publiſhed at Upſal in June 1775, and reprinted by Schreber, in

Amœn. Acad. v. 8. 249.—Linn. Suppl. 51. Schreb. 474. Willd. Sp. Pl. v. 3. 846. Mart. Mill. Dict. v. 2. Gærtn. t. 138. (Pirigara; Aubl. Guian. v. 1. 487. Juff. 326. Lamarck. Illuſtr. t. 592.)—Claſs and order, *Monadelphia Polyandria*. Nat. Ord. *Myrti*, Juff.

Gen. Ch. *Cal.* Perianth ſuperior, either a ſimple wavy border, or furniſhed with ſix acute teeth, permanent. *Cor.* Petals ſix or eight, ſlightly connected, or ſomewhat imbricated at the baſe, obovate, concave, regular, nearly equal, finely downy. *Stam.* Filaments very numerous, ſhorter than the petals, connected at the baſe into a broad deep cup; anthers terminal, erect, verſatile, oblong, quadrangular, obtuſe, opening by two pores near the top. *Piſt.* Germen turbinate, depreſſed, bordered with the calyx, ſomewhat umbilicated; ſtyle conical, very ſhort, permanent; ſtigma obtuſe. *Peric.* Berry nearly globular, dry, of four, five or ſix cells, crowned with the remains of the calyx. *Seeds* ſeveral in each cell, horizontal, oblong, thick, angular, each attached by a thick folded ſtalk.

Eſſ. Ch. Calyx waved or toothed. Petals ſix or eight. Berry inferior, dry, of ſeveral cells. Seeds numerous, ſtalked, ſtyle ſimple.

1. G. *auguſta*. Linn. Suppl. 313. Pl. Surin. n. 87. Am. Acad. v. 8. 259. t. 5. (Pirigara tetrapetala; Aubl. Guian. v. 1. 487. t. 192. Japarandiba; Marg. Braſ. 109. f. 1. Piſ. Braſ. 121. f. 2.)—Calyx waved, ſcarcely toothed. Petals eight.—Native of Surinam and Cayenne, bearing flowers and fruit in September. *Stem* woody, branched, twenty or thirty feet high. The wood is pliant, fœtid when cut, ſerving chiefly to make hoops. *Leaves* a foot or more in length, elliptic-oblong, or ſomewhat obovate, acute, ſmooth, veiny, ſlightly ſerrated, nearly ſeſſile; the lowermoſt whorled, the others alternate. The veins ſtand nearly at right angles with the rib, and are connected by innumerable reticulations. *Flower-ſtalks* terminal, two or three together, much ſhorter than the leaves, ſimple, ſingle-flowered, with a pair of very ſhort claſping bracteas about the middle. *Flowers* very handſome, and fragrant like a lily, three or four inches broad, their petals white, veined with red at the baſe. *Anthers* yellow. *Fruit* reddiſh, with four longitudinal furrows, and four cells.—Aublet having miſtaken the four outer petals for a calyx, overlooking the true one, has given this ſpecies a very unſuitable name, *tetrapetala*, and has miſled thoſe who had no guide but his book, and who doubtleſs muſt have found no ſmall perplexity in making his deſcription ſquare with that of Linnæus.

2. G. *hexapetala*. (G. faſtuoſa; Willd. n. 2. Pirigara hexapetala; Aubl. Guian. v. 1. 490. t. 193. Lamarck Illuſtr. t. 592. f. *a*.)—Calyx with ſix triangular teeth. Petals ſix.—Found by Aublet in the great foreſts of Guiana, near the river of Sinemari, forty miles above its mouth. *Stem* about twenty-five feet high, its wood exhaling a cadaverous odour. *Leaves* obovate, pointed, ſlightly ſerrated, ſmooth, veiny, ſix inches long at the utmoſt. *Flower-ſtalks* about the ends of the branches, axillary, and terminal, ruſty, with a pair of ovate, nearly oppoſite bracteas about their middle. *Flowers* an inch and half broad. *Calyx* in ſix deep, equal, aſcending, triangular, acute, thick and coriaceous, ruſty teeth. *Petals* white, longer than the calyx. *Anthers* yellow. *Fruit* ſcarcely furrowed. Aublet deſcribes four cells, but there are five in his plate. We have drawn up our deſcription from one of his own ſpecimens, and ſee no reaſon to change his expreſſive ſpecific name, which the younger Linnæus meant to adopt.

Theſe magnificent plants, have not, to our knowledge, appeared, or at leaſt have not been preſerved in any garden, yet they are not too large to bloſſom in our ſtoves.

GUSTAVUS I., in *Biography*, ſurnamed *Ericſon*, or *Vaſa*, king of Sweden, born in 1490, was ſon of Eric Vaſa, and allied to the royal family. He was diſtinguiſhed in his youth as well for his learning as for his perſonal and mental accompliſhments, and on the invaſion of Sweden by Chriſtiern II. in 1518, Guſtavus was one of the ſix hoſtages whom he took back with him to Denmark. He attempted, as well by threats as by promiſes, to detach Guſtavus from the allegiance which he owed to his own country, but finding the young man ſteady to his principles, he gave orders to put him to death, though he was induced to change the brutal ſentence to impriſonment in the caſtle of Copenhagen. Eric Banner, a Daniſh nobleman, feeling compaſſion for his ſufferings, obtained leave to take him to a fortreſs in Jutland, of which he was the governor. Here he paſſed his time with ſome ſatisfaction, till he heard of the acceſſion of Chriſtiern II. to the Swediſh crown, when his heart burnt within him, and he was reſolved tō uſe every effort in reſcuing his country from ſervitude. For this purpoſe he made uſe of the indulgence granted him, eſcaped from the chace and fled to Lubec. Here he attempted to engage the regency of the city in favour of the Swedes, but they refuſed to give countenance to a party then in the loweſt ſtate of humiliation. He ſoon found that the Danes were in queſt of him, and was obliged to aſſume the habit and manners of a peaſant, and in this diſguiſe he paſſed through all quarters of their army, in a waggon loaded with hay, till he reached an old family caſtle at Sudermania. Thence he diſpatched letters to his friends, hoping to rouſe them to an attempt for the recovery of their liberty, but meeting with little ſucceſs with the great, he next tried his fortune among the peaſantry. He viſited their villages by night, harangued them at their feſtive aſſemblies, but as often as he came to the main point, the object of his wiſhes, they uniformly told him it was in vain for them to attempt to better their condition, for peaſants they were, and ſo muſt continue, whoever wore the crown. The news of the maſſacre of the ſenators at Stockholm, in which he loſt the greater part of his friends and relations, plunged him into deeper affliction, and nothing but hope, which remains unextinguiſhable in a great ſoul, could have prevented him from abandoning his deſigns in deſpair. He had one reſource left, he determined to try the patriotiſm of the miners of Dalecarlia. He penetrated the mountains of that remote province, and was obliged, for a ſcanty ſubſiſtence, to enter himſelf as a common labourer at a mine. Here he wrought within the dark caverns of the earth, but the fineneſs of his linen led ſome of his fellow labourers to ſuſpect that he was a perſon of rank in diſguiſe. The rumour ſpread, and a neighbouring gentleman recognized him, to his aſtoniſhment, for an old univerſity friend. He perſuaded him to become an inmate of his houſe, but when Guſtavus made him the confidant of his bold deſign, his friend, who had been extolling the courage of his countrymen, and their abhorrence of the preſent tyranny, ſtarted with horror at the propoſal. By another perſon he had been nearly betrayed, and was obliged to conceal himſelf in the family of a neighbouring clergyman, on whoſe fidelity he could rely. By the advice of this friend Guſtavus repaired to Mora, where an annual feaſt of the ſurrounding peaſantry was held. There, as his laſt reſource, he diſplayed with ſo much native eloquence and energy the miſeries of his country and the tyranny of Chriſtiern, that the aſſembly inſtantly determined to take up arms, and adopted

him

him as their leader. He immediately, while their hearts were glowing with an ardent patriotism, led them againſt the governor's caſtle, which they ſtormed, and took or deſtroyed the whole garriſon. Succeſs increaſed his forces, multitudes were ready to enliſt under the banners of the conquering hero, and Guſtavus, at the head of his little army, magnified by the fears of the enemy, overran the neighbouring provinces, defeated the archbiſhop of Upſal, and advanced to Stockholm. The infamous Chriſtiern, who had in vain attempted to ſtop his progreſs by the threat of maſſacring his mother and ſiſters, at length put his menace into execution. The cruel deed animated Guſtavus to a ſeverer revenge. He aſſembled the ſtates of Sweden at Wadſtena, where he was unanimouſly choſen adminiſtrator, and after a variety of military tranſactions, he laid ſiege to Stockholm. Chriſtiern was glad to withdraw into Germany, the Danes were completely expelled from Sweden, and Guſtavus was raiſed to the throne in the year 1523. Stockholm ſurrendered, and peace and order were reſtored to the long afflicted country. Guſtavus, when ſettled on his throne, appeared as the encourager of the reformation, which had begun to make its way in Sweden: he cauſed the ſcriptures to be tranſlated into the native language, which had the effect of expoſing the corruptions of popery to popular detection. At length, finding himſelf ſtrong enough, he openly profeſſed the principles of the reformed religion, and propoſed the reſumption of the crowned lands uſurped by the church, and the abolition of the ſale of indulgences. Theſe points he carried, but was much mortified by a revolt of his favourite Dalecarlians, who were zealouſly attached to all the ancient inſtitutions, and were artfully inflamed by the ſuggeſtions of the prelates. At different periods, diſputes aroſe between Guſtavus and the kings of Denmark, but the Swediſh king generally came off with advantage over his enemies; and, owing to a conſpiracy formed by the Lubeckers againſt Guſtavus, a war enſued, in which Denmark became an ally of Sweden. In 1542 Guſtavus made an alliance with Francis I. of France, and in the ſame year he had ſufficient addreſs to render the crown of Sweden hereditary in his own family, and to procure the nomination of his eldeſt ſon Eric as his ſucceſſor. The aſſembly who ſanctioned theſe important laws, took an oath for the maintenance of the reformed religion, without the toleration of any other, ſo that the change of religion was fully completed. The king, from this time, bent his attention upon the encouragement of learning, commerce, the arts and ſciences. He was deſirous of giving additional ſplendour and authority to his eldeſt ſon by ſome potent matrimonial alliance. With this view he cauſed propoſals to be made to Elizabeth, queen of England, but while the affair was in agitation, he was attacked by a ſlow fever, of which he died in the ſeventieth year of his age. He had been thrice married, and left ſeveral children. He has been regarded by hiſtorians as one of the greateſt and beſt of ſovereigns of his age and country.

GUSTAVUS, ADOLPHUS, king of Sweden, who, for a ſhort time, was regarded as the hero of Europe, was grandſon of Guſtavus Vaſa, and ſon of Charles IX. He was born in 1594, and received an education ſuitable to his birth and his expectations. At an early age he was diſtinguiſhed for enterpriſing valour. In 1611 he ſucceeded to the crown; and ſo great was his reputation that it was agreed that his minority ſhould terminate at an age earlier than the law had preſcribed, and the reins of government were freely committed to his hands. He gave an admirable ſpecimen of his judgment by chuſing, for his prime miniſter, the great chancellor Oxenſtiern, one of the ableſt men that ever filled the office in any kingdom. Guſtavus aſſembled the ſtates in 1612, and reſumed the crown-grants, in order to enable him to carry on the war in which Sweden was involved with Denmark, Ruſſia, and Poland. Having terminated this, as far as related to the firſt two powers, to his ſatisfaction, he began moſt earneſtly to attend to affairs of domeſtic policy, among which were the eſtabliſhment of a commercial ſociety at Stockholm, the regulation of the univerſity of Upſal, and the abridgment of the proceſſes at law. In 1629, after various ſucceſſes, he concluded a truce with the Poles, by which he was left in poſſeſſion of Memel, Pillau, Elbing, Brunſberg, and his conqueſts in Livonia. He now panted for greater glory in the field of war; and having taken offence at the conduct of the emperor, and being, at the ſame time, deſirous of protecting the Proteſtants in Germany, he entertained the project of invading the imperial dominions, and contending, on their own territories, with a power, at that period, at the ſummit of military glory. At firſt the idea was oppoſed by the ſenate; but the king's ardour and eloquence overcame all oppoſition. Every aid was voted him, and an army of ſixty thouſand men, with a large navy, were put at his diſpoſal. England and France favoured his deſign; and, in June, 1630, he embarked on this great enterpriſe. His early ſucceſſes ſtruck the emperor with conſternation, and cauſed the electors of Brandenburg and Saxony to form a treaty of alliance with him. It was now that Ferdinand found, to his coſt, that Guſtavus was not, as he had once denominated him, a king of ſnow, who would melt away as he approached the warm regions of the ſouth—but an avalanche, increaſing in ſize and force as he rolled onwards. As he advanced into Saxony he was attacked by the great Tilly, who was repulſed; and the elector gladly formed an alliance with Guſtavus for his own protection. Tilly had inveſted Leipſic; and, on the 7th of September, 1631, Guſtavus led the united Swediſh and Saxon army into the field. The monarch, diſtinguiſhed by a green feather in his hat, led the charge againſt the braveſt of the enemy, and he gained a complete victory, the conſequences of which were the ſubverſion of all the emperor's meaſures, and an acceſſion to the renown of Guſtavus, whom the Proteſtants now began to look upon as their great champion and deliverer. After this he reduced many places in that part of Germany, and, in 1632, prepared to enter Bavaria. Here he was ſome times ſucceſsful; but upon the death of Tilly, he was oppoſed by the celebrated Walleſtein, who had collected an army ſuperior to that commanded by the king of Sweden. For ſome time the two armies lay encamped oppoſite to each other. At length Guſtavus made an attack and was repulſed; and, on the 16th of November, on the plains of Lutzen, a great action commenced, in which Guſtavus was ſhot in the arm while fighting at the head of a body of cavalry. For ſome time he diſregarded the pain, but the loſs of blood rendered him faint; and he was preparing to leave the field, when he was killed by a ſquadron of imperial cuiraſſiers. He ſunk, however, in the arms of victory, in the 38th year of his age, leaving behind him an only child, the celebrated Chriſtina. He has been characteriſed as the terror of Auſtria, the hope of the Proteſtant religion, and the admiration of all Europe. Few ſovereigns have poſſeſſed more of the qualities of a truly great prince. He was frank, acceſſible, generous, humane, and juſt; a lover of learning, and the patron of learned men. He was a maſter in the art of war, to which he contributed ſeveral inventions and improvements. He made the Swedes the beſt ſoldiers in

Europe, and trained a ſet of generals who long maintained the national renown. Many of our own countrymen ſerved under him, and brought home, and practiſed the diſcipline which they had learned.

Gustavus III. king of Sweden, ſon of Adolphus Frederic and Louiſa Ulrica, ſiſter of Frederic II. king of Pruſſia, was born on the 24th of Jan. 1746, and educated under the care of the celebrated count Teſſin. He ſucceeded his father in the year 1771; and at the period of his acceſſion to the throne, the ſupreme authority, in conſequence of abuſes which had crept into government, reſided in a tumultuous aſſembly of four orders, into which were admitted tradeſmen, and even peaſants. The ſtatutes were ſigned by the king, and the ordinances iſſued in his name, yet he poſſeſſed no negative; and however odious particular meaſures might be to him, ſtill, if they were preſſed in the diet, they were regarded as laws; and, ſhould he refuſe to ſign the decrees, his name was affixed by a public ſeal. The king was, in ſhort, only an inſtrument in the hands of one or two great parties, which divided and governed the kingdom among themſelves. Guſtavus III. reſolved to emancipate himſelf and the kingly office from this ſtate of degradation, or to periſh in the attempt. He was a wary, as well as a bold and determined man; and he concerted meaſures ſo dexterouſly, that the plan was carried into execution in the courſe of a few hours, and without the leaſt bloodſhed. An account of this revolution will be found under the article Sweden. The king himſelf drew up the form of the new conſtitution, by which he had the power of convoking and diſſolving the aſſembly of the ſtates as often as he pleaſed. He had the ſole power over the army, navy, and finances. In caſe of an invaſion, or other urgent neceſſity, he might impoſe taxes of his own accord; and the diet could deliberate on no ſubject except thoſe which were firſt propoſed by the king. By theſe, and other articles of a ſimilar tendency, did Guſtavus become one of the moſt deſpotic monarchs, from being the moſt limited and even abject of ſovereigns. The power thus obtained, it has been generally admitted, was employed for the good of his ſubjects. He took care that the law ſhould be adminiſtered with ſtrict impartiality to the poor and to the rich; and made a ſevere example of ſuch judges as were proved to have made the ſeat of juſtice the ſource of venality. He was the encourager of commerce, was a liberal and enlightened patron of learning and ſcience, and laboured ſtrenuouſly to introduce into his kingdom the moſt important improvements in agriculture that had been adopted in other countries. Having attended to the arts of peace, he began to conſider how he could beſt provide for the reſtoration of his fleet and army, which he found in a feeble ſtate. He accordingly introduced new and very ſalutary regulations in both departments; he augmented the pay of the officers, and provided for the maintenance of thoſe who had ſerved the ſtate, when they were, by age, or other infirmities, incapable of farther public duties. Deſirous of diffuſing learning among his ſubjects, he gave every encouragement to the purſuit of the arts and ſciences, and to the belles lettres. He procured a good tranſlation of the bible by eminent ſcholars; and he invited men of talents to employ their pens in the production of elementary books on all ſubjects. Without following Guſtavus in the wars in which he engaged, and which will be more conveniently noticed in the article already referred to, we may obſerve, that though he was extremely popular among the lower claſſes, he met with great oppoſition from the nobility, the heads of whom were ſo implacable in their reſentment, on account of the revolutions, that no favours, preferments, nor honours, ſeemed capable of curing their animoſity. In the diet which met in January 1789, the uſual, and, in general, unmeaning, congratulations and compliments were paſſed; but it was ſoon perceived that the nobles were not only far from being diſpoſed to coincide with the king's views, but that they paid but little regard to the terms on which they ſtood with him. They ſeemed anxious to effect a counter revolution; they took every opportunity of thwarting his meaſures, and of treating with contempt thoſe who were particularly favoured by his majeſty. He had appointed count Lowenhaupt to be marſhal of the diet; whom they ſo groſsly inſulted that he abſented himſelf from his duty. In February the king, in perſon, appeared in the aſſembly, and demanded ſatisfaction for the inſult offered to his marſhal. A violent altercation enſued between his majeſty and the nobles, and the latter roſe in a body and quitted the aſſembly, leaving the king and the other ſtates together. For three days Stockholm was in a ſtate of confuſion, but on the fourth, *viz.* on the 20th of February, the houſes of all the nobility were ſurrounded at the ſame inſtant, and the nobles themſelves being arreſted were ſent priſoners to the caſtle of Frederickſhoff. From this moment Guſtavus aboliſhed the ſenate and ſupplied its place by a new court, which was endowed with large powers, but ſubject entirely to the king. The nobles continued ſtill diſcontented, and a conſpiracy was planned againſt Guſtavus under his own roof; he had entered into the alliance that was formed againſt the revolutionary government of France; and to raiſe an army which he was to lead in perſon, to co-operate with the emperor and king of Pruſſia, he was obliged to negociate large loans, and to impoſe on his ſubjects heavy taxes. The nobles took advantage of that circumſtance to prejudice the minds of many of the people againſt the ſovereign; who, with all his defects, had laboured ſo long for their good. On the 16th of March 1792, he received an anonymous letter, warning him of his immediate danger from a plot that was made to take away his life, requeſting him to remain at home, and to avoid balls and other aſſemblies for a year, and aſſuring him, that if he ſhould go to the maſquerade for which he was preparing, he would be aſſaſſinated that very night. The king read the note with contempt, and at a late hour entered the ball room. After ſome time he ſat down in a box by count d'Eſſen, and obſerved that he was not deceived in his contempt for the letter, ſince had there been any deſign againſt his life, no time could be more favourable than that moment; he then mingled, without apprehenſion, among the crowd, and juſt as he was preparing to retire, in company with the Pruſſian ambaſſador, he was ſurrounded by ſeveral perſons in maſks, one of whom fired a piſtol at the back of the king, and lodged its contents in his body. A ſcene of dreadful confuſion immediately enſued. The conſpirators, amidſt the general tumult and alarm, had time to retire to other parts of the room, but one of them had previouſly dropped his piſtols and dagger cloſe by the wounded king. A general order was given to all the company to unmaſk, and the doors were immediately cloſed, but no perſon appeared with any diſtinguiſhing marks of guilt. The king was conveyed to his apartment, and the ſurgeon, after extracting a ball and ſome ſlugs, gave favourable hopes of his recovery. The reports of his medical attendants ſoon proved to be fallacious, and on the 29th of March he expired, and on opening his body there were found within the ribs a ſquare piece of lead and two ruſty nails. The king had by his will appointed a council of regency, but convinced, by recent experience, how little de-

pendance

pendance was to be placed on the attachment of his nobles, and aware of the neceſſity of a vigorous government, in times of ſuch difficulty and danger, he appointed his brother, the duke of Sudermania, ſole regent, till his ſon, then a minor, ſhould attain the age of eighteen years. In his dying moments he deſired that all the conſpirators, except the perſon who perpetrated the bloody deed, might be pardoned. Guſtavus III. was a prince of excellent talents. To a great fund of natural eloquence, he united the moſt inſinuating manners, and, it is ſaid, that the extent of his knowledge and the ſolidity of his judgment excited the admiration of thoſe who had acceſs to his converſation. He had ſeen much of the world, was well acquainted with mankind, and poſſeſſed ſufficient ſagacity to profit by his obſervations, and to apply them to the purpoſes of government. Guſtavus was a fine writer, of which there were abundant proofs in the private letters and memorials drawn up by his own hand, as well as in different pieces that have been printed, which, though anonymous, were known to be his, particularly one, the object of which was to expoſe the licentiouſneſs of the private life of Catherine II., and the arrogance of her inordinate ambition. He was author of ſeveral plays, written for the national theatre, which were well received, and the moral ſentiments of which are worthy of the prince and legiſlator.

GUSTEN, in *Geography*, a town of Germany, in the circle of Anhalt Cöthen, on the Wipper; 12 miles W. of Cöthen. N. lat 51° 50'. E. long. 11° 45'.

GUSTI, a town of Perſia, in the province of Farſiſtan; 75 miles N. of Schiras.

GUSTO, in *Painting* and *Sculpture*, a word adopted from the Italian, and ſignifying the taſte or ſtyle in which a work of art is executed or conceived. Although in its native idiom it is uſed both for good and bad ſtyle, for the grand or the mean; with us it is ſeldom, if ever, employed, when the ſtyle of a work is of an inferior order. It is only when it juſtifies the higheſt approbation, and we can with propriety couple another Italian word with it, and deem it of the *grande guſto*, that cuſtom authoriſes the uſe of it in this country.

The ſtyle of Michael Angelo is in the guſto grande, wherein nature is enlarged upon, is inflated, and in danger of being caricatured, if the artiſt is not of the firſt claſs. The works of Goltzius the painter, who endeavoured to uſe this ſtyle and did not feel it, but only made bad and diſtorted imitations of M. Angelo, are a ſufficient proof how near the abyſs of affectation the grande guſto verges: where it is purely attained, the art is exalted by it, and nature preſented to the eye and the mind with inconceivably far greater force than in its ordinary appearances.

GUSTROW, in *Geography*, a town of the duchy of Mecklenburg, ſituated on the river Nebel, famous for its beer, which forms the principal article of its trade; 16 miles S. of Roſtock. N. lat. 53° 48'. E. long. 12° 3'.

GUSUM, a town of Sweden, in Eaſt Gothland; 22 miles E.S.E. of Nordkioping.

GUT-TIE, in *Rural Economy*, the name of a diſeaſe of the bowel kind, principally in calves that have been caſtrated, and which by ſome is ſuppoſed the conſequence of an improper method of performing the operation, a ſtoppage being produced in the inteſtines, the reſult of which is often mortification, and of courſe the ſpeedy deſtruction of the animal. It is aſſerted to be a diſeaſe very common in the county of Hereford.

Beſides the ſymptoms of an obſtruction in the bowels, there is a diſcharge of bloody mucus that is attended with great heat and fever. The animal kicks at its belly, lies down and groans. It is found ſometimes to attack the animals when they are fully grown. In the view of removing the obſtruction in the bowels, ſtrong ſaline laxative medicines have been employed with oil. And it is probable that caſtor oil would be found beneficial in the ſame intention. But in the diſtrict noticed above, it is uſual to have the following operation performed in order to the removal of the complaint. An inciſion is made in a perpendicular manner, four inches below the third vertebra of the loins, over the paunch or ſtomach, introducing the hand to diſcover the affected part, and remove the ſtring that is the cauſe of it, the beaſt being ſupported during the time in an upright ſituation.

GUTA, in *Geography*, a town of Hungary, in the iſland of Schit, near the conflux of the Waag and the Danube; 30 miles S.E. of Preſburg.

GUTENHAG, or DOBRODCIN, a town of Sileſia, in the principality of Oppeln; 21 miles E. of Oppeln. N. lat. 50° 42'. E. long. 18° 28'.

GUTERA, a town of Sicily, in the valley of Mazara; 20 miles N. of Girgenti.

GUTIGUI, a town of Hindooſtan, in Viſiapour; 20 miles N. of Anamſagur.

GUTKIRAS, a town of Aſiatic Turkey, in the government of Sivas; 10 miles N.W. of Amaſia.

GUTLAND, a town of Pruſſia, in Pomerelia; 15 miles S.S.E. of Dantzic.

GUTS. It is obſerved, in the diſſections of many of the beaſts of prey, that the guts are very remarkably ſhort in compariſon of thoſe of other animals. The lion and the lynx are of this number; the guts being in theſe only of three times the length of the body. This argues ſpeedy digeſtion, and a great voracity of the creature. See INTESTINES.

GUTTA, a Latin term for what in Engliſh we call *Drop*.

GUTTA, in *Geography*, a town of Bengal; 20 miles S.W. of Doeſa.

GUTTA *Roſacea*, or *Roſea*, in *Medicine*, literally ſignifying *roſy drop*, a term applied to thoſe eruptions of red pimples which occur in the face, are very ſlow in their progreſs and changes, and continue to diſfigure the countenance frequently during a long courſe of years. The cauſe of the eruption is, in ſome inſtances, altogether inſcrutable; the diſeaſe appears to originate from a peculiar ſtate of the conſtitution, which is occaſionally obſerved to be hereditary. Moſt commonly, however, it is connected with a morbid condition of the liver or ſtomach, or is excited by the direct operation of certain articles of food or drink, taken under particular circumſtances of the body. The gutta roſea is a frequent occurrence in drunkards, and is uſually conſidered as indicative of the diſeaſe in the liver, which the habit of ſpirituous or vinous potation commonly induces. This is the *gutta roſea hepatica* of Dr. Darwin. But it often alſo ariſes from drinking cold water, eating raw turnips, or other cold vegetables, when the perſon is much heated and perſpiring after exerciſe. The ſtomach becomes painful with indigeſtion and flatulency, and in a day or two an eruption appears on the face, and continues with ſome relief to thoſe ſymptoms, but not with entire relief; as both the pimpled face and indigeſtion are liable to continue even to old age. This conſtitutes the *gutta roſea ſtomatica* of Dr. Darwin. (See his Zoonomia, Claſs II. i. 4, and IV. i. 2.) The colour of the eruption in the latter ſpecies is leſs deep than in the hepatic ſpecies; and the preſence of the ſtate of indi-

geſtion, as well as the patient's known habits in reſpect to drinking, may aſſiſt us in diſcriminating the nature of the diſorder.

The cure of this eruption, from whatever cauſe it may have ariſen, is extremely difficult; and local applications to the affected part, or internal remedies, are often equally inert. Where the eruption is ſympathetic of diſeaſed liver, the reſult of intemperance, it is obvious, that the firſt ſtep of the cure muſt be to correct the exciting cauſe, and then to uſe gentle laxatives, eſpecially of the mercurial claſs, with a view to reſtore the hepatic functions. And, in like manner, when the complaint is accompanied by obvious derangement of the ſtomach and bowels, medicines, which the nature of that derangement may indicate, muſt be reſorted to: light and nutritious diet, as of milk, and the farinaceous vegetable matters; the warm bath; exerciſe; the mineral waters, &c. will form the auxiliary part of the plan of treatment. Various topical applications are recommended by different practitioners, and, as the unſightlineſs of theſe ſpots on the face excites an uncommon anxiety in the patient to get rid of them, the herd of advertiſing quacks have never failed to find an abundant harveſt in the ſale of their various lotions and coſmetics. Theſe generally conſiſt of ſolutions of ſome of the metallic ſalts, eſpecially of thoſe of lead, zinc, and mercury, or of ſimple ſaponaceous mixtures. It cannot be doubted, that of the former ſome occaſionally ſucceed, though they much more frequently fail, and one will ſometimes prove uſeful, where others have been altogether inefficacious, when no ſatisfactory account of theſe various operations can be given. It has been alleged, however, that the ſudden removal of theſe ſpots by ſtrong metallic lotions has frequently been followed by other diſeaſes of more danger. Dr. Darwin has related a few inſtances of the ſuppreſſion of the eruption by ſaturnine lotions, and even by an alum poultice, in which epilepſy and palſy ſpeedily enſued. This phyſician affirms, that bliſtering the face all over the eruption, beginning with a part only, has appeared to him to ſucceed better than any other mode of practice. He recommends, alſo, the taking of five grains of rhubarb, and a quarter of a grain of emetic tartar every night for many weeks. The various herbs, to which the older phyſicians attributed the qualities of correcting the morbid humours, on which they ſuppoſed theſe eruptions to depend, and of purifying the ſkin, ſuch as fumitory, ſaccory, &c. are now conſidered as poſſeſſing no efficacy: and the various complicated ointments and lotions which they employed, perhaps receive as much praiſe as is due to them, when they are called harmleſs. See an abundant variety of theſe in Turner's Treatiſe on Diſeaſes of the Skin, part ii. chap. 1.

Gutta *Serena*, or *Amauroſis*, denotes, in *Surgery*, a ſpecies of blindneſs, in which the ſenſibility of the retina and optic nerve is either partly, or entirely loſt. It is a diſorder, the exiſtence of which is made out with much more difficulty than is commonly imagined, when there is no viſible defect in the eye, and we have nothing more than the patient's aſſurance that he has loſt the faculty of ſeeing things. Almoſt all the palpable ſymptoms of the complaint are fallacious, and not to be truſted. It is uſually aſſerted, that the pupil of an eye, affected with amauroſis, is preternaturally dilated and motionleſs, while it ſtill retains its ordinary tranſparency and blackneſs. This is, indeed, the ſtate of numerous caſes; but not of all. In the moſt complete and incurable gutta ſerena, the pupil is not unfrequently of its natural ſize, and occaſionally it is even preternaturally ſmall and contracted. Although it is generally incapable of motion in the preſent diſeaſe, this is not invariably the caſe. In certain inſtances, the iris not only poſſeſſes its natural motion, but is capable of moving with uncommon activity, ſo that, in a very moderate light, it will contract in an unuſual degree, and nearly cloſe the pupil.

Nor can any certain concluſions be drawn from theſe various conditions of the pupil in the gutta ſerena, with regard to the particular nature and character of the complaint. For inſtance, the moveable or immoveable ſtate of the pupil can neither be conſidered as a favourable or unfavourable circumſtance in the caſe. Sometimes an amauroſis may be cured which is attended with a pupil extraordinarily dilated, and entirely motionleſs. Sometimes the diſorder proves incurable, notwithſtanding the pupil is of its proper ſize, and capable of motion. There are likewiſe examples, in which the pupil recovers its moveableneſs in the courſe of the treatment, although nothing will ſucceed in re-eſtabliſhing the ſight.

The pupil of an eye, affected with amauroſis, ſeldom exhibits the clear ſhining blackneſs, which is ſeen in a healthy eye. In general, it is of a dull, glaſſy, horn-like blackneſs, which alone is frequently enough to appriſe the experienced practitioner of the nature of the diſeaſe. Sometimes the colour of the pupil inclines towards green. On other occaſions, this opening ſeems thick, white, and cloudy, ſo that the complaint might eaſily be miſtaken for the beginning of a cataract. This error, into which unexperienced ſurgeons are liable to fall, may eaſily be avoided, by paying attention to the following circumſtances. The miſty appearance is not ſituated cloſe behind the pupil, in the poſition of the cryſtalline lens; but frequently is manifeſtly deeper in the eye. Nor is it in proportion to the loſs of ſight, the patient being quite blind, while the miſty appearance is ſo trivial, that, if it aroſe from an opacity of the cryſtalline lens, it could at moſt only occaſion a ſlight weakneſs and obſcurity in viſion. It muſt be acknowledged, that it is more difficult to avoid miſtake, when a beginning amauroſis is accompanied with this cloudineſs in the eye, and conſequently, when the degree of blindneſs ſeems to bear ſome proportion to the degree of miſtineſs in the pupil. However, in this caſe, the true nature of the diſeaſe may generally be known by conſidering, that, though the patient's ſight is weak, it is not rendered faulty by an appearance of miſt before the eyes, which latter circumſtance is always complained of by perſons who are beginning to be afflicted with cataracts, not to mention that there are uſually preſent ſeveral other ſymptoms which excluſively belong to the gutta ſerena.

Sometimes the interior of the eye, a good way behind the pupil, ſeems quite white. A concave white ſurface may be remarked, upon which blood-veſſels may be plainly ſeen ramifying. In particular inſtances this white ſurface extends over the whole back part of the eye; while, in other caſes, it only occupies a half or a ſmall portion of it. It is believed that the retina itſelf is the occaſion of this appearance, and indeed, this ſeems to be the real caſe. The appearance, which is at firſt miſty, and at length quite white, occupying a deep ſituation in the eye, ariſes from the retina, which, in this caſe, is deprived of its natural tranſparency, and becomes externally viſible. See Haller, Element. Phyſiol. tom. v. p. 469.

According to Richter, a degree of ſquinting is the only one ſymptom, which is inſeparable from amauroſis. This obliquity of ſight has alſo been particularly noticed by Mr. Hey in the Medical Obſervations and Inquiries. The patient not only does not turn either eye towards any object in

in ſuch a manner, that the object looked at is in the axis of viſion; but he alſo does not turn both his eyes towards the ſame thing. This, ſays Richter, is the only ſymptom which we can truſt in thoſe examples, in which confidence ſhould not be put in the mere aſſurance of the patients, that they cannot ſee.

The gutta ſerena originates with very various ſymptoms, and in exceedingly different ways. Richter thinks it probable that this variety, attendant on the beginning of the diſeaſe, depends upon ſome difference in the cauſe of the complaint, and indicates the propriety of having variety in the plan of treatment. Sometimes the patient loſes his ſight quite ſuddenly; while, in other inſtances, the power of ſeeing diminiſhes ſo ſlowly, that months and even years elapſe before the diſeaſe attains the worſt degree. Sometimes the gutta ſerena commences with ſeveral ſymptoms, which ſeem to betray an increaſe of ſenſibility in the eye, or ſome irritation affecting this organ. In moderately light places, the patient can diſcern things very well; but in a great light he is not able to ſee at all. The eye is ſometimes ſo ſenſible, that a ſtrong light will make it weep, and become painful. Patients of this deſcription ought always to wear a ſhade, however bad their ſight may be. Sometimes the gutta ſerena originates with ſymptoms of weakneſs and diminiſhed irritability. The ſight is cloudy, and the patient finds that he can ſee better in a light than a dark ſituation. He feels as if ſome dirt, or duſt, were upon his eyes, and conſequently often wipes them. His power of viſion is greater after meals than at the time of faſting. His ſight is always for a ſhort time plainer after the external uſe of tonic remedies, ſuch as hartſhorn, cold water, &c. Richter informs us of a perſon who was nearly quite blind, but was always able to ſee very well for the ſpace of an hour, after drinking champaigne wine. He alſo mentions a woman who had entirely loſt her ſight, who was in the habit of having it reſtored again for half an hour, whenever ſhe walked a quick pace up and down her garden. This author likewiſe acquaints us with the caſe of a lady who had been blind for ſome years, but experienced a ſhort recovery of her ſight on having a tooth extracted.

Sometimes, as Richter obſerves, the ſymptoms appear to indicate a preternatural accumulation of the humours of the eye. The patients complain of a tenſion in the eye-ball, which is frequently very irkſome. As often as this ſenſation is exceedingly great, the eye-ſight is weak, and whenever it ſubſides, the patient is again able to ſee better. The eye-ball feels hard, and indeed frequently ſeems ſwollen, ſo that the ſtate of the organ ſomewhat reſembles that which takes place in the hydrophthalmia. When a cataract is complicated with a gutta ſerena, the vitreous humour is ſometimes found, in operating for the firſt diſeaſe, to be preternaturally thin, the eye being, as it were, in a dropſical ſtate. The blood-veſſels of the conjunctiva are occaſionally enlarged, the patient ſees black ſpecks, net-like appearances, ſtreaks, ſnake-like figures, &c. It ſeems as if, in this caſe, the blood-veſſels of the retina and choroides were in the ſame varicoſe ſtate as thoſe of the conjunctiva, ſo as to make preſſure upon the firſt of theſe membranes. That the veſſels are thus dilated is rendered probable by the bleeding, which is apt to occur in the eye in operating for cataracts complicated with the gutta ſerena.

In certain inſtances the eye ſeems to be acted upon by ſome kind of irritation; the patients ſee ſeveral moving objects of different colours, particularly ſhining, fiery ſpots, flames, and rays of light. Sometimes amaurоſis ariſes after violent inveterate ophthalmies and head-aches. Some patients, before the diſeaſe, are repeatedly afflicted with catarrhs, which ceaſe as ſoon as the gutta ſerena is formed. Richter ſtates that the noſe then becomes unuſually free from moiſture. Some patients of this kind have been known to regain their ſight for a ſhort time, on a copious diſcharge of mucus ſpontaneouſly taking place from the noſe. Paying diligent attention to theſe various circumſtances during the origin of the diſorder, ſays Richter, will often be of great aſſiſtance to the practitioner in chooſing a method of treatment, when all other indications are abſent.

The diſeaſe commonly makes its attack upon both eyes at once, and even in thoſe occaſional inſtances in which only one is deprived of ſight, the other rarely continues for a long time ſound. The diſorder generally extends over the whole eye; but ſometimes only a half of the organ is affected, the caſe being then named *amauroſis dimidiata*. In the firſt example, the patient is quite blind; in the ſecond, he can diſcern the half of objects. Sometimes the malady ſeems to be confined to a ſingle little ſpot in the eye, in which caſe the patient is conſcious of having before the retina an immoveable black ſpeck. It is to this particular inſtance that ſome pathologiſts apply the term *ſcotomia*. Alſo patients, who are wholly blind, ſometimes have a ſmall part of the retina, which is ſtill ſuſceptible of the impreſſion of light, and is uſually ſituated towards one ſide of the eye. (See Hey in Medical Obſervations and Inquiries, vol. v.) Richter notices that in one man, who was in other reſpects entirely bereft of viſion, this ſenſible part was ſituated obliquely over the noſe, and ſo ſmall, that it was always a conſiderable time before its ſituation could be diſcovered; he adds, that it was alſo ſo ſenſible, as not only to diſcern the light, but even the ſpire of a diſtant ſteeple. According to this author, it is the centre of the eye which ſeems to be the firſt and moſt ſeriouſly affected in the gutta ſerena. Hence the generality of patients who have a beginning, imperfect amauroſis, can always ſee objects which are to one ſide better than thoſe which are immediately before them.

The gutta ſerena is ſometimes an intermittent diſorder, now making its appearance, and now ſubſiding again, repeatedly. In certain examples, as Richter remarks, the diſorder prevails at particular times, commonly all day till a certain hour, ſometimes from one day till the next, and occaſionally, at a ſtated time every month. The attacks of the complaint ſometimes take place at indeterminate periods. Now and then, ſome other morbid affection is aſſociated with the impairment of ſight. Richter mentions a man who became blind at twelve o'clock in the day, when the upper eyelid uſed alſo to hang down, in conſequence of being affected with paralyſis. The attack always laſted twenty-four hours. On the following day, at twelve o'clock, the ſight uſed to return, and the patient then ſuddenly regained the power of raiſing the eyelid. He would continue thus able to ſee for the ſpace of the next twenty-four hours. Whenever he took bark, the diſeaſe was regularly doubled, that is to ſay, the man then alternately remained blind forty-eight hours, and afterwards retained the power of ſeeing things only twenty-four. In another patient cited by this experienced ſurgical writer, the aqueous humour during the blindneſs always became diſcoloured, whitiſh, and turbid, but regularly recovered its tranſparency, on the ceſſation of the attack. Richter ſtates that the periodical amauroſis commonly depends upon ſome gaſtric irritation, the ſtimulus of worms, or irregularity in the menſtrual diſcharge. Sometimes a periodical blindneſs is the form in which a lurking intermitting fever affects a patient; and ſometimes it is plainly a ſymptom of a decided ague, the patient becoming affected

affected with an ordinary intermittent, and blind during every paroxyſm; but always regaining his ſight as ſoon as each fit is over.

There cannot be any doubt that in the gutta ſerena, the immediate organ of ſight is principally affected, the proximate cauſe of that diſeaſe conſiſting of a paralyſis of the optic nerve and retina. That ſuch is the nature of the diſorder is ſhewn to be in the higheſt degree probable, by the blindneſs being occaſioned by ſuch cauſes as produce paralytic affections of other parts, and by its frequently being curable by the ſame remedies as are known to relieve paralyſis in other ſituations.

The manifold ſhadowy, black, and coloured objects, and ſhining fiery appearances which hover before the eyes of patients labouring under a gutta ſerena, alſo make it ſeem likely that the cauſe of the diſeaſe chiefly affects the retina and optic nerve. The pale white appearance which is frequently obſervable at the bottom of an eye afflicted with amauroſis, can only be derived from the retina, of which membrane it indicates ſome diſeaſe. Sometimes indeed, ſays Richter, the optic nerves have actually been found in an unnatural ſtate, as for inſtance, ſhrivelled and conſiderably ſhrunk. He ſtates that aqueous veſicles, earthy concretions, and other ſorts of indurations, have been diſcovered near the optic nerves, in diſſecting ſubjects, who, before their deceaſe, had been blind with amauroſis. The thin ſtate in which the vitreous humour is ſometimes found in caſes of gutta ſerena, is to be regarded as an effect, and not the cauſe of the diſeaſe. Richter's Anfangſgründe der Wandarzneykunſt, vol. iii. chap. 14.

Before treating of the different cauſes of the gutta ſerena, it ſeems proper to detail the ordinary ſymptoms of the diſeaſe. When the patient is firſt attacked, his ſight gradually grows weaker, he feels as if a gauze, or ſpider's web were drawn over his eyes, and imagines he ſees a white ſurface ſtudded with black ſpecks, which he endeavours to wipe away. The pupil of the eye gradually loſes its brilliancy, and diſtends itſelf much beyond the natural ſize; and if the patient's eye be cloſed, the upper eyelid gently rubbed, and then ſuddenly opened to the light, the pupil will contract itſelf very little, if at all. The ſight grows weaker and weaker, ſpectacles and convex glaſſes are of no ſervice, and the patient, generally ſpeaking, ſees worſe in the open daylight, than in a dark ſituation. While the patient is at all conſcious of the impreſſion of the rays of light, or while a certain power of ſeeing ſtill continues, the diſeaſe is called the *imperfect* or *incomplete amauroſis*; but when the patient is wholly inſenſible of the ſtimulus of light, the diſorder is termed *perfect* or *complete*.

Schmucker remarks, that although the *complete* gutta ſerena is generally a gradual diſeaſe, there are caſes in which it comes on without being preceded by the above-mentioned circumſtances. Theſe caſes, he ſays, have frequently fallen under his inſpection, and been more eaſy of cure, than when the affliction has taken place in a more gradual way. In ſuch inſtances, the ſight is totally loſt, the patient can diſtinguiſh no object whatever, the pupil of the eye is uncommonly enlarged, and if the eye be rubbed, and then opened, and expoſed to the light, that opening in the iris remains fixed, and incapable of contraction. A lighted candle may even be held to the patients' eyes, without exciting ſenſation. The pupil now loſes its ſhining black gloſs, and grows pale, ſo that a ſkilful practitioner can perceive the difference, without being near the patient. Such perſons uſually have an unhealthy and timid look. See Schmucker's Vermiſcht. Chirurgiſch. Schriften.

According to Richter, the remote cauſes of gutta ſerena may be properly divided into three principal claſſes, the differences in which indicate three general methods of treatment.

This author obſerves, that the firſt claſs of cauſes ſeem to depend upon an extraordinary plethora and turgidity of the blood-veſſels of the brain, or of the optic nerves and retinæ, and a conſequent preſſure upon theſe parts. In ſuch ſtate, the functions of the retina and optic nerves muſt be obſtructed, and the important indication is to leſſen the quantity of blood ſent into the veſſels of the head. A great degree of plethora, eſpecially when the patient heats himſelf, or lets his head hang down, will frequently excite the appearance of black ſpecks before the eyes, and ſometimes complete blindneſs. A plethoric perſon, ſays Richter, who held his breath, and looked at a white wall, was conſcious of diſcerning a kind of network, which alternately appeared and diſappeared with each pulſation of the arteries. This probably originated from the plethoric ſtate of the veſſels of the retina. Boerhaave mentions a man who always loſt his ſight on getting tipſy, and regained it again on becoming ſober.

Richter thinks it likely, that it is in this manner that the diſeaſe is produced, by the ſuppreſſion of ſome habitual diſcharge of blood, by not being bled according to cuſtom, by the ſtoppage of the menſes, and by the ceſſation of hemorrhage from piles, circumſtances which frequently give birth to the gutta ſerena, if we can give credit to all the accounts of Schmucker, Scarpa, Richter, and other experienced writers on the ſubject. In the ſame manner, the complaint may be brought on by great bodily exertions, which in all probability determine a larger current of blood into the head. Richter informs us of a man who became all on a ſudden blind, while carrying a heavy burden up ſtairs. He tells us of another man, who laboured exceſſively hard for three days in ſucceſſion, exerting his ſtrength very much, and who became quite blind at the end of the third day. Pregnant women in like manner are ſometimes blind during the time of labour. Schmucker has recorded a remarkable inſtance of this in a ſtrong young woman, thirty years old, and of a full habit. Whenever ſhe was pregnant, ſhe was troubled with violent ſickneſs till the time of delivery, ſo that nothing would ſtay on her ſtomach. She was bled three or four times without effect. Towards the ninth month her ſight grew weak, and for the laſt eight or ten days ſhe was quite blind. The pupil of the eye was greatly enlarged, but retained its ſhining black appearance. She recovered her ſight immediately after delivery, and did not ſuffer any particular debility. Schmucker aſſures us, that he has been three times a witneſs of this extraordinary circumſtance. Richter ſpeaks of a perſon who loſt his ſight during a violent fit of vomiting. Schmucker acquaints us, that it is not uncommon for ſoldiers, who are performing forced marches in hot weather, to become blind all on a ſudden. All great exertions of ſtrength, when the perſon is plethoric or heated, the body bent forwards, and the head in a low poſture, are uſually attended with ſome danger of amauroſis.

The blindneſs which follows external injuries of the head, particularly violent concuſſions, may probably belong to the preceding claſs of caſes. A man, ſays Richter, who received a forcible box on the ear loſt his ſight on the ſpot. This writer conceives it probable, that the concuſſion may ſometimes produce an atony of the blood-veſſels, ſo that theſe conſequently become dilated and make preſſure upon the adjacent nerves. He ſuſpects that the gutta ſerena, which originates

during

during a violent ophthalmy, or during a ſevere inflammatory fever, may be of the ſame nature. He thinks it probable that perſons who become blind, while expoſing themſelves to the burning ſun with their heads uncovered, have their ſight impaired in a ſimilar way.

The diagnoſis of this firſt ſpecies of the gutta ſerena is founded on an acquaintance with the preceding remote cauſes, which are for the moſt part very evident, as the blindneſs, which is the conſequence of them, follows with remarkable quickneſs.

The ſecond claſs of cauſes, ſays Richter, operate by weakening either the whole body or the eye alone, and they indicate the general or topical uſe of tonic remedies. In the firſt caſe, the gutta ſerena appears as a ſymptom of conſiderable univerſal debility of the whole ſyſtem; in the ſecond caſe, the diſeaſe is altogether local. Every great general weakneſs of the body, let it proceed from any cauſe whatſoever, may be followed by a loſs of ſight. The gutta ſerena, if we can credit what Richter ſtates, has ſometimes been the conſequence of a tedious diarrhœa, ſometimes of a violent cholera morbus, ſometimes of great loſs of blood, and in other inſtances of an immoderate ſalivation. He informs us of a dropſical woman, who became blind on the water being ſuddenly let out of her abdomen. According to the ſame author, no general weakening cauſes operate upon the eyes and occaſion total blindneſs, ſo powerfully and often, as premature and exceſſive indulgence in venereal pleaſures.

The cauſes of local weakneſs in the eyes are various. Nothing tends to debilitate the eyes more, than keeping them fixed very attentively for a long while upon minute objects. However long and attentively objects may be looked at, the eye does not ſuffer nearly ſo much, if the objects are at all diverſified. A frequent change in ſuch things as are looked at ſtrengthens and refreſhes the eye. The ſight becomes ſtill more impaired by looking at objects with only one eye, as is done with teleſcopes and magnifying glaſſes; for when one eye remains ſhut, the pupil of that which is open always becomes dilated beyond its natural diameter, and lets an extraordinary quantity of light into the organ. The eye is generally very much hurt by being employed in the cloſe inſpection of brilliant, light-coloured, ſhining objects. They are greatly miſtaken, ſays Richter, who think that they ſave their eyes, when they illuminate the object which they wiſh to ſee in the evening with more lights, or with a lamp which intercepts and collects all the rays of light, and reflects them on the body which is to be looked at. Richter makes mention of a man, who, in the middle of winter, went a journey on horſeback through a ſnowy country, while the ſun was ſhining quite bright. He ſpeaks of another perſon who loſt his ſight in conſequence of the chamber in which he lay being ſuddenly lighted in the night-time by a flaſh of lightning. A man was ſeized with blindneſs, while one night he was keeping his eyes fixed for ſome minutes upon the full moon, in a fit of contemplation. In Richter's opinion the concuſſion of the head from external violence may ſometimes in all probability operate directly upon the nerves, ſo as to weaken and render them completely paralytic.

The third claſs of cauſes conſiſt of irritations, which in ſome inexplicable way, directly, or probably, for the moſt part directly, affect the optic nerves ſo as to make them inſenſible of the impreſſion of light. The greater part of ſuch irritations lies in the abdominal viſcera, whence they ſympathetically operate upon the eyes. It is indiſputably true that the kind of amauroſis which is moſt common depends upon ſome irritation in the gaſtric organs. It will often be learnt that patients of this kind have had a great deal of trouble, long griefs, and repeated cauſes of vexation, anger, and other paſſions, which are ſuppoſed to diſorder the bilious ſecretion, and bring on a wrong ſtate of the fluids in the alimentary canal. Richter tells us of a man, who loſt his ſight a few hours after being in a violent paſſion, and recovered it again the next day, upon taking an emetic, by which a conſiderable quantity of bile was evacuated. A woman was known to become blind, whenever ſhe was troubled with acidities in the ſtomach. (Anfangſgr. der Wundarzn).

The continental ſurgeons are exceſſively comprehenſive in their ideas of the cauſes of the gutta ſerena, and with many truths, they blend an evident quantity of uneſtabliſhed conjectures, and palpable abſurdities. It would be idle credulity indeed, to put faith in the aſſertions of this diſeaſe being occaſioned by the bad treatment of particular fevers, ſuppreſſed diarrhœas, the repelling of eruptive complaints, &c. Worms are alſo alleged to be ſometimes the cauſe of amauroſis, and this ſtatement may poſſibly be correct. The intermitting or periodical gutta ſerena is ſaid to depend in general upon ſome diſorder in the gaſtric organs.

Beſides theſe irritations in the chylopoietic viſcera, there are many others, which are repreſented as occaſionally affecting the eyes, and producing blindneſs. From moſt of theſe latter cauſes we ſhall withhold our belief, notwithſtanding they are ſupported by the high united authorities of Schmucker, Richter, and Scarpa. In a work like the preſent, however, it might not be altogether right to paſs over in ſilence any important opinions of theſe eminent ſurgeons, in relation to the cauſes of amauroſis. What will the Engliſh practitioner think, when he reads that *arthritic* or *gouty matter* is one of the moſt remarkable irritations which are productive of the gutta ſerena? What will be his ſentiments when he is told, that this ſerious blindneſs ſometimes originates from the repulſion of the gout or rheumatiſm, from a badly treated itch, and from repelling a tinea capitis? Can he ſenſibly believe, that a lady could really have a gutta ſerena brought on by merely going to cool herſelf in her garden, while heated with dancing? Ought he to credit, that what is called the *imprudent drying up* of an old ulcer will ſometimes occaſion a gutta ſerena? Ought he to believe, that the ſtoppage of a fluor albus will? Can he be made to ſuppoſe, that the matter of lues venerea is a frequent cauſe of amaurоſis? Will he imagine with Richter, that the gutta ſerena, which ſometimes comes on at the termination of acute fevers, is likely to be the effect of the critical matter? For our own part with all the reſpect which we can ſummon for the moſt experienced ſurgeons of the continent, we cannot look upon the preceding aſſertions as any thing elſe than groſs errors, ariſing from the unexploded ſtate of the humoral pathology in foreign countries.

A violent fright, which is conſidered as being a frequent cauſe of the gutta ſerena, is ſuppoſed by Richter to operate chiefly by irritating the nerves.

The blindneſs ſometimes proceeds from a mechanical kind of irritation. A man received in his right eye a ſmall ſhot, which pierced the upper eyelid, and lodged at the upper part of the orbit, between the eye-lid and eye-ball, ſo that it could be externally felt. Richter adds that he ſhortly afterwards became blind in the left eye, but recovered his ſight in it again upon the exciſion of the ſhot.

Sometimes, ſays this experienced ſurgeon, the irritation, exciting amauroſis, ſeems to have its ſeat in the mucous membrane of the noſe and frontal ſinuſes. He fancies, that there is ſome ground for believing, that the ſtoppage of a catarrhal running from the noſe may ſometimes actually occaſion

caſion a gutta ſerena. However this may be, he ſtates it as certain, that ſuch patients frequently complain of a great dryneſs of the noſe, and that the coming on of a ſpontaneous or excited diſcharge from the noſtrils has been known to effect conſiderable benefit. Such patients alſo frequently experience many diſagreeable ſenſations about the frontal ſinuſes, a heavineſs, ſhootings, contractions, &c. The fact of wounds of the eye-brow being often followed by a gutta ſerena, proves that the cauſe of this diſeaſe is not ſituated far from thoſe bony cavities. However, the reader ought to be appriſed that it is chiefly ſuch wounds as intereſt the ſupra-orbitary nerve, which are commonly ſuppoſed to be apt to bring on amauroſis.

The gutta ſerena is generally difficult of cure. However, the degree of difficulty in relieving the diſeaſe varies in different caſes, according to the way in which the malady originates, and the nature of its cauſe.

We ſhall extract the following prognoſis, relative to the gutta ſerena, from Scarpa's excellent work on the diſeaſes of the eye. "The *perfect inveterate amauroſis*, with organic injury of the ſubſtance, conſtituting the immediate organ of viſion, is a diſeaſe abſolutely incurable. The *imperfect recent amauroſis*, particularly that which is *periodical*, generally admits of a cure, ſince it is moſt frequently connected with a diſordered ſtate of the ſtomach and primæ viæ, or is dependent on cauſes which, though they affect the immediate organ of viſion, may be removed without leaving any trace of diſorganization, either in the optic nerve or retina.

"In general, thoſe caſes of amauroſis may be regarded as incurable, which have exiſted for ſeveral years in perſons advanced in age, and whoſe ſight has been weak from their youth; which have been ſlowly formed, at firſt with a morbid increaſe of ſenſibility in the immediate organ of viſion, and afterwards with a gradual diminution of perception in this organ to complete blindneſs; in which the pupil is immoveable, without being much dilated, but where it has loſt its circular figure, or when it is ſo much dilated as to appear as if the iris were wanting, having alſo an unequal or fringe-like margin; in which the bottom of the eye, independently of opacity of the cryſtalline lens, has an unuſual paleneſs, ſimilar to horn, ſometimes inclining to green, reflected from the retina as if from a mirror; which are accompanied with pain of the whole head, and with a conſtant ſenſe of tenſion in the eye-ball; which have been preceded by great and protracted excitement of the whole nervous ſyſtem, and afterwards by general debility and languor of the whole conſtitution, as after the long abuſe of ſpirituous liquors, manuſtupration, or premature venery; which have been preceded or accompanied by attacks of epilepſy, or by frequent and violent hemicrania; which have come on in conſequence of violent and obſtinate internal ophthalmia, at firſt with an increaſed, but afterwards diminiſhed ſenſibility of the retina, and flowneſs of motion in the pupil; which, beſides being inveterate, are the conſequence of blows upon the head; which have been occaſioned by direct blows upon the eye-ball; which have appeared after a violent contuſion and laceration of the ſupra-orbital nerve, whether the diſeaſe has taken place immediately after the blow, or ſome weeks after the healing of the wound of the ſupercilium; which have been occaſioned by extraneous bodies penetrating the eye-ball, as leaden ſhot, &c.; which are derived from a confirmed lues venerea, in which the preſence of one or more exoſtoſes upon the forehead, upon the ſides of the noſe, or upon the maxillary bone, lead to the ſuſpicion, that there may be alſo ſimilar exoſtoſes within the orbit. Laſtly, thoſe are incurable, which are conjoined with a manifeſt change of figure and dimenſion of the whole eye-ball, as when it is of a long oval figure, or of a preternatural bulk or ſmallneſs.

"On the contrary, thoſe caſes of *recent imperfect amauroſis* moſt frequently at leaſt, if not always, admit of a cure, which, although the patient be almoſt or even completely deprived of ſight, have not been produced by any of thoſe cauſes, which are capable of contuſing or deſtroying the organic texture of the optic nerve or retina; in which the immediate organ of viſion preſerves ſome, though little, ſenſibility to the light, whether in the direction of the axis of viſion, or laterally; in which the amauroſis being ſudden and recent, the pupil, although preternaturally dilated, is not exceſſively ſo, and is regular in its circumference; behind which, the bottom of the eye is of a deep black colour, as in a natural ſtate, which have not been preceded or accompanied by violent and continual pain in the head and eye-brow, nor by a ſenſe of conſtriction in the eye-ball; which have originated from violent anger, exceſſive grief, or terror; which have ſucceeded an exceſſive fulneſs and crudity of the ſtomach, plethora, either general, or confined to the head, the ſuppreſſion of accuſtomed ſanguineous diſcharges from the noſe, uterus, or hemorrhoids; which are occaſioned (as Scarpa unwarrantably ſuppoſes) by an evident metaſtaſis of variolous, herpetic, or gouty matter; which are the conſequence of profuſe loſs of blood; which are to be referred to a nervous debility, not inveterate in perſons who are young, and which is conſequently yet ſuſceptible of being remedied; which are produced by convulſions and violent efforts during a laborious parturition; which accompany the courſe or decline of acute or intermittent fevers; laſtly, which are periodical, or which come on and diſappear at intervals, every day, every three days, every month, or at a certain ſeaſon of the year."

Before entering into the conſideration of the treatment of the gutta ſerena, we are deſirous of noticing a few remarkable circumſtances, which are connected with the diſeaſe. It ſometimes happens that when a patient ſhuts one eye, he can only half diſtinguiſh objects, but that if he opens both eyes, he ſees every thing in its natural form. In this caſe, according to Schmucker, one eye is ſound, and only ſome fibres of the nerve of ſight are injured in the other. It alſo ſometimes happens, that in the gutta ſerena, which comes on gradually, the patient ſees double with both eyes. Some years ago Schmucker cured a major of huſſars, who ſaw the three lines of his ſquadron double, and the ſame ſurgeon was ordered by the king of Pruſſia to attend a gentleman who was afflicted in a ſimilar way. Such caſes are, in the opinion of the foregoing writer, brought on by a violent diſtention of the veſſels of the choroides, where he thinks that varices may eaſily ariſe, in conſequence of the weak reſiſtance of that membrane. In this manner the filaments of the retina ſuffer preſſure, and the rays of light are broken. Under theſe circumſtances, if prompt aſſiſtance be not afforded, total, and frequently incurable blindneſs may be the conſequence. Schmucker met with an example of this (the only one in his practice) in a young man 26 years of age. When he applied to this eminent ſurgeon, he had been blind a year. Before he became blind he remarked, that, after any violent emotion, his ſight at firſt was weak, and that objects were afterwards ſeen double. When his circulation was at all hurried, he ſaw black ſpots before his eyes, and at length was quite blind. The veſſels of the choroides were as large as if they had been injected with wax, and every kind of ſurgical aſſiſtance proved ineffectual.

In the perfect gutta ſerena, the pupil of the eye is generally deſtitute of motion. This ſymptom, however, as we have already ſtated, is not invariably attendant on the diſor-

der. Janin and Richter have ſeen the pupil capable of motion in caſes of amauroſis; Schmucker has twice ſeen the ſame circumſtance; and we have obſerved it in not leſs than eight inſtances, ſome of which were in St. Bartholomew's hoſpital, and others in the York hoſpital, Chelſea. The reaſon of this occurrence is thus explained by ſurgical authors: the iris, which forms the pupil, is a continuation of the choroides; the various nervous filaments, which are diſtributed to the iris, and endue it with ſenſibility and a power of motion, ariſe from the lenticular ganglion, which is formed by the third and fifth pairs. As all theſe nerves have no connection with the nerves of ſight, it is poſſible for them to retain their ſenſibility, while the latter are quite devoid of that property.

The preceding kind of caſe is ſometimes reverſed; namely, the nerves of the iris may be paralytic, while thoſe of ſight continue unimpaired. Schmucker informs us that he was acquainted with a woman whoſe pupil was uncommonly diſtended, and totally incapable of motion. Her ſight was very weak, and ſpectacles were of no uſe to her. She could ſcarcely diſcern any thing by day, or in a ſtrong light; but ſhe could ſee rather better at night and in the dark. This infirmity of ſight depended upon the dilated paralytic ſtate of the pupil, by which too many rays of light were admitted into the eye; and the reaſon why the patient could ſee better at night, was becauſe the pupil, in its natural ſtate, always becomes widened and dilated in a dark ſituation. See Vermiſchte Chirurgiſche Schriften Von J. L. Schmucker.

In the treatment of the gutta ſerena, the practitioner ought firſt to endeavour to diſcover and remove the cauſe of the diſeaſe. This is the ſureſt and beſt way of proceeding; but it is worthy of notice that ſight does not invariably return, although the real cauſe of the blindneſs is radically removed. In ſuch caſes, the continuation of the loſs of ſight is aſcribed to the torpor of the nerves, which have been for a conſiderable time without action, and have been impaired by the diſeaſe. The practitioner uſually preſcribes ſtimulants and tonics, with a view of bringing the nerves into their original ſtate of activity. In other caſes ſight returns as ſoon as the cauſe of the diſeaſe is removed. When it is found impoſſible to make out any thing reſpecting the cauſe of the diſorder, the ſurgeon ſhould found the curative indications upon the ſymptoms and appearances which have taken place in the origin and courſe of the diſeaſe, and from which ſome conjectures may be drawn reſpecting the nature of the caſe. When no appearances of this kind occur, and nothing can be learnt about the cauſe of the malady, the ſurgeon muſt have recourſe to ſuch empirical remedies as extenſive experience has ſhewn to be ſometimes truly capable of removing the affection, although an explanation cannot always be given of the manner in which they operate.

We ſhall follow Richter, and firſt treat of that method of cure which is directed againſt the cauſes of the diſeaſe, and which is to be regarded as the moſt proper whenever circumſtances will admit of its adoption. In that ſpecies of amauroſis, which ariſes from the firſt claſs of cauſes, namely, from thoſe which ſeem to induce the diſeaſe, by means of a preternatural fulneſs and dilatation of the blood-veſſels of the brain or eye, the indication is evidently to leſſen the quantity of blood, and divert this fluid from the head. For this purpoſe the patient may be bled in the arm, temporal artery, or foot. This evacuation is to be repeated as often as ſeems neceſſary, and it will be better to begin with taking away from twelve to ſixteen ounces. It is alſo adviſed by Schmucker to apply ten or twelve leeches to the neck and temples. The efficacy of bleeding in the cure of particular caſes of the gutta ſerena is ſtrikingly exemplified by numerous well authenticated obſervations; and a ſingle evacuation of this kind has been known to ſuffice for the reſtoration of ſight. Richter informs us of a woman, who had left off having children, who loſt her ſight, and recovered it again by being only once bled in the foot. A ſpontaneous hemorrhage from the noſe alſo cured a young man who had been blind for ſome weeks.

General bleeding ſometimes proves ineffectual, unleſs aſſiſted by topical. Leeches may be applied to the temples, or cupping-glaſſes to the back part of the neck. When the diſorder ſeems to be connected with an interruption of the menſes, or the ceſſation of bleeding from piles, leeches may be put on the perinæum, the inſide of the thigh, or the ſacrum. Local bleeding, however, ſeldom avails, except the whole maſs of blood has been previouſly diminiſhed by a prudent employment of the lancet. Beſides bleeding, the ſurgeon may advantageouſly have recourſe to other means, emollient glyſters, purgatives, bliſters on the lower extremities, bathing the feet in warm water, &c.

In ſome caſes all the foregoing means fail in producing the deſired benefit, even when they have been followed up as far as the pulſe and ſtrength of the conſtitution will allow. Here the diſorder may be of two kinds. It may either depend upon the ſtoppage of ſome wonted evacuation of blood, or elſe upon ſome other cauſe of the firſt claſs. In the firſt of theſe caſes, ſays Richter, experience ſhews that the diſeaſe will ſometimes not give way before the accuſtomed diſcharge is re-eſtabliſhed on which the malady depends; notwithſtanding evacuants may be employed in any way whatſoever. A woman (as this author acquaints us) who had loſt her ſight in conſequence of a ſudden ſuppreſſion of the menſes, could not recover it again till three months after the return of the menſtrual diſcharge, notwithſtanding every ſort of evacuation was tried. He alſo tells us of another woman who had been blind half a year, and did not menſtruate, and to whoſe external parts of generation leeches were ſeveral times applied. As often as the leeches were put on, ſays Richter, the menſes in part recommenced; and as long as they made their appearance, which was ſeldom above two hours, the woman always enjoyed a degree of viſion.

In the ſecond ſort of caſe, to which we have alluded above, or that in which the diſeaſe has not its origin from a ſtoppage of any natural or habitual diſcharge of blood, and does not yield to the evacuating plan, Richter thinks that the ſurgeon is juſtified in concluding that the preternaturally dilated veſſels have loſt their tone and proper diameter, and in employing topical corroborating remedies, particularly cold water. That the veſſels do ſometimes remain in this weakened ſtate, ſo as to protract the diſeaſe, the preceding author endeavours to ſhew, by the caſe of a woman who loſt her ſight in conſequence of the ſtoppage of the menſes; and though, on the return of this diſcharge, ſhe recovered it again, yet ſhe was afterwards in the habit of loſing it again, for the ſpace of two days, before the beginning of every menſtruation, and of regaining it as ſoon as this evacuation began. Waſhing and bathing the whole head with cold water, eſpecially the part about the eyes, may often be practiſed in theſe caſes with ſingular benefit after free evacuations.

When the return of ſight cannot be brought about in this manner, the ſurgeon may put in practice ſuch means as ſeem calculated to ſtimulate the nerves, and remove the torpid affection of the optic nerves in particular. Of the latter remedies, Richter ſays emetics are the principal. Soldiers, who loſe their ſight in performing forced marches in hot

weather, very commonly have it re-eſtabliſhed again by being immediately bled, and taking an emetic the next day. (See Schmucker's Chir. Wahrnehmungen, 1 Theil.) Paralytic affections, remaining after injuries of the head, may ſometimes be cured by making an iſſue upon the mamillary future. (See Bromfield's Churirg. Obſervations, vol. i.) Perhaps, obſerves Richter, this plan might be of ſervice in the gutta ſerena, which is conſequent to injuries of the head and concuſſions of the brain.

The treatment of that ſpecies of the gutta ſerena, which is regarded as the effect of ſome unnatural irritation, requires the inveſtigation and removal of ſuch irritation. When this cannot be diſcovered, Richter adviſes the employment of remedies which leſſen the ſenſibility of the nerves, and conſequently render them leſs apt to be affected by the irritation of whatever ſort it may be. Sometimes the irritation is both diſcoverable and removeable, and ſtill the effect, that is, the blindneſs, continues. In this circumſtance, the ſurgeon muſt endeavour to obviate the impreſſion which the irritation has left on the nerves by the uſe of anodynes, or elſe he ſhould try to remove the torpor of the nerves by the employment of ſtimulants. In moſt caſes, according to Richter, Schmucker, and Scarpa, the irritation, which is productive of the diſeaſe, is ſituated in the abdominal viſcera. Sometimes, ſays the firſt of theſe eminent continental ſurgeons, it is plainly of a bilious nature, and demands the exhibitions of purgatives and emetics. He informs us of a man who became blind after a ſevere bilious colic, but was cured by merely taking an emetic and a purge. Another perſon alſo, who loſt his ſight in conſequence of meeting with ſome conſiderable vexation, recovered it by only taking one emetic.

Scarpa, the celebrated anatomiſt and ſurgeon at Pavia, has lately publiſhed, in his excellent work upon the diſeaſes of the eye, a very intereſting relation of the kind of treatment, which is found upon the continent to be attended with uncommon ſucceſs in the caſes of gutta-ſerena, connected with ſome diſorder in the gaſtric ſyſtem. "It is found," ſays he, "from the careful obſervations of Schmucker and Richter, that this diſeaſe is moſt frequently derived from a morbid excitement or irritation in the digeſtive organs, either alone, or accompanied with general nervous debility, in which the eyes participate ſympathetically. According to theſe principles, in the greater number of caſes of *recent imperfect amauroſis*, the principal indication of cure, which the ſurgeon ought to fulfil in the treatment of this diſeaſe, is that of unloading the ſtomach and primæ viæ of the faburræ and morbific ſtimuli; and afterwards of ſtrengthening the gaſtric ſyſtem, facilitating the digeſtion, and, at the ſame time, exciting the whole nervous ſyſtem, and particularly that of the eyes, which are affected and rendered torpid by a ſympathetic connection.

"With reſpect to the firſt part of the treatment of the *imperfect amauroſis*, the intention is perfectly anſwered by emetics and internal reſolvents. In the claſs of emetics, experience has taught that the antimonium tartarizatum is preferable to every other; and that when given afterwards, in ſmall and divided doſes, it anſwers the purpoſe of a reſolvent medicine, the action of which may be increaſed by conjoining it with gummy or ſaponaceous ſubſtances. In the treatment of the imperfect amauroſis, therefore, which is moſt frequently ſympathetic, and depending on acrid matters in the primæ viæ, it will be proper at firſt, in the greater number of caſes, to diſſolve, for an adult, three grains of tartarized antimony in four ounces of water, of which two table-ſpoonfuls may be taken every half hour, until it produces naufea, and afterwards abundant vomiting. On the following day he ſhould be ordered to take the reſolvent powders, compoſed of one ounce of the cryſtals of tartar and one grain of the tartarized antimony, divided into ſix equal parts, of which the patient ſhould take one in the morning, another four hours afterwards, and the third in the evening, during eight or ten ſucceſſive days. This medicine will produce a ſlight naufea, and ſome evacuations of the bowels more than uſual; and perhaps, after ſome days, even vomiting. But if, during the uſe of this opening powder, the patient makes ineffectual efforts to vomit, and complains of a bitter taſte and want of appetite, without any amendment of the ſight, the emetic ſhould be repeated, and even a third and fourth time, if the preſence of the morbific ſtimuli in the ſtomach, bitter taſte, tenſion of the hypochondria, and eructations and tendency to vomit, require it; for it not unfrequently happens that the patient, on the firſt evomition, throws up only matter, with a little mucus; but, on repeating the emetic, after the naufeating powder has been uſed for ſome days, a conſiderable quantity of yellowiſh green matter will be thrown up, which will greatly relieve the ſtomach, head, and eyes.

"The ſtomach being cleared, the opening pills of Schmucker ſhould be preſcribed, or thoſe of Richter. (The firſt are compounded as follows: ℞ Gum-ſagapen. Galban. Sap. Venet. an. drachmam unam, Rhei opt. drachmam unam et ſemis. Antimonii tartarizati grana ſexdecim, Suc. liquirit. drachmam unam. F. pilulæ gran. unius. Schmucker makes his patients take fifteen of theſe pills, morning and evening, for the ſpace of four or even ſix weeks. Richter's pills are thus made: ℞ Gumm. Ammoniac. Aſſ. fœtid. Sap. Venet. Rad. Valerian. ſ. p. Summit. Arnicæ an. drachmas duas. Antim. tartariz. grana octodecim. F. pilulæ granorum duorum. On the continent fifteen are preſcribed thrice a day; but in this country it would be better to make the pills larger, and direct a ſmaller number to be taken at a time.) The phenomena, which are uſually obſerved to happen, in conſequence of this treatment, are the following: the patient, after having vomited copiouſly, feels more eaſy and comfortable than before. Sometimes, on the ſame day on which he has taken the emetic, he begins to diſtinguiſh the ſurrounding objects; at other times this advantage is not obtained till the fifth, the ſeventh, or tenth day; and in ſome caſes, not till ſome weeks after the exhibition of the emetic, and the uninterrupted uſe of the opening powders or pills. As ſoon as the patient begins to recover his ſight the pupil is found leſs dilated than before, and is alſo more contracted, when expoſed to the vivid light of a candle; and in proportion as the power of viſion augments, this contraction and mobility of the pupil increaſe. Upon the whole, the cure is ſeldom completed in leſs than a month, during which time the uſe of local remedies, calculated to excite the languid action of the nerves of the eye, ſhould not be neglected, as will be hereafter mentioned.

"When the ſurgeon ſhall have ſufficient reaſon to believe that, by means of theſe remedies, the offending matters which ſtimulated the ſtomach, have been perfectly eliminated, and eſpecially after the patient has in a great meaſure regained his ſight, the plan of treatment ſhould be directed to ſtrengthen the ſtomach and invigorate the nervous ſyſtem in general, and that of the nerves of the eye in particular. He ſhould, therefore, preſcribe a powder, compoſed of one ounce of the cinchona, and half an ounce of valerian root, divided into ſix equal parts, of which the convaleſcent ſhould take one in the morning, and another at night, in any convenient vehicle, and ſhould continue the uſe of this medicine for at leaſt five weeks. In the mean time he ſhould live on tender ſucculent food and cooling broths, ſhould take a

moderate quantity of wine, and uſe gentle exerciſe in a ſalubrious air.

" As a local application, both during the continuance and decline of the imperfect amauroſis, in order to rouſe the languid action of the nerves of the eye, the vapour of the aqua ammoniæ puræ, properly applied to the affected eye, is of the higheſt advantage. This remedy is employed by placing a ſmall veſſel containing it near the patient's eye, ſo that the very penetrating vapour, with which it is ſurrounded, may excite a pricking ſenſation in that organ; by the action of which, in leſs than half an hour, the eye, which is expoſed to it, becomes red and waters copiouſly. It is then proper to deſiſt from it, and repeat it three or four hours afterwards, and continue it in this manner, until the amauroſis is perfectly cured. If both the eyes are affected with this diſeaſe it is unneceſſary to obſerve, that it is requiſite to have two ſmall veſſels filled with the aqua ammoniæ puræ, or if one only be employed, that it will be neceſſary to hold it firſt to one eye and then to the other, until both water abundantly and become red. It is neceſſary to renew the aqua ammoniæ puræ every third day, in order to preſerve its activity. This very uſeful application ought to be employed from the commencement of the treatment of the imperfect amauroſis, or, at leaſt, immediately after the patient's ſtomach has been unloaded of the offending matter, by means of an emetic, and continued for a length of time, even after the amauroſis is diſſipated. Thilen (Med. und Chirurgiſche Bemerkungen, § Amauroſis,) beſides many others, aſſures us, that he has alſo uſed this local remedy in ſuch caſes with advantage. The action of the vapour of the cauſtic volatile alkali, applied to the eyes affected with incomplete amauroſis, may be alſo aſſiſted by other external ſtimuli, applied to parts of the body, which have a cloſe conſent with the eyes, as bliſters to the neck, friction upon the eye-brow with the anodyne liquor, and irritation of the nerves of the internal noſtrils by means of ſternutatory powders, as that compoſed of two grains of the hydrargyrus vitriolatus, and a ſcruple of the powder of the leaves of betony; and laſtly, the electric fluid. Electricity has been propoſed as one of the principal means of curing the amauroſis; but experience has ſhewn, that no confidence is to be placed in it, except as a ſecondary remedy; and Mr. Hey (Med. Obſerv. and Enquiries, vol. v. p. 26.), one of the moſt zealous promoters of this practice confeſſes, that electricity is only uſeful in caſes of recent amauroſis; and moſt frequently only when combined with appropriate internal remedies, among which reſolvents are the principal. Scarpa on the eyes, tranſl. by Briggs.

Beſides the remedies above-mentioned, ſeveral other medicines have obtained repute for their efficacy in the caſes of gutta ſerena, proceeding from ſomething wrong in the abdominal viſcera. We ſhall juſt enumerate a few of the principal: half a dram of kali tartarizatum, from four to ſix times every day, with from eight to fifteen grains of caſtor; a grain of the antimonial powder, from four to eight times a day, either alone, or conjoined with the kali tartarizatum and bitter reſolvent extracts; a ſolution of from one to two grains of antimonium tartarizatum in an ounce and a half of aqua ammoniæ acetatæ, two drams of ox's gall, and three ounces of water, of which mixture the patient is to take two table-ſpoonfuls from four to ſix times a day; five grains of belladonna once or twice a day; a ſolution of black hellebore in antimonial wine, of which medicine the patient is to take a ſufficient quantity to procure a couple of gentle evacuations from the bowels every day; a thin electuary, compoſed of from one to two drams of the powder of hemlock, and four ounces of honey, which quantity the patient is to take gradually in the courſe of four and twenty hours; a powder made of one grain of calomel, one grain of the ſulphur auratum antimonii, and eight of hemlock, which is to be taken at night, or every evening and morning.

Some of the preceding reſolvent remedies have a warm heating effect, while the other are of a cooling, lowering nature. The laſt are ſerviceable to ſuch patients as are ſubject to fluſhes of heat, and have a ſmall irritable pulſe, while the firſt are principally calculated for patients, who have a ſmall, ſoft, ſlow pulſe, and are not of irritable habits. However, as Richter further informs us, we cannot always foretel with certainty what kind of reſolvent medicine will anſwer in every particular caſe. Comparative trials with different remedies will, in general, ſoon point out the one which is the beſt. During the employment of ſuch medicines as the foregoing, emetics and purgatives are to be adminiſtered as often as occaſion requires. At length, tonic nervous medicines become neceſſary. Richter, in confirmation of the propriety of the preceding plan, cites the caſe of a man, two and twenty years of age, who had been blind three years, but was entirely cured in the courſe of eight weeks, by the alternate uſe of emetics and doſes of the kali tartarizatum. In this ſpace of time he took twelve vomits. Whenever he had taken the kali tartarizatum for four or ſix days in ſucceſſion, he was affected with giddineſs, loſs of appetite, a furred tongue, oppreſſions, &c. An emetic not only always removed theſe ſymptoms, but improved the ſight ſo much, that viſion was perfectly re-eſtabliſhed after the twelfth vomit.

According to ſurgical writers, worms are frequently a cauſe of the gutta ſerena, particularly in children. Perſeverance in the uſe of calomel, ſemen ſantonicum, rhubarb, or jalap, and laſtly, of valerian, will generally effect an entire cure of this ſpecies of blindneſs. Richter, and other continental ſurgeons, alſo comprehend among the cauſes of amauroſis the repulſion of eruptive complaints, the healing of old ulcers, and the ſtoppage of aqueous, or mucous diſcharges. The chief remedies recommended in theſe caſes are from ſix grains to a ſcruple of the ammonia præparata; a mixture of the ſpiritus ammoniæ ſuccinatus, and antimonial wine; bathing, eſpecially in ſulphur waters; the ſolanum lignoſum, or dulcamara, either alone, or conjoined with antimonial wine; emetic tartar adminiſtered in ſmall doſes ſo as only to excite nauſea, and occaſionally in larger ones, for the purpoſe of bringing on vomiting; the extractum aconiti with antimonial wine; the tinctura thebaica, and antimonial wine in equal parts; ſulphur; iſſues; and electricity. It is plain that ſeveral of theſe remedies are dictated by the idea of ſome particular kind of morbid matter being driven inward into the blood, according to the exploded notions of the old humoral pathology. We fear, that the continental ſurgeons here give their advice more from hypotheſis than experience. However, if the medicines are productive of the benefit imputed to them, we will not argue about the principle of their operation, or whether the repulſion of a ſcald head, or other eruptive diſeaſe, can bring on the gutta ſerena. Richter adduces the following example in illuſtration of the foundneſs of his practice. A boy, twelve years old, who had entirely loſt his ſight, in conſequence of the drying up of a tinea capitis, was completely cured by uſing the enſuing ointment: R Flor. Sulph. Vitriol. Alb. Pulv. baccar. laur. āā Olei Olivæ q. s. ad linimentum. Some of this application (ſays Richter) was rubbed, every morning and evening, upon the elbow joints; in three weeks the tinea capitis re-appeared; and from that moment the ſight began to return.

GUTTA SERENA.

Foreign ſurgeons make mention of an amauroſis, which proceeds from a venereal cauſe, and demands the employment of mercury. This caſe, they ſay, is ſometimes incurable, and perhaps may depend upon an exoſtoſis, ſituated in the orbit, and making preſſure upon the optic nerve.

The gutta ſerena, by many writers alleged to originate from the ſudden check of gouty complaints, requires, ſays Richter, either that the gouty matter ſhould be expelled from the ſyſtem, or brought back to the place from which it has been driven. This author informs us, that a man who had applied cold water to his gouty foot became blind, and the pain of the diſeaſe ſubſiding, and upon the recurrence of this ſymptom, the next day, the power of ſeeing returned. A gutta ſerena, brought on by what Richter ſuppoſes was a metaſtaſis of a fever, Schmucker cured by ſome pills containing emetic tartar. (See Vermiſchte Schriften, 2 Band.) In another ſimilar caſe, reported in the Memoirs of the Swediſh Academy of Sciences, a ſeton in the neck was found of ſervice. A woman, who had loſt her ſight in conſequence of a violent fright, is ſaid by Richter to have been cured by taking valerian, after ſome mildly purging medicines. He ſtates that, in another caſe of this kind, cajeput oleum was found of uſe, after a gentle evacuation. (See Anfangſgr. der Wundarzneykunſt. Band 3.)

The foreign mode of treating the gutta ſerena, connected with the gout, fevers, ſmall-pox, or meaſles, may be fully underſtood from the following caſes, and remarks afforded us by Schmucker. "You muſt endeavour (ſays he) to remove the remnants of theſe diſeaſes as quickly as poſſible, and bring the conſtitution into its proper ſtate. Emetic tartar, in the doſe of three or four grains, is at firſt an efficacious remedy, on account of its active operation. You then apply bliſters to the neck, arms, and calves of the legs. If the ſight is improved by this firſt ſtrong vomit, you repeat ſmall doſes of the emetic tartar, and immediately exhibit an infuſion of woodlice. I ſhall cite a few inſtances in confirmation of its efficacy. A man two and fifty years of age, who was ſubject to fits of the gout, about two years ago, had ſo violent an attack in the right ſhoulder, and was in ſuch extreme pain, that it not only prevented him from ſleeping for ſeveral nights, but brought on a conſiderable degree of fever. A friend adviſed him to apply to the part affected cloths dipped in cold water, and this had not been repeated above four times when the pain ceaſed, but in twelve hours the patient became blind in both eyes. I was conſulted the following day, and found the pupil greatly diſtended and immoveable, the patient being quite unconſcious of the impreſſion of light. I immediately ordered the part where the pain had been to be rubbed with bruſhes, and covered with a bliſtering plaſter, and three grains of emetic tartar to be taken, which occaſioned violent vomiting. The next day the patient aſſured me, that he had already had ſome perception of light, and I found the pupil ſomewhat moveable. The plaſter of cantharides had drawn well; I took it off, applied another, and, in order to increaſe the irritation, placed another bit lower down, about as broad as my hand. As an internal medicine, I ordered him four grains of emetic tartar in four ounces of orange water, half of which I made him take, and, when that had operated, he was directed to take a ſpoonful every hour. He vomited ſeven times in the day, and in the evening ſaw a little better, though he could not diſcern any objects diſtinctly. The emplaſtrum cantharidum was taken off, and the ſore dreſſed with the unguentum baſilicum, in which there was ſome of the powder of cantharides. On the third morning the patient could already diſtinguiſh me tolerably well. I again mixed two grains of emetic tartar with ſix ounces of water and gave him a ſpoonful every two hours. This only operated once, making him, however, very ſick. The pupil of the eye again recovered its power of motion, and began viſibly to contract. On the following day I gave him an infuſion of woodlice, with the above-mentioned reſolvent pills, and in nine weeks the patient was entirely cured. Latterly, I made him hold ſome ſtrong ſpirits in the palm of his hand, and apply the vapour to his eyes.

"A girl, ſeven years of age, caught the meaſles, and being ſuffered to run about in the cold, they were driven in, and the child became quite blind in both eyes. Several perſons were conſulted, but, notwithſtanding their efforts, ſhe continued blind. Two years afterwards I was conſulted; but as the diſeaſe had been of ſo long duration, I had little hopes of a cure. Nevertheleſs, I conſented to make the trial. I made her take, at firſt, a ſcruple of the kali tartatarizatum three times a day, obſerve a vegetable diet, and drink a decoction of graſs-root for her beverage. On the tenth day I gave her a gentle laxative, and then made her take ten of reſolvent pills. During the firſt fortnight ſhe did not experience any ſickneſs, nor did any change happen; but in the third and fourth weeks ſhe was ſick at the ſtomach, and had occaſional vomiting. In ſix weeks, the pupils of the eyes, particularly that of the right eye, had ſome motion, and the girl could diſtinguiſh day and night. I then gave her every morning forty woodlice in ſome broth, two pills every day, and made her apply ſpirituous vapours to her eye. After uſing theſe remedies ſix weeks, ſhe could diſtinctly diſcern objects, particularly with the right eye. I therefore continued this plan, and applied behind the ears plaſters of cantharides, which were kept open nineteen days. In the mean while, her ſight grew better and better; but in order to excite greater irritation, and more diſcharge, I put another larger bliſter on the neck. I afterwards made an iſſue in her left arm, ordering her to take twelve pills at bed-time, and uſe the ſpirituous vapour. In nine months ſhe got perfectly well." (See Schmucker's Vermiſchte Chirurgiſche Schriften).

With regard to the gutta ſerena, ariſing from wounds of the eye-brow, Richter thinks it improbable that the diſeaſe can proceed from an actual injury of the ſupra-orbitary nerve; for it ſeldom follows the wound immediately, but moſtly at a late period, when the part is either nearly or entirely healed. The kind of wound, alſo, which induces the loſs of ſight, is not always preciſely in the ſituation of the nerve. The nerve has ſometimes been purpoſely divided, without being followed by blindneſs, and, occaſionally, this ſpecies of amauroſis has been cured, which could hardly have happened, if the diſorder had actually depended upon a wound of the nerve.

In the opinion of this author, it appears likely, that the proximate cauſe of the gutta ſerena, in this inſtance, is to be imputed to the cicatrix, by which the nerve is preſſed and irritated, as the loſs of ſight in general does not take place till the ſcar begins to form. It is in the ſame way that the epilepſy is produced, which is ſometimes the conſequence of caſtration. (See Theden's Bermerkungen). The method by which the blindneſs has ſometimes been removed, likewiſe increaſes the probability of this account. This kind of amauroſis has occaſionally been cured by ſtrong frictions upon the eye-brow (Platner), and alſo by frequently rubbing the ſame part, for a conſiderable time, with ſoftening emollient oils and ointments.

It is adviſable, in all wounds of the eye-brow, to prevent ſuppuration by healing them by the firſt intention. When matter cannot be hindered from forming, we ſhould endea-

vour

vour to avoid every thing likely to make the ſuppuration more extenſive, and the conſequent cicatrix larger. Should the wound be already healed, and the blindneſs have come on, we muſt put in practice ſuch means as have, in ſome inſtance or another, been found ſucceſsful. Hence emollient oils and ointments ought to be ſtrongly and frequently rubbed on the eye-brow, eſpecially in the ſituation of the ſcar. Emollient fomentations may likewiſe be employed with a proſpect of benefit. As this ſort of amauroſis evidently originates from nervous irritation, Richter queſtions, whether ſome good might not be derived from opium and other antiſpaſmodic remedies? And whether, in the event of this plan failing, benefit might not be expected from making a diviſion of the nerve? (Anfangſgr. der Wundarzneykunſt, Band 2).

It is rather to the practice, than the theories, of the continental ſurgeons, in caſes of amauroſis, that we are anxious to excite the reader's attention. We do not deſire him to believe, that checking a rheumatiſm, a gouty attack, an itch, or a gonorrhœa, has ever really been the cauſe of a gutta ſerena. As we know that ſuch diſeaſes cannot make a perſon inſuſceptible of the latter diſorder, ſo we can readily conceive, that, in many caſes, the blindneſs may begin about the time when a rheumatiſm, a clap, an itch, &c. are giving way to their particular remedies. When Richter informs us, that an amauroſis, attended with conſiderable weeping and irritability of the eye, and originating after the repreſſion of a rheumatiſm, was cured by bliſtering the eye-brow and adminiſtering to the patient thrice a day from twenty to forty drops of a mixture, compoſed of an ounce of antimonial wine and half a dram of the extractum aconiti, we do not wiſh the reader to credit the alleged cauſe of the blindneſs, but only to recollect the ſucceſsful mode of treatment. When valerian is ſtated to have cured a gutta ſerena, which followed the repreſſion of an itchy eruption, the reader is only required to attend to the practice, and he may diſmiſs as much of the theory as he likes.

The third ſpecies of the gutta ſerena, or that which ariſes from debilitating cauſes, is of two kinds: ſometimes the diſeaſe is the conſequence of a general weakneſs of the body, while, in other inſtances, it is the effect of a debility, which is confined to the eye itſelf, and does not extend to the whole conſtitution. In the firſt caſe, nouriſhing food, and tonic remedies, eſpecially bark, ſteel, and cold bathing, are the moſt beneficial, while, at the ſame time, topical corroborants may alſo be employed. In the ſecond kind of caſe, theſe laſt means alone are neceſſary. Bathing the eye with cold water is one of the moſt powerful local means of ſtrengthening the eye. The patient ſhould dip in cold water a compreſs, doubled into eight folds, and ſufficiently large to cover the whole face and forehead, and this he ſhould keep applied as long as it continues cold. Or elſe, he ſhould apply cold water frequently to his eyes and face with his hand, or a piece of rag. He may alſo bathe the whole of his head with cold water. Richter does not approve of employing in theſe caſes eye-glaſſes for bathing this organ; he objects to their ſmallneſs, from which the eye ſoon makes the fluid warm, or preſſes the greater part of it out. The eye is alſo remarkably ſtrengthened by repeatedly applying bliſters, of a ſemilunar ſhape, above the eye-brows, ſometimes in one place, ſometimes in another. However, Richter adviſes the bliſter only to be allowed to remain on the part juſt long enough to produce redreſs, without occaſioning a veſication. He alſo recommends rubbing the upper eye-lid, ſeveral times a day, with a mixture of the tinctura cantharidum and ſpiritus ſerpilli, in equal proportions, great care being taken that none of the application come into contact with the eye. All ſpirituous and aromatic remedies are likewiſe proper, which have the quality of ſtrengthening this organ. The infuſum valerianæ et ſalviæ, with a fourth part of camphorated ſpirit, Richter ſpeaks of as an uſeful application, with which the eye-lids, and parts around the eye, may be repeatedly rubbed. He alſo recommends ſmearing the upper eye-lid now and then with the oleum cajeput.

When no probable cauſe whatſoever can be aſſigned for the diſeaſe, the ſurgeon is juſtified in employing ſuch remedies as have been proved by experience to be capable ſometimes of relieving the affection, although upon what principle is utterly unknown. The chief means of this kind are emetics, given in ſmall doſes to excite nauſea, and occaſionally in larger ones to occaſion vomiting. A ſimple ſolution of two grains of the antimonium tartarizatum in a few ounces of water, taken by ſpoonfuls, frequently proves productive of remarkable benefit. Experience is alſo highly in favour of giving a trial to Schmucker's pills, the compoſition of which has already been deſcribed in the preſent article. The operation of theſe pills may be greatly aſſiſted with the exhibition of arnica and valerian, ſixteen grains of which ſhould be taken every morning and evening, and the doſe gradually increaſed. The leaves and flowers of arnica in an infuſion, or elſe in powder, have been found efficacious. Of the laſt, at firſt ten grains, afterwards gradually increaſed to half a dram, may be preſcribed every two or four hours. Arnica has likewiſe been found uſeful conjoined with roſemary. Mercury may be alſo given by itſelf till the commencement of a ſalivation, or conjoined with ſarſaparilla, powder of cicuta, or the ſulphur auratum antimonii.

Valerian alone, in the form of powder, and in the doſe of a half a dram ſeveral times a day, may alſo be tried. Or this medicine may be joined with a decoction of bark, containing either ſome of the ammonia præparata, or a proper proportion of the ſpiritus ætheris vitriolici compoſitus. Snuff may be taken up the noſtrils, or may be uſed as an ingredient in a collyrium, of which one-third ſhould be camphorated ſpirit. Stork has recommended pulſatilla, in the form of an extract, of which from half a grain to two grains is to be taken with ſugar, or antimonial wine, or an infuſion of this plant may be given. The extractum hyoſcyami albi is ſaid to be an excellent remedy, either alone, in the doſe of from two to eight grains twice a day, or together with antimonial wine. A ſort of tincture of millepedes is among the empirical medicines in repute upon the continent for its efficacy in caſes of gutta ſerena. Hemlock is another celebrated remedy. So is the powder of belladonna, given in the doſe of five grains a day. The ammonia præparata, in the doſe of a ſcruple once a day, is likewiſe praiſed. Externally, the aqua ammoniæ acetatæ mixed with ſage, or ſetwell tea, may be uſed as a collyrium. A mixture of oleum caſtorei and hartſhorn, in equal parts, may be taken inwardly in the doſe of forty drops, and alſo rubbed on the upper eye-lid and the eye-brow. Warner exhibited the oleum animale and muſk. (See Anfangſgrunde der Wundarzneykunſt. Band 3.)

Electricity has been ſtrongly recommended as a remedy for the gutta ſerena by Mr. Hey. (See Medical Obſervations and Enquiries, vol. v. Mem. of the Med. Society, vol. iii.) Sparks may be drawn from the eyes, or electrical ſhocks may be given to the patient. With the exception of one caſe, related by Valſalva, Scarpa tells us, that he is unacquainted with any amauroſis, occaſioned by a wound of the eye-brow, yielding to ſurgery. However, one of the examples, recorded by Mr. Hey, was of this kind, and yet was cured by electricity, and adminiſtering every night the following

following medicine: ℞ Calomel. Camph. ā ā gr. iij. Conferv. Cynoſb. q. s. probe miſceant et fiant bolus. The patient, who was a lady, had been previouſly bled twice, and had taken ſome nervous medicines. She was placed upon a ſtool with glaſs feet, and had ſparks drawn from her eyes, and the parts about the orbits, particularly where the ſuperciliary and infra-orbitary nerves ramify. After this operation had been continued half an hour, ſhe was made to receive, for an equal time, ſlight ſhocks through the affected parts. In a few days, ſight began to return, and in leſs than three months it was quite reſtored. In another caſe, one grain of calomel and two of camphor, adminiſtered every night in conjunction with electricity, effected a cure. The diſeaſe had come on gradually, without any previous accident or pains in the head. The patient was a boy nine years of age.

Mr. Hey has recorded ſeveral other intereſting caſes of amauroſis, all of which tend to prove electricity a powerful remedy for this diſeaſe, though it is true, as Scarpa has obſerved, that in moſt of the inſtances adduced by Mr. Hey, internal medicines were given, and bleeding practiſed, beſides electricity. The laſt author was led to impute ſo much efficacy to the electricity, becauſe, in two of the caſes, no medicines were employed, and yet the progreſs of the amendment ſeemed to be as quick in them as in the other examples, and becauſe, in two inſtances, a degree of ſight was obtained by the firſt application of electricity. We believe it was Mr. Hey who firſt noticed the obliquity of ſight, which is invariably attendant on amauroſis. He informs us, that it was moſt remarkable in thoſe patients who had totally loſt the ſight of either eye; for in them the oblique rays of light ſeemed to make the firſt ſenſible impreſſion upon the retina; and, in proportion as that nervous coat regained ſenſibility, the ſight became more direct and natural.

Mr. Ware has recommended electricity, and the uſe of a mercurial ſnuff, for the cure of the gutta ſerena. The ſnuff is compounded of ten grains of turbith. mineral (hydrargyrus ſulphuratus), well mixed, with about a dram of the pulvis ſternutatorius, glycirrhiza, or common ſugar. A ſmall pinch of this ſnuff is found to ſtimulate the noſe very conſiderably, ſometimes exciting ſneezing, but, in general, producing a very large diſcharge of mucus.

According to Mr. Ware, the caſes which receive benefit from electricity are generally attended with a dilated ſtate of the pupil. However, he notices that there are many inſtances in which a contraction of the pupil is the only change which takes place in the appearance of the eye. In this ſort of caſe, the impairment of ſight is uſually preceded by ſevere pain, and the original cauſe may be an internal ophthalmy of long continuance. The cryſtalline is ſometimes, ſays Mr. Ware, viſibly opaque. Here electricity has been found uſeful; though this eminent oculiſt at the ſame time beſtows a higher commendation on the ſublimate, which is ſaid to have proved ſuperiorly and more certainly efficacious, and which the ſame gentleman conſequently prefers to all other external applications whatſoever. He adviſes giving one-fourth of a grain, as a proper ordinary doſe, and aſſures us, that it agrees beſt with the ſtomach, when firſt diſſolved, as Van Swieten directs, in half an ounce of brandy, and taken in a baſon of ſago or gruel. For young patients, the doſe muſt be leſs in proportion to their early age. The medicine is to be continued as uninterruptedly as the conſtitution will allow, for a month, ſix weeks, or even longer.

If Mr. Ware's obſervations are correct, electricity has proved more ſtrikingly uſeful in caſes of gutta ſerena originating from lightning, than in any other ſpecies of the diſorder.

This author makes us acquainted with a very intereſting example in which the efficacy of electricity was demonſtrated. The diſeaſe made its attack very ſuddenly, on the ſubſidence of a ſevere pain in the teeth and ſwelling of the face. The affection came on more ſuddenly; the temporary blindneſs was more entire; the eye-lids were more affected; and the cure more ſpeedy, than in the examples recorded by Mr. Hey in the fifth volume of the Medical Obſervations and Enquiries. (See Chirurgical Obſervations relative to the Eye, vol. i.)

Schmucker preſcribes a ſternutative powder made of mercury, ſugar, and valerian.

Beſides irritating the Schneiderian membrane, ſtimulating applications may be rubbed on the upper eye-lid, and on the parts about the eye-brows. Two drops of fennel, or cajeput oil, may be uſed in this manner, or elſe a little hartſhorn.

Cantharides are alſo of eminent uſe in numerous caſes of gutta ſerena, eſpecially the bliſtering plaſter which is made of them. This may be applied alternately behind the ears and over the eye-brows for a length of time; or the tinctura cantharidum diluted may be rubbed about the eye-brows, until redneſs and ſwelling are excited. Since, alſo, the internal uſe of cantharides has been found ſerviceable in ſome paralytic affections, (ſee Briſbane's Select Caſes, &c.), it is not unreaſonable to infer, that the ſame remedy may ſometimes do good in caſes of amauroſis. From ten to twenty drops of the tinctura lyttæ may be adminiſtered, twice a day, in any convenient vehicle.

The ſhower bath, which has proved uſeful in other weakneſſes and paralytic diſorders, may likewiſe be of ſervice in ſome caſes of gutta ſerena.

Abroad, cauteriſing the parts about the eye-brow with a heated iron, or the moxa, is ſometimes practiſed, and, as is aſſerted, with beneficial effects. We would not wiſh, however, to ſee the uſe of actual fire again revived among Engliſh ſurgeons.

Richter informs us of a man, who was completely blind, recovering his ſight by having his eyes expoſed ſeveral times a day, for a quarter of an hour at a time, to the vivid rays of the ſun. When the patient had regained ſuch ſenſibility in the eyes, that the light of the ſun was annoying, he was directed to keep theſe organs fixed on ſhining objects. Upon the the ſame principle, it is obſerved, deaf perſons have occaſionally had their hearing re-eſtabliſhed by ſome violent noiſe.

Sometimes, however, as Richter remarks, the foregoing empirical kinds of remedies admit of a rational choice being made in the employment of them. They may, for the moſt part, be divided into two claſſes, namely, ſtimulants and anodynes. The firſt is evidently the moſt advantageous, when the gutta ſerena originates from any debilitating cauſes, or from plethora of the veſſels, and ſtill continues notwithſtanding the removal of ſuch cauſes. Here the duration of the diſeaſe may be aſcribed to a torpid inactive ſtate of the nerves, and ſome benefit may be expected from ſtimulants, ſuch as bliſters, emetics, ſternutatories, electricity, &c. The ſecond claſs of empirical remedies, which leſſen the effects of irritation, ſeems the moſt proper, when the amauroſis has ariſen from ſome irritating cauſe, and continues, notwithſtanding ſuch cauſe is removed. He is of opinion, that the continuation of the diſeaſe may be aſcribed to the impreſſion which the irritation has left upon the nerves, and that benefit may be expected from the uſe of ſuch remedies as tend to diminiſh ſuch impreſſion, as, for inſtance, the extract of the hyoſcyamus albus, the volatile alkali, hemlock, valerian, &c.

Sometimes,

Sometimes, as we have already explained, ſymptoms and appearances occur in the courſe of the caſe, which aſſiſt the ſurgeon in making a choice of the means of cure, and lead him to give a preference to this or that empirical remedy, or to ſome other of a ſimilar claſs. For inſtance, the practitioner may occaſionally remark ſymptoms of preternatural irritation, or of unuſual ſenſibility in the eye; the patient ſees ſeveral kinds of coloured or ſhining objects; his eye is painful, and though he is quite blind, he cannot bear a ſtrong light; the pupil is conſiderably contracted; the patient has a beginning amauroſis, and can diſcern better in a dark than a light ſituation. When the ſurgeon cannot detect any particular cauſe of this irritability, he is juſtified in employing ſuch general means as tend to diminiſh irritability, and leſſen irritation. A decoction of white poppy heads may be uſed as a collyrium lukewarm. The extractum hyoſcyami albi, belladonna, cicuta, valerian, bark, gum. ammon. galbanum, oleum cajeput, and opium, eſpecially the tincture with antimonial wine, are all proper medicines in the preceding ſort of caſe.

Sometimes the gutta ſerena ariſes with ſymptoms which indicate weakneſs and diminiſhed ſenſibility of the eye. While the patient continues not entirely blind, he finds his ſight cloudy, he ſees better in a light than a dark ſituation, and feels a ſort of languor in the eye. He experiences a ſenſation, as if ſome dirt were in his eyes, and is frequently endeavouring to wipe it away. He finds himſelf able to ſee better juſt after meals, or whenever he has been having recourſe to external corroborant remedies. Such circumſtances direct the ſurgeon to employ tonics and ſtimulants, when all debilitating cauſes are quite undiſcoverable. Bark, ammonia præparata, valerian, cold water, arnica, cantharides, ſpirituous and aromatic external remedies, &c. are proper.

Sometimes, as Richter further informs us, the ſymptoms ſeem to indicate a preternatural accumulation of fluid in the eye. The patient complains of the eye-ball being tenſe, and of a ſenſation as if there was not room enough in the orbit for the globe of the eye. The eye-ball ſeems to the patient ſtiff, immoveable, and harder than uſual. All kinds of evacuations, bliſters over the eye-brows, behind the ears, and upon the nape of the neck, kept open or frequently repeated; large doſes of emetics, ſetons, iſſues, and ſternutatories, are now the right remedies: Richter thinks, that even dividing the cornea, and letting out the aqueous humour, might, in this inſtance, be advantageous. At all events, in his opinion, it could not be productive of any harm. This ſlight operation, however, muſt either be repeated every day for a few days, or elſe the firſt opening muſt be prevented from cloſing, in order that the fulneſs of the eye may continue, for a certain time, in a diminiſhed ſtate.

The external and internal veſſels of the eye ſometimes, ſays Richter, ſeem to be in a varicoſe condition. The patient ſees immoveable black ſpots, which gradually become larger and more numerous, net-like figures, and ſeveral other unchangeable ſhadowy appearances. The veſſels of the conjunctiva are ſwollen, without being inflamed. Repeated general and topical bleeding, ſcarifying the varicoſe veſſels of the conjunctiva, bathing the eye with cold water, &c. are the moſt ſuitable means in the preſent caſe.

The ſame author alſo remarks, that ſome patients, for a certain ſpace of time, before the diſeaſe, are afflicted with frequent catarrhal diſcharges from the noſe, and, when the blindneſs comes on, feel an unuſual dryneſs in the noſe, uneaſineſs about the root of this part and the frontal ſinuſes. Here ſternutatories are indicated. The ſnuff recommended by Mr. Ware may be employed, or elſe that uſed by Schmucker, and thus compoſed: ℞ Mercur. Viv. drachm. ʃ Sacchar. Alb. dr. iij pulv. Lill. Alb. Rad. Valerian. ā ā dr. j Miſce. The patient may alſo apply to his noſtrils the ſteam of any emollient decoction, containing a proportion of valerian.

In thoſe caſes in which a white, or light-coloured appearance is obſervable at the bottom of the eye, the retina itſelf is probably thickened and diſeaſed. Here ſuch medicines as cicuta, belladonna, mercury, aqua ammoniæ, &c. may be tried.

In certain inſtances, amauroſis comes on, attended with an obſtinate, frequently returning ophthalmy. When there is no manifeſt cauſe for ſuch inflammation, antimonials, mercurials, and anodynes may be employed.

Richter next obſerves, that, with reſpect to the periodical amauroſis, although it is common to preſcribe bark; yet, ſince the diſorder may proceed from a variety of cauſes, bark can be of no ſervice, and may even do harm, and lengthen the attacks of the diſeaſe, while ſuch cauſes continue unremoved. The cauſe of the periodical amauroſis is moſt frequently in the viſcera of the abdomen. A man, who uſed to be blind every morning, ſays Richter, always felt at the ſame time a ſevere pain juſt under the falſe ribs, on the right ſide. The attacks always terminated with the diſcharge of a large quantity of air from the bowels. Hence it is generally proper, in ſuch caſes, to clear out the alimentary canal, and it is only when this has been accompliſhed that bark can prove uſeful. Frequently, alſo, valerian, arnica, or ſmall doſes of ipecacuanha, may then be adminiſtered with advantage.

Sometimes the periodical amauroſis originates from worms, or from an interruption of the menſtrual diſcharge. Theſe caſes demand a mode of treatment already deſcribed. Occaſionally, the gutta ſerena is connected with hyſterical complaints, with which it ſubſides. The remedies for hyſteria are here the proper remedies for the blindneſs. The oleum cajeput has been found ſerviceable. (See Richter's Anfangſgrunde der Wundarzneykunſt. Band 3, Kapitel 14).

Some caſes of gutta ſerena are, from their nature, incurable. Of this kind may be deemed ſuch as depend upon tumours ſituated in the cerebrum, and compreſſing the optic nerves; ſuch as depend upon original malformations of the optic nerves; ſuch as proceed from a permanent alteration of the optic foramen in conſequence of caries, &c.

Some additional obſervations, connected with the ſubject of gutta ſerena, will be found under the heads HEMERALOPIA and NYCTALOPIA.

The late Mr. Ferguſon contrived an inſtrument for applying the power of electricity to diſorders in the eyes: this inſtrument conſiſts of a pointed braſs wire, faſtened by means of a cork at the ſmaller end of a conical glaſs, open at both ends, and paſſing through the axis of this glaſs, ſo that its point comes within about half an inch of the larger aperture of the glaſs: the inſtrument is to be ſo fixed, that the larger aperture of the glaſs may ſurround the eye, and keep its lid open, and the point of the wire is directed to the pupil, and at the diſtance of about half an inch or an inch from it. In the uſe of this inſtrument a ſpark often proceeds from the point of the wire, which occaſions very acute pain; and, therefore, Mr. Partington fixed a wooden point upon the pointed wire; but the directors of this laſt gentleman are better adapted to the purpoſe.

GUTTÆ *Anglicanæ*, *Engliſh drops*, *volatile Engliſh drops*, or *Goddard's drops*, a name of a medicinal liquor, prepared from divers ingredients, formerly ſuppoſed to be of ſove-

reign

reign efficacy againſt coagulations of the blood, malignant fevers, and particularly the ſmall-pox, obſtructions, epilepſies, drowſy diſeaſes, vapours, &c.

The inventor of theſe celebrated drops was Dr. Goddard, a phyſician of London. The ſecret of their compoſition was purchaſed by king Charles II. at the price of 50,000*l.* ſterl. whence they were denominated *guttæ Anglicanæ*.

This coſtly receipt we ſhall here gratify the reader with, *a meilleur marche:* "Take five pounds of human cranium, of a perſon hanged, or dead of ſome violent death, two pounds of dried vipers, two pounds of hartſhorn, and two of ivory; mince the whole ſmall, put it in two or three retorts, and diſtil it in a reverberatory furnace, with the ſame precautions as are ordinarily uſed in diſtilling hartſhorn and vipers, to extract their volatile ſalt. When the veſſels or receivers are cold, unlute them, and ſhake them well, in order to looſen the volatile ſalts from the ſides of the veſſels. Pour the whole in a large glaſs cucurbit, and filtrate it through a brown paper, in order to ſeparate the oil, which is here uſeleſs: put the filtrated liquor in a glaſs retort, and place it in a ſand heat, and fit another glaſs retort thereto, as a recipient; take care all things be well luted, and make a cohobation of the ſaid matters at three times. But, by the way, add all the ſalt before ſeparated from the receivers; and after the ſaid three cohobations, unlute the retorts, and pour the whole into a matraſs with a long neck, to which fix a ſuitable capital, and a receiver; lute all the joinings on each ſide with a wet bladder, and ſet the veſſel in a ſand heat; by this means, the volatile ſalt will be ſublimed, and ſtick to the capital and upper part of the matraſs. Continue the fire till ſpirit enough hath riſen to diffuſe and diſſolve the ſalt which aroſe firſt: then take all the fire out of the furnace, that the diſtillation may proceed no farther, which is a circumſtance of the laſt importance, without which the medicine would be weakened by too much phlegm." Biet. in Mem. de Trev. 1713.

As to the doſe of this remedy, they begin with ſeven or eight drops, increaſing by degrees to forty or fifty, on preſſing occaſions, as in apoplexies, lethargies, weakneſſes, &c.

The real compoſition of the guttæ, however, is ſomewhat controverted. Dr. Liſter aſſures us, that he had the ſecret communicated to him by king Charles II. that it is no other than the volatile ſpirit of raw ſilk, rectified with oil of cinnamon, or ſome other eſſential oil.

The ſame author aſſures us, he had found by experience, that the guttæ Anglicanæ were not in any reſpect preferable to the common volatile ſpirits of hartſhorn and ſal ammoniac, except that the ſmell is more ſupportable. Mem. de l'Acad. des Scien. ann. 1700.

GUTTÆ, in *Architecture*, are ornaments in form of little cones, in the plafond of the Doric cornice, on the architrave, underneath the triglyphs, repreſenting a ſort of drops or bells; they are uſually ſix in number. They are ſometimes alſo called *lachrymæ*, *tears*; and *campanæ* or *campanulæ*, *bells*. Leon Baptiſta Alberti calls them *nails*. See DROPS.

GUTTE. See GUTTY.

GUTTEMBERG, JOHN, in *Biography*, regarded as the inventor of the noble art of printing, was born at Mentz about the year 1400. Much has been ſaid with reſpect to the author of this invention, who is now generally given as the ſubject of the preſent article: the controverſy will, however, be conſidered more at large when we come to the word PRINTING. It appears, by a public document entitled "An Enquiry, ordered by the Senate of Straſburg, in regard to the Suit carried on againſt John Guttemberg, &c. in 1439," that he was the inventor of typography, that he had at this period a preſs mounted, and that in this preſs there were forms, locked by ſcrews, which ſhew that the types were moveable. The characters which he employed were cut out of wood, though he ſometimes uſed lead, or ſome other harder metal, for his types. In the year 1465, Guttemberg was honoured by the archbiſhop Adolphus with a mark of diſtinction, to which his genius and labour entitled him. He was admitted among the nobility of his court, allowed to wear the dreſs peculiar to that order, and had a penſion, together with ſeveral privileges and exemptions, conferred upon him. Guttemberg is ſuppoſed to have died in the year 1467 or 1468. He was interred in the church of Recollets at Mentz, and the following epitaph was placed over or near his tomb. "D.O.M.S, Johanni Gensfleiſch, (from the name of his houſe,) artis impreſſoriæ repertori, de omni natione et lingua optime merito, in nominis ſui memoriam immortalem, Adam Gelthus poſuit." Over another houſe, in which Guttemberg lived, was placed the following inſcription in the year 1507.

JOANNI GUTTEMBERGENSI
MOGUNTINO,
QUI PRIMUS OMNIUM LITERAS ÆRE
IMPRIMENDAS INVENIT
HAC ARTE DE ORBE TOTO BENE MERENTI;
IVO VINTIGENSIS
HOC SAXUM PRO MONUMENTO POSUIT.

GUTTER, in *Geography*, a ſea-port of Perſia, in the province of Mecran; ſituated in a bay of the Arabian ſea; 40 miles W. of Guadel. N. lat. 25 18'. E long. 61° 15'.—Alſo, a ſmall iſland in the Arabian ſea, near the coaſt of Perſia. N. lat. 25° 15'. E. long. 61° 10'.

GUTTER, in *Agriculture*, a narrow ditch, trench, or furrow, formed in any kind of ground for the purpoſe of draining it. It may be moſt conveniently formed by the plough, and ſpades proper for the purpoſe.

GUTTER, in *Building*, a channel for collecting and conveying the water from the roof, ſituated between the parapet and the inclined ſide of the covering, or between the inclined ſides of a double roof, the interſection of the vertical plane of the wall and the inclined plane of the roof, or the two inclined planes forming horizontal lines. When two inclined ſides of a roof meet each other at an internal angle, and form an inclined interſection to the horizon, the angle thus formed is called a valley. The external angles formed by two inclined planes are called hips; and hence hips are exactly the reverſe of vallies, and thus we have the difference between gutters, hips, and vallies. The interſection of the planes which form the ſides of gutters are horizontal, but the interſection of the planes which form hips and vallies are inclined.

Gutters for lead are formed partly by a boarding perpendicular to the plane of the walls, and partly by the inclined ſides of the roof and the vertical planes of the walls, and are ſupported by horizontal bearers from the walls to the ſides of the rafters, againſt which they are nailed at one end; the other end is ſupported cloſe to the wall upon ſmall poſts or puncheons, which are notched and nailed to the bearers. The boarding which is ſupported by the bearers, and which ſtands perpendicular to the planes of the walls, forms the bottom of the gutter, and is laid with a declivity in the parallel direction of the plane of the wall, of about an inch in ten feet, and with ſteps called drips at every twelve or eighteen feet. The drips are formed in planes perpendicular to the horizon and to the walls, riſing about two, or two and a half inches, ſo as to add to the deſcent of the gutters, and at ſuch diſtances from each other as are equal to the

the length of the ſheets. Gutters are laid with lead of ſuch weight, that the ſuperficial foot contains from ſeven to twelve pounds, according to the ſtreſs that is ſuppoſed to be on the ſurface. The ſheets are laid from twelve to eighteen feet in length, as the deſcent for the water may permit. When there is a ſufficient current for the water, ſhorter ſheets of twelve feet in length are to be recommended in preference to longer ones, on account of the latter ſometimes cracking by expanſion, as all metals are liable to do. Caſt lead is preferable to milled lead, as being more ſolid in its texture, and on this account is more to be depended upon when it expands, ſo as to keep from tearing aſunder; but milled lead is equally thick throughout, and has its ſurface regularly ſmooth, properties which, however, are not to be found in caſt lead; therefore, wherever beauty and neatneſs of workmanſhip are required, milled lead muſt be employed. The goodneſs of caſt lead depends upon the equality of its thickneſs, which cannot at all times be depended upon, and it is but juſtice to inform the reader that plumbers themſelves are divided in their opinion whether caſt or milled lead ought to have the preference.

In London, parapet walls and leaden gutters are indiſpenſible, on account of the building act, as the numerous inhabitants are leſs liable to accidents from the falling of broken ſlates or tiles; and in caſes of fire in the lower part of the building, they are convenient for making an eſcape from the danger, and alſo for aſſiſting in extinguiſhing the flames. Several attempts have been made to ſubſtitute copper, but this material has not been found to have the deſired effect. The water is conveyed from the gutters by leaden pipes.

In the country, dripping-eaves are much uſed, and to be preferred in elevated ſituations, as in the winter ſeaſon the gutters and pipes are frequently ſtopped by ſnow or froſt, ſo as to bring down the ceilings and plaſtering, injure the walls, and rot the timber; and thus not only render the building unfit for living in, but reduce it to ruin in the courſe of a few years. On this account, many of the firſt rate houſes ſuffer much by the overflowing of the water, unleſs the gutters areſo conſtructed that the water may eſcape before it finds its way into the building. Gutters ſhould never be ſoldered where it can be avoided, particularly when the ſoldering would make the ſheets of unuſual length, as in this caſe it would be impoſſible to enſure it from cracking; the expences of repairing would be frequent, and the ultimate effect would be ruinous. The thickeſt lead is uſed in gutters and flats, each generally of the ſame weight, while the hips and ridges are from five to ſix pound to the foot, and moſt generally of milled lead.

Gutter, in *Mining*, ſignifies in Staffordſhire, and ſome other places, a ſlough, adit, level, or ſubterraneous drain to a mine.

Gutter and *Blaſt*, denotes one of the modes of working a hard vein of lead ore, which conſiſts in picking out or cutting a gutter or vertical nick in the vein-ſtuff on one ſide of the rib of ore or vein, and then ſetting a ſhot or ſhots on the other ſide, in order to blaſt out the ore, &c.

Gutter-*ledge* is the name of a croſs-bar, laid along the middle of a hatch-way in ſome ſhips, for ſupporting the covers, and any weighty body that may be laid or moved upon them.

Gutter *Tyles*. See Tyle.

GUTTERANA, in *Geography*, a town of Hindooſtan, in the circar of Sanore; 15 miles E. of Sanore.

GUTTERING *of* Land, in *Agriculture*, the forming of drains of the gutter kind in lands, either by the plough or the ſpade, ſo as to free them from overabundant moiſture.

Gutter*ing Plough*, the name of a ſmall and ſimple plough of the draining kind, that is much employed on wet lands in ſome diſtricts. It is capable of being wrought by a ſingle horſe or a man. A trench or opening, four or five inches in breadth, and ſix or eight inches in depth, may by this means be readily formed; on which account it is much employed in making drains in bleaching and other ſimilar grounds, and may do very well for wet clayey meadow land, where the ſoil is ſhallow, and liable to the production of ruſhes and other coarſe plants.

The tool conſiſts of a piece of iron, about five inches in breadth, and pointed at the end: upon this piece two other pieces are fixed perpendicularly to the former, one on each ſide, the fore edges inclining backwards; ſo that the three edges of the inſtrument form a ſort of letter A: and to the bottom plate is fixed a ſocket for receiving the ſtale or handle, which is ſet higher or lower by means of a wedge on the under ſide. At the end of the ſtale is a croſs piece three feet in length, againſt which the man's breaſt is placed, when he ſhoves the tool before him in cutting the drain. A rib, twenty-four inches long, is fixed on the ſocket, at the end of it; a peg, about a foot long, and two inches in diameter, is faſtened to the ſide of the ſtale by ſcrews. This peg reſts on the land when the clod is turned out of the tool. See Plough-*draining*.

GUTTETÆ Pulvis, is the name of an epileptic powder in the Paris Pharmacopœia, compoſed of miſletoe of the oak, roots of white dittany, the root and ſeed of peony, of each half an ounce; the ſeeds of gooſe-foot, two drams; human ſkull, three drams; red coral prepared, two drams; the horns of elk's foot, half an ounce; and a ſcruple of gold leaf: all which ingredients are to be reduced to a fine powder. This powder has been deemed a very powerful antiſpaſmodic, and is ſaid to have been adminiſtered in the quantity of a ſcruple for a doſe, for a conſiderable time, with great ſucceſs in the epilepſy.

GUTTIFERÆ, in *Botany*, ſo called by Juſſieu, becauſe of the gum or reſin for which ſome of them are noted, a Natural Order of Plants, the 69th in the ſyſtem of that diſtinguiſhed author, and the 9th of his 13th claſs. For the full characters of this claſs, ſee Gerania.

The order of *Guttiferæ* is thus defined. *Calyx* either of a definite number of leaves, or of one leaf deeply divided, or very rarely wanting. *Petals* definite in number, often four. *Stamens* moſtly indefinite, rarely definite, their filaments ſometimes diſtinct, ſometimes, but more rarely, monadelphous, or polyadelphous; their anthers incorporated with the filaments. *Germen* ſimple; ſtyle ſimple or none; ſtigma ſimple or divided. *Fruit* moſtly of one cell, either a berry or drupa, or capſular, in ſome caſes entire, in others burſting by valves, and containing one or many *ſeeds*, ſometimes attached to the central receptacle, ſometimes to the enclofing part. *Corculum* ſtraight, without any albumen, its lobes ſomewhat callous or corky. The *plants* are either trees or ſhrubs, many of them abounding with reſinous juice. *Leaves* moſtly oppoſite, generally coriaceous, undivided, ſmooth, with one central longitudinal nerve, the reſt tranſverſe. *Flowers* axillary or terminal, occaſionally monoecious or dioecious by abortion of parts.

The firſt ſection conſiſts of ſix genera, which have no ſtyle; *Cambogia* adopted from Rheede and Linnæus; *Cluſia*; *Garcinia*; *Tovomita*, Aubl t. 364; *Xanthe* of Schreber, which is *Quapoya* of Aubl. t. 343, 344; and *Grias*. See the latter, which we have preſumed to remove to another order.

Section ſecond, flowers with one ſtyle, comprehends eight genera; *Symphonia* of Schreber, which is *Moronobea* of Aubl. t. 313; *Macoubea*, Aubl. t. 378, a genus with which

no other perſon has ventured to meddle, all parts of the flower being unknown; *Mammea; Macanea*, or *Macahanea*, Aubl. t. 371, of whoſe flower there is no account; *Sterbeckia* of Schreber, which is *Singana* of Aubl. t. 230; *Meſua; Rheedia;* and *Calophyllum.*

The third ſection conſiſts of four genera, whoſe leaves are alternate, and which are judged for that reaſon akin to the next order, *Aurantia.* Theſe are *Vateria; Elæocarpus; Vatica;* and *Allophyllus.*

GUTTSTADT, in *Geography*, a town of Pruſſia, in Ermeland; 64 miles S. of Konigſberg.

GUTTURAL Letters, are thoſe pronounced or formed, as it were, in the throat.

Dr. Wallis diſtinguiſhes the vowels in our language into labial, palatine, and guttural; according to the ſeveral degrees of opening the mouth to pronounce them, larger, middle, and leſs. On this footing he makes three guttural vowels, and three labial, and as many palatines.

The four guttural letters in Hebrew are א, ה, ח, and ע, formed into the technical word אהחע.

GUTTUROSUS Piscis, in *Ichthyology*, a ſmall fiſh common in the Mediterranean, and brought to market at Rome, Venice, and elſewhere; and called in different parts *gotoroſala, gottorugine*, and *gotto di mare.*

GUTTUS, a term among antiquaries for a ſort of vaſe uſed in the Roman ſacrifices, to take the wine and ſprinkle it *guttatim*, drop by drop, upon the victim.

Vigenere on T. Livy gives the figure of the guttus, as repreſented on divers medals, and other ancient monuments.

GUTTY, or Gutte, in *Heraldry*, is when a thing is repreſented as charged or ſprinkled with drops.

In blazon, the colour of the drops is to be named; thus, gutty of ſable, of gules, &c.

Some authors will have red drops called *gutty de ſang*, or *drops of blood;* black ones, *gutty de poix, of pitch;* white, *gutty d'eau, of water*, &c.

GUTZKOW, in *Geography*, a town of Anterior Pomerania, capital of a country to which it gives name; 24 miles S. of Stralſund. N. lat. 53° 56′. E. long. 13° 23′.

GUUL, a river of Norway, which runs into Drontheim bay; 14 miles W. of Drontheim.

GUY, Thomas, in *Biography*, the founder of a noble hoſpital in Southwark, that bears his name, was the ſon of a lighterman and coal-dealer in Horſley-down. He was apprenticed to a bookſeller, and began trade with no larger ſtock than 200*l*; he was, however, induſtrious and ſucceſsful: but the bulk of his fortune was acquired by purchaſing ſeamen's tickets during the wars in queen Anne's reign, and by fortunate ſpeculations in the South-ſea ſtock, in the year 1720. Beſides Guy's hoſpital, he erected a wing to St. Thomas's hoſpital, and alſo an alms-houſe at Tamworth. He died in 1724, at the age of eighty-one, leaving behind him the vaſt ſum of 300,000*l*.

Guy, in *Geography*, a town of Hindooſtan, in Benares; 10 miles S. of Chunar.

Guy, in a *Ship*, is any rope uſed to keep off weighty bodies from bearing or falling againſt the ſhip's ſide, when they are to be hoiſted or lowered. Thus, if any thing is to be haled in over the gunwale, it is gently eaſed in by a *guy* rope, faſtened uſually to the ſtanchions of the waſte-trees.

Guy is likewiſe a large ſlack rope, extending from the head of the main-maſt to the head of the fore-maſt, and having two or three large blocks faſtened to the middle of it. This is chiefly employed to ſuſtain the tackle uſed for hoiſting in and out the cargo of a merchant-ſhip, and is removed from the maſt-heads as ſoon as the veſſel is laden or delivered. See Garnet.

Guy's *Hoſpital.* See Hospital.

GUYANDOT, in *Geography*, a river of America, in Virginia, which runs into the Ohio; N. lat. 38° 22′. W. long. 82° 20′.—Alſo, *Little Guyandot*, a river of Virginia, which runs into the Ohio; N. lat. 38° 14′. W. long. 81° 12′.

GUYERN, a town and caſtle of Germany, in the principality of Anſpach; 20 miles S.E. of Anſpach.

GUYON, Jeanne-Marie Bouvieres de la Mothe, in *Biography*, a female enthuſiaſt and myſtic of the 17th century, was born in 1648, at Montargis, of a reſpectable family; and at the age of 16 ſhe was married to the ſon of the celebrated Guyon, who obtained rank and fortune by his execution of the noble undertaking of the canal of Briare. At the age of 28 years, ſhe was left a widow with three children. She had always been diſtinguiſhed by deeds of charity, and a highly devotional turn of mind; and ſoon after the commencement of her widowhood, ſhe became acquainted at Paris with D'Arenthen, biſhop of Geneva, a prelate of ſingular worth and piety, who invited her to enter into a community of new Catholics, which was about to be eſtabliſhed in his dioceſe for the converſion of Proteſtant females. She complied with this propoſal, to the neglect of her young children, and to the ſurpriſe of her acquaintance. In this inſtitution, Madame Guyon renewed her acquaintance with Father Lacombe, a very devout Barnabite; who, having a turn of mind ſimilar to her own, inflamed her heated and elevated imagination, and confirmed her in the idea which ſhe had conceived, that ſhe was called to exerciſe an extraordinary miniſtry in the church. Indeed her whole life proved the mania of founding a myſtic aſſociation. Upon the application of her family, ſhe gave up a large ſettlement for the education of her children, and of her whole property reſerved to herſelf only a ſmall annuity. Leaving Gex, ſhe now followed Father Lacombe to the Chublais, and thence to Grenoble. This circumſtance gave riſe to the ſcandalous reports which were circulated at a ſubſequent period, and which Boſſuet endeavoured to employ to the prejudice of Fenelon, though the attempt ended in his own confuſion. In 1687, Madame Guyon returned to Paris, after an abſence of ſix years, which were conſumed in excurſions, conferences, and preachings. The principles ſhe inculcated were the entire renunciation of ſelf, the ſilence of the ſoul, the annihilation of all emotions, and a total indifference to life or death, future happineſs or miſery; and during this time ſhe publiſhed her two works, "An eaſy Method of Praying," and the "Myſtical Explication of the Songs of Solomon." Theſe performances were ſanctioned by very reſpectable names, but were generally conſidered as chargeable with extravagancies; and ſhe was arreſted on account of them, as well as on other grounds, and underwent various examinations by the official of the archbiſhop of Paris. On this and on all other inveſtigations of her proceedings, ſhe was freely acquitted of any moral irregularities; nevertheleſs ſhe remained in cuſtody in the convent of St. Mary. The ſiſters of that houſe were edified by her ſociety, and charmed with her converſation and behaviour; and their teſtimonies procured her great and powerful friends, all of whom ſhe was able to intereſt ſtrongly in her favour. The cautious and reflecting Madame de Maintenon was among the number who at length obtained her releaſe. Although the firſt accounts which archbiſhop Fenelon received of this lady had prepoſſeſſed him againſt her, yet upon paying her a viſit and inquiring into the courſe of her life, his unfavourable impreſſions were totally removed, and

and he was led to form a very high opinion of her piety and charity. He was afterwards introduced to her at the houſe of the ducheſſe de Beauvilliers, and upon repeated intercourſe ſhe gained a complete aſcendancy over his mind. Madame Maintenon had ſo high an eſteem for her, that ſhe was allowed to make frequent viſits to the convent of St. Cyr, where ſhe communicated her doctrines and her works. At length, however, Madame Maintenon became ſuſpicious, and upon conſulting her ſpiritual director, the biſhop of Chartres, ſhe became more cautious and guarded; and the pious Fenelon, much as he was prepoſſeſſed in favour of M. Guyon's doctrines and writings, concurred in recommending to withdraw the latter from the ſiſters of St. Cyr, and to diſcourage the prevalence of the former. About this time ſhe ſubmitted her works to the examination of Boſſuet, biſhop of Meaux, as it has been ſaid, by the advice of Fenelon; and ſhe alſo entruſted to the inſpection of the firſt named prelate, who afterwards betrayed her confidence, a MS. life, which contained many extravagances. In conſequence of an examination of her works by Boſſuet and other prelates, 34 articles were drawn up in condemnation of the myſteries of quietiſm, and Mad. Guyon, who had placed herſelf in a convent at Meaux, under the eye of the biſhop, her imagined friend, but in reality her enemy and perſecutor, was obliged, in 1695, to ſign theſe articles, and to teſtify her unqualified ſubmiſſion to the deciſions of the church. Upon her return to Paris, and her renewed zeal in making proſelytes, ſhe was confined at Vincennes, at Vaugirard, and finally in the Baſtile. When Fenelon, who was implicated in this buſineſs, as we have ſhewn under his article, made his ſubmiſſion, Mad. Guyon was liberated from the Baſtile in 1702, and then retired to Blois; where ſhe paſſed the remaining years of her life in obſcurity, and in the private exerciſes of a devotion, ſincere though enthuſiaſtic. She died with all the raptures of divine love which an ardent imagination could inſpire, in the year 1717, at the age of 69. To her teſtament ſhe prefixed a confeſſion of her faith, and an avowal of invariable obedience to the Catholic church. It cannot, however, be diſputed, that her fanaticiſm had much miſled her judgment, and that in her account of herſelf ſhe made pretenſions to a degree of perfection above the attainment of human nature in a ſtate of trial. Among her writings, we may mention "Chriſtian Diſcourſes," "The Old and New Teſtament, with Explanations and Reflections," 20 vols. 8vo.; "Spiritual Letters," and "Spiritual Songs and Nuptial Poems." To thoſe who are acquainted with the ſentiments and diſpoſition of the late excellent Mr. Cowper, whoſe character and poetical productions have claimed juſt approbation, it will not be ſurpriſing that he ſhould have cauſed to be ſelected, tranſlated, and printed ſome of the poems of Madame Guyon. Bauſſet's Hiſt. of Fenelon. Nouv. Dict. Hiſt. See FENELON and QUIETISTS.

GUYSBOROUGH, or MANCHESTER, in *Geography*, a townſhip of Nova Scotia, on Chedabucto bay, 10 leagues N.W. of Cape Canſo, and 40 leagues E. of Halifax, which in 1783 contained 250 families.

GUYSE, JOHN, in *Biography*, was born at Hertford in the year 1680, where he afterwards ſettled as a diſſenting miniſter. He was a zealous Trinitarian, and publiſhed ſome pieces in defence of the orthodox doctrine, as it was then, and ſtill is denominated. From Hertford he removed to London, and accepted an invitation to become paſtor of an Independent congregation in New Broad-ſtreet, with which he ſpent the remainder of his days, in the exemplary diſcharge of the duties connected with his office. In the year 1732 the univerſity of Aberdeen conferred on him the degree of doctor of divinity. His principal work was a paraphraſe on the New Teſtament, in three vols. 4to. which was completed in 1752. In the latter part of life Dr. Guyſe loſt his ſight, but as he was an extempore preacher, he continued his miniſterial duties till within a few months of his death, which happened in 1761, when he was in the eighty-firſt year of his age. He was author alſo of "The Youth's Monitor," "Sermons to young People," and other pieces.

GUZEL-HISAR, in *Geography*, a town of Aſiatic Turkey, in Natolia, anciently called "Magneſia Meandri," the reſidence of a pacha; divided into two parts by a river, anciently the "Lethæus." The air in the hot months is inſalubrious; 27 miles E.S.E. of Scalanova. N. lat. 37° 45'. E. long. 27 50'.—Alſo, a town of Natolia, near the W. coaſt; 15 miles N.E. of Fokia. N. lat. 38 48'. E. long. 26 54'.

GUZERAT, a peninſula of Hindooſtan, about 200 miles in length, and 140 wide, formed by the Arabian ſea, (called by the Aſiatics the "ſea of Omman,") and the gulfs of Cambay and Cutch, both of which penetrate far within the continent; ſubject to high and rapid tides, which throw up dangerous ſand-banks, and to the "bore," (which ſee,) which elevates the water many feet above the common ſurface of the ſea, and rages here with great violence. By the numerous ſubdiviſions of this tract, and ſtill more by the amount of its revenue, ſtated in the Ayin Acbaree, we are led to conſider it as of very great importance, in the opinion of the Moguls. This province, though the ſoil is dry and ſandy, and ſome parts of it are woody and mountainous, is one of the richeſt in the Mogul empire; abounding in rice, cotton, corn, ſugar, fruits of various kinds, with plenty of cattle and game. The rain is conſtant from the middle of June to the middle of September; but during the other months the air is clear and ſerene: and the abundance of night-dew refreſhes the plants, which are ſcorched by the rays of a hot ſun during the day. Guzerat contains a conſiderable number of towns, which have flouriſhing manufactures, and the woods are richly ſtored with timber fit for building. The greateſt part of it is occupied by the Poonah Mahrattas. The weſtern part of the peninſula is inhabited by a wild, hardy race, and they are governed by rajahs of their own, nor do they appear to have undergone much change by the late revolutions in Hindooſtan. The largeſt, as well as the fineſt part of Guzerat, is divided between the Paiſhwah, or head of the weſtern empire, reſiding at Poonah, (which ſee,) and Futty Sing Guicwar, or Guicker, who holds his ſhare chiefly in the northern part of it. (See MAHRATTAS.)

The fineſt part of this country was conquered by the Engliſh under general Goddard, but reſtored to the Mahrattas after the war with Hyder Ally. Guzerat, being a frontier province, as it reſpects the acceſs by ſea, contains a greater mixture of races, and a greater variety of religions, than any other province. Beſides Hindoos, the principal inhabitants, who follow the worſhip of the Bramins, this province is occupied by Moguls, Arabians, Perſians, Armenians, and Europeans. Its chief city is Amedabad, which ſucceeded Mahmoodabad, as the capital, ſituated on the banks of a ſmall river, called Sabermatty, and not Sabremelli, as is erroneouſly ſtated under the article *Ahmedabad*; which ſee.

GUZES, in *Heraldry*, roundles of a ſanguine or murry colour.

GUZGOOTY, in *Geography*, a town of Bengal; 8 miles N. of Rungpour.

GUZNOORGUL, a province of Aſia, belonging to Caferiſtan or Kuttore, lying on the W. of Bijore, and be-

tween it, and the Chuganſerai river, which forms the N.E. boundary of Cabul.

GWABR-MERCHED, in our *Old Writers*, a Britiſh word ſignifying a payment or fine, made to the lords of ſome manors, upon the marriage of their tenants' daughters; or otherwiſe, on their committing incontinency. See MARCHET.

GWAIF, or WAIF. See WAIF.

GWALIOR, in *Geography*, a celebrated fortreſs of Hindooſtan, in the circar of Gohud, ſtanding on a hill, $1\frac{6}{10}$ mile in length, and 300 yards in its greateſt breadth. The height at the N. end, where it is greateſt, is 342 feet. At this end is a palace, and about the middle of the fort are two remarkable pyramidal buildings of red ſtone, conſtructed in the ancient ſtyle of Hindoo architecture. A ſtone parapet runs all round, cloſe to the brow of the hill, which is ſo ſteep, that it was judged perfectly ſecure till major Popham took it by eſcalade, on the 3d of Auguſt 1780. The only gate is towards the northern extremity of the eaſt ſide, from which, by ſeveral flights of ſteps, you aſcend to the top of the rock. Within are ſeveral large natural cavities in the rock, which contain a perpetual ſupply of excellent water. On the outſide, about half way up, are many cells, which contain the figures of men and animals, carved, like the excavations, out of the ſolid rock. Along the eaſt ſide, near the ſummit, runs a line of blue enamel, very freſh and brilliant; a proof that this manufacture had attained conſiderable perfection in Hindooſtan at an early period. The town, which runs along the eaſt ſide of the hill, is large, well inhabited, and contains many good houſes of ſtone, abundantly furniſhed by the neighbouring hills. Theſe form a kind of amphitheatre, ſurrounding the fort and town, at the diſtance of from one to four miles. They are principally compoſed of a reddiſh ſchiſtus, which ſeems to contain a large proportion of iron. On the eaſtward of the town runs the ſmall river Soonrica. At the diſtance of 700 yards from the northern extremity of the fort is a conical hill, having on the top a remarkable ſtone building, which conſiſts of two high pillars, joined by an arch, and ſeeming to be of ancient workmanſhip. Beyond the river Soonrica is a handſome ſtone building, with a cupola covered with blue enamel, the tomb of Mahommed Ghous, a man celebrated for learning and ſanctity, in the time of the emperor Acbar. Within the incloſure which ſurrounds this monument, is a ſmall tomb, to the memory of Tan-Sein, a muſician of incomparable ſkill, who flouriſhed at the court of the ſame monarch. The tomb is overſhadowed by a tree, concerning which a ſuperſtitious notion prevails, that the chewing of the leaves will give an extraordinary melody to the voice. The diſtrict depending on this town, which includes the country of "Ghod," yields 22 lacks of rupees, 15 of which are paid into the treaſury, the remaining ſeven being allowed for the expence of collection. A conſiderable trade is carried on here in cloth from Chanderi, and in indigo. About ſeven coſs from hence, on the road to Nirwir, at the village of Beereih, is a mine of iron, which is worked to conſiderable advantage. The fort itſelf, from its great ſecurity, is made uſe of by Sindiah as a place of confinement for his ſtate priſoners, and the grand repoſitory of his artillery, ammunition, and military ſtores. N. lat. 26° 15'. E. long. 78° 28'. Aſiatic Reſearches, vol. vi.

GWENDRAETH RIVER, in Caermarthenſhire, in South Wales, is navigable only about two miles up from the Briſtol channel to Kidwelly town, where it is joined by the *Kidwelly*, or Miſs Keymer's coal canal (ſee our article CANAL). In 1806 Mr. Anthony Bower made a ſurvey of the lower port or eſtuary of this river, and, in 1809, Mr. William Smith alſo ſurveyed it, and propoſed a new cut for the current of the river (as has been done at Briſtol), and by means of embankments and a ſea-lock, to hold up 100 acres of floating dock or harbour, below the town of Kidwelly: his eſtimate of theſe works being 15,000*l*. Coals and limeſtone would be the principal articles of export from this harbour.

GWINNE, MATTHEW, in *Biography*, was born in London. In the year 1574 he was elected a ſcholar of St. John's college, Oxford, of which he afterwards became perpetual fellow. In 1582 he was made regent-maſter, agreeable to the cuſtom of the univerſity at that time, and was appointed to read lectures on muſic. After taking his degrees in arts, he entered upon medicine, and practiſed as a phyſician in Oxford and its neighbourhood. In 1588, he was choſen junior proctor; and in September 1592, was the firſt replier in a diſputation held at Oxford for the entertainment of queen Elizabeth. The following year he was created doctor of phyſic, and in 1595, by leave of the college, he attended ſir Henry Unton, ambaſſador from queen Elizabeth to the French court, in quality of his phyſician. On the foundation of Greſham college, in 1596, he was choſen its firſt profeſſor of phyſic, being one of the two nominated by the univerſity of Oxford, and having a further recommendation from lord chancellor Gerton. In the beginning of the year 1605, he was appointed phyſician to the Tower, and in December, the ſame year, was admitted a fellow of the college of phyſicians. After this he continued to practiſe in London with great reputation, both in the city and at court. He died, according to Wood, in 1627.

He publiſhed the following works: 1. "Epicedium in Obitum illuſtr. Herois, Henrici Comitis Derbienſis," Oxon. 1593.—2. "Nero, Tragædia nova," Lond. 1603.—3. "Orationes duæ, Londini habitæ in Ædibus Greſhamüs," 1605.—4. "Vertumnus, ſive Annus recurrens," 1607.—5. "Aurum non Aurum, &c."—6. "Verſes in Engliſh, French, and Italian."—7. "A Book of Travels."—8. "Letters concerning Chemical and Magical Secrets." Aikin's Biog. Mem. of Medicine.

GWYNEDD, one of the three principalities or kingdoms into which Wales was divided in the time of the heptarchy; the other two being Deheubarth and Mathravel, or Powys-land. Gwynedd, now North Wales, the country of the Ordovices, was divided into the four diſtricts of Mon, now Angleſey, Avuon, now Caernarvon, Meryonydd, now Merionethſhire, and of Berweddhylod, now Denbighſhire and Flintſhire. The chief reſidence of the princes of Gwynedd, or North Wales, was at Aberfraw, in the iſle of Angleſey. Each of theſe diſtricts or provinces in the three principalities of Wales, were ſubdivided into ſo many cantreves, and theſe again into ſo many commots; ſo as to make 51 cantreves, and 158 commots, in all Wales.

GY, a town of France, in the department of the Upper Saone, and chief place of a canton, in the diſtrict of Gray: nine miles E. of Gray. The place contains 2695, and the canton 12,886 inhabitants, on a territory of 247½ kiliometres, in 30 communes.

GYALGUR, called alſo *Gawile*, the principal fortreſs of Moodajee, the depoſitary of his treaſures and valuables, ſituated on a ſteep mountain, about 103 geographical miles to the W. by N. of Nagpour. See GAWILE.

GYARMATH, a town of Hungary; 20 miles E.S.E. of Levens.

GYAROS, or GYARUS, in *Ancient Geography*, a ſmall iſland of the Archipelago, and claſſed by Steph. Byz. among the Sporades, but rather belonging to the Cyclades; ſituated at

at a little diſtance from the coaſt of Attica, between Scyros to the S. W., and Andros to the N. W. The Romans in the time of the emperors had made it a place of exile: Thus Juvenal (Sat. 1. v. 73.)

"Aude aliquid brevibus Gyaris et carcere dignum,
Si vis eſſe aliquis: probitas laudatur et alget."

GYBING, in *Sea Language*, denotes the act of ſhifting any boom-ſail from one ſide of the maſt to the other.

GYEY, in *Geography*, a town of France, in the department of the Upper Marne; 12 miles N. W. of Langres.

GYGANEUM, in *Ancient Geography*, a town of Aſia, in the Colchide, on the coaſt of the Euxine ſea, near the mouth of the Iſis, and to the S.W. of it.

GYGAS, a promontory of Aſia, in the Troade, near Dardanus.

GYGES, in *Biography*, the miniſter and favourite of Candaules, king of Lydia, rebelled againſt his ſovereign, and having ſlain him, aſcended the throne in his ſtead. This event is placed about 718 B. C. He made war upon the people of Miletus and Smyrna, and conquered the whole diſtrict of Troas. He is ſaid to have reigned 38 years. This is the account given by Plutarch. Gyges, by other authors, is made the ſubject of a fable, which gives him the poſſeſſion of a magical ring that had the property of rendering the wearer inviſible. This fact is alluded to by many of the beſt claſſical authors. Herodotus gives another account of the ſubject. He tells us that Candaules expoſed the naked charms of his wife to Gyges, which, when ſhe diſcovered, ſo enraged her, that ſhe ſent for the miniſter, and gave him the choice of loſing his own life, or taking away that of his ſovereign, and occupying his place on the throne, and in her bed. He choſe the latter, ſtabbed the king in his ſleep, married the queen, and took poſſeſſion of the kingdom, over which he was permitted to reign in peace, after he had procured the ſanction of the Delphic oracle.

GYGOOGOO, in *Geography*, a village of Bootan, ſituated on the declivity of a hill, 12 miles from Buxadewar, conſiſting of five or ſix houſes, ſupported on bamboo props; the joiſts, beams, the matted walls, the connecting bands, and every part of the fabric, being made of bamboo, except the covering of the roof, which is compoſed of plantain-leaves doubled. The principal inhabitants are an old man, his daughter, and another female, who preſented captain Turner and his companions, in their embaſſy to Tibet, with vegetables, eggs, poultry, and the uſual offering of a pelong handkerchief, tea, and whiſky. Theſe people are ſtationed here by the Daeb Rajah, for the purpoſe of preſerving a quick and free communication with his poſſeſſions on the borders of Bengal, and of conveying, with expedition, letters and parcels to and from the capital. They cultivate a ſmall piece of ground, which furniſhes grain for their ſubſiſtence. Their herds of cows and ſwine ſeek their own food in the ſpontaneous paſture of the woods. Here were found two large peach-trees, ſome lime and orange-trees, and raſpberry-buſhes. At a ſmall diſtance flows the river Tehintchieu in a deep channel at the foot of the mountain. This river runs by Taſſiſudon, and being ſwelled by the united ſtreams of the Hatchieu, which paſſes near a place of the ſame name, and by the Patchieu, which takes its courſe near Paro, finds a paſſage between the mountains, from whence it is precipitated in tremendous cataracts, and ruſhing with rapidity between the high cliffs and vaſt ſtones that oppoſe its progreſs, deſcends at length into the valley a few miles E. of Buxadewar, and finally joins the Berhampooter. Turner's Tibet, p. 47.

GYKOW, a town of the duchy of Holſtein; ten miles W. of Lutkenborg.

GYLIPPUS, in *Biography*, a Lacedæmonian commander, ſon of Clearchus, was ſent, about the year B.C. 414, through the influence of Lyſander, to the relief of Syracuſe, when it was beſieged by the Athenians. He obtained a great victory over Nicias and Demoſthenes, and obliged them to ſurrender. He accompanied Lyſander in his expedition againſt Athens, and was preſent at the capture of that city. After the fall of Athens, he was entruſted with the money that had been taken in the plunder, which amounted to 1500 talents. His avarice cauſed him to violate his truſt by a fraud: he unſewed the bottom of the bags in which it was contained, and ſecreted about 300 talents. His theft was diſcovered, and to avoid the puniſhment due to his guilt, he fled from his country, and was obliged to live in exile the remainder of his days. By this act of meanneſs the glory of all his former actions was tarniſhed, and his name has been tranſmitted to poſterity with the infamy it deſerves.

GYLONGS, an order of religious perſons, who inhabit Taſſiſudon in Bootan; they aſſemble in their chapels three times a day for the performance of their devotion, morning, noon, and evening. At the earlieſt dawn of day they chant their oriſons to the ſound of numerous inſtruments; at 12 they meet again to perform their devotion, and cloſe the evening with their prayers. The gates of the palace are then ſhut, as well for the ſake of tranquillity and ſafety, as to prevent a violation of their rigid rules of chaſtity. Fifteen hundred gylongs are contained within the walls of the palace, and not a female lodges under the ſame roof. The religious, from their firſt introduction into the order, are bound by its laws to celibacy, and are interdicted, by the ſevereſt penalties, from all connection with the female ſex; though ſome very pretty women are employed in carrying water into the palace. Sedentary as is the life of theſe gylongs, they appear fairer in their complexions, and more athletic, than the reſt of their countrymen. Accuſtomed to ablution, they reſort to a ſmall iſland at a little diſtance for the purpoſe of bathing in the Tehin-tchieu. Turner's Tibet, p. 83.

GYLPUT, in our *Old Writers*, the name of a court held every three weeks in the liberty or hundred of Pathbew, in the county of Warwick. "Inquiſit. ad quod damn." 13 Edw. III. Blount.

GYLTWITE, a compenſation or amends for treſpaſſes, &c. "Mulcta pro tranſgreſſione." LL. Edg. regis, anno 964. Terms of Law.

GYMNANTHERA, in *Botany*, from γυμνος, *naked*, and ανθηρα, the *anther*; becauſe thoſe parts are deſtitute of the beard obſervable on the anthers of *Periploca*, a genus nearly related to this. Brown. Aſclep. 47. Prod. Nov. Holl. v. 1. 464.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ.

Eſſ. Ch. Corolla ſalver-ſhaped, with a crown of five awned leaves. Filaments diſtinct, inſerted into the mouth of the corolla; anthers prominent, beardleſs; maſſes of pollen granulated, four-fold, attaching themſelves to the dilated ſummits of the prominences of each ſtigma. Follicles cylindrical, ſmooth, widely divaricated. Seeds comoſe.

1. G. *nitida*. Native of the tropical region of New Holland. *Plant* ſhrubby, twining, ſmooth, milky. *Leaves* oppoſite, ſhining. *Flowers* greeniſh-white, beardleſs, on lateral, rather forked ſtalks. There are five notched ſcales, inſerted on the inſide of the ſinuſes of the calyx. *Brown.*

GYMNANTHES, from γυμνος, *naked*, and ανθος, *a flower*, Swartz. Prod. 95. Schreb. Gen. 656, is now reduced by its author to *Excoecaria*. His *G. ellipica* is *E. tinifolia*,

Fl.

Fl. Ind. Occ. 1119; and *G. lucida* is *E. lucida*, 1122. They are trees or ſhrubs with ſimple, ſmooth, ſhining leaves, and axillary catkins, growing in the ſouthern parts of Jamaica. See EXCOECARIA.

GYMNARTHRIDIA, in the *Hiſtory of Inſects*, a ſeries or claſs of inſects, which have ſoft and naked bodies furniſhed with limbs.

Theſe have been generally called *zoophytes*, a term expreſſing creatures partly of an animal and partly of a vegetable nature; but as it is now well known that there are none ſuch, it is proper that the term zoophyte ſhould no longer be retained.

Under this claſs are comprehended the limax, or the naked ſnail, the lernea, meduſa, aphrodita, amphitrite, &c.

GYMNASIA, in *Ancient Geography*, a town of Aſia, in the Colchide. Diod. Sic. l. 14.

GYMNASIARCH, GYMNASIARCHA, compounded of γυμνασιον, and αρχη, *government*, in *Antiquity*, the maſter or director of a gymnaſium.

The Greeks did not rank the gymnaſiarcha among the number of magiſtrates; though his office was of great conſideration, as having the care of all the youth, who were truſted to him to be formed to exerciſes of the body.

He had two principal officers under him, who were to aſſiſt him in the government of the gymnaſium; the firſt named *xyſtarcha*, and the ſecond *gymnaſta*. The former was maſter of the *athletæ*, and preſided over the wreſtling. (See ATHLETÆ.) The latter had the direction of all the other exerciſes, taking care they were performed in due time and manner, that they were not too ſevere, that the youth attempted nothing beyond their ſtrength, and that nothing were done that might be injurious to their health.

Theſe had ſeveral ſubaltern officers or ſervants under them, for the ſervice and inſtruction of the youth committed to them.

GYMNASIUM, a place fitted for the performing exerciſes of the body.

This word is γυμνασιον, formed of γυμνος, *naked*; becauſe they anciently put off their clothes, to practiſe with the more freedom.

Among the ancients, gymnaſium was a public edifice deſtined for exerciſe, and where people were taught, and regularly diſciplined under proper maſters.

If we may credit Solon in Lucian's Anacharſis, and Cicero, De Orat. lib. ii. the Greeks were the firſt who had gymnaſia; and among the Greeks, the Lacedæmonians; after them the Atheniians, from whom the Romans borrowed them.

There were three principal gymnaſiums at Athens; the academy, where Plato taught; the lyceum, noted for Ariſtotle's lectures; and the cynoſarges, allotted for the populace.

Vitruvius deſcribes the ſtructure and form of the ancient gymnaſia, lib. v. cap. 11. They were called gymnaſia, becauſe the champions performed *naked*; and palæſtræ, from *wreſtling*, which was one of the moſt uſual exerciſes there: the Romans ſometimes alſo called them *thermæ*, becauſe the baths and bagnios made a principal part of the building.

It appears that they did not perform their exerciſes quite naked, ſo early as the time of Homer, but always in drawers; which they did not lay aſide before the thirty-ſecond Olympiad. One Orſippus is ſaid to have been the firſt who introduced the practice: for having been worſted, by means of his drawers undoing and entangling him, he threw them quite aſide, and the reſt afterwards imitated him.

The gymnaſia conſiſted of ſeven members, or apartments. M. Burette, after Vitruvius, recites no leſs than twelve, viz. 1. The exterior *porticos*, where the philoſophers, rhetoricians, mathematicians, phyſicians, and other virtuoſi, read public lectures, and where they alſo diſputed and rehearſed their performances. 2. The *ephebeum*, where the youth aſſembled very early, to learn their exerciſes in private, without any ſpectators. 3. The *coryceum*, *apodyterion*, or *gymnaſterion*, a kind of wardrobe, where they ſtripped, either to bathe or exerciſe. 4. The *elæotheſium*, *alipterion*, or *unctuarium*, appointed for the unctions, which either preceded or followed the uſe of the bath, wreſtling, pancratia, &c. 5. The *coniſterium*, or *coniſtra*, in which they covered themſelves with ſand, or duſt, to dry up the oil, or ſweat. 6. The *palæſtra*, properly ſo called, where they practiſed wreſtling, the pugillate, pancratia, and divers other exerciſes. 7. The *ſphæriſterium*, or tennis-court, reſerved for exerciſes wherein they uſed balls. 8. Large unpaved alleys, which comprehended the ſpace between the porticos and the walls wherewith the edifice was ſurrounded. 9. The *xyſti*, which were porticos for the wreſtlers in winter, or bad weather. 10. Other *xyſtis*, or open alleys, allotted for ſummer and fine weather, ſome of which were quite open, and others planted with trees. 11. The *baths*, conſiſting of ſeveral different apartments. 12. The *ſtadium*, a large ſpace of a ſemicircular form, covered with ſand, and ſurrounded with ſeats for the ſpectators. For the adminiſtration of the gymnaſia, there were divers officers: the principal were, 1. The *gymnaſiarcha*, who was the director and ſuperintendent of the whole. 2. The *xyſtarcha*, who preſided in the xyſtus, or ſtadium. 3. The *gymnaſta*, or maſter of the exerciſes, who underſtood their different effects, and could accommodate them to the different complexions of the athletæ. 4. The *pædotriba*, whoſe buſineſs was mechanically to teach the exerciſes, without underſtanding their theory or uſe. Under theſe four officers were a number of ſubalterns, whoſe names diſtinguiſhed their different functions.

As to the kinds of exerciſes practiſed in the gymnaſia, they may be reduced to two general claſſes, as they depend either on the action of the body alone, or as they require external agents or inſtruments. The former are chiefly of two kinds, *orcheſtice* and *palæſtrice*.

The *orcheſtice* comprehended, 1. *Dancing*. 2. *Cubiſtice*, or the art of tumbling. 3. *Sphæriſtice*, or tennis, including all the exerciſes with pilæ, or balls.

The *palæſtrice* compriſed all exerciſes under the denomination *palæſtra*; as *wreſtling*, *boxing*, *pancratia*, *hoplomachia*, *running*, *leaping*, *throwing the diſcus*, the *exerciſe of the javelin*, and that of the *hoop*, denominated by the Greeks τροχος, which conſiſted in rolling an iron hoop five or ſix feet in diameter, beſet with iron rings, the noiſe of which apprizing the people to give way, afforded them alſo an amuſement. Both ſtrength and ſkill were requiſite in directing this hoop, which was to be driven with an iron rod.

To theſe muſt alſo be added the exerciſes belonging to the medicinal gymnaſtics, as, 1. *Walking*. 2. *Vociferation*, or ſhouting. 3. *Holding one's breath*.

The bodily exerciſes, which depend on external agents, may be reduced to *mounting* the horſe, *riding* in a chaiſe, or other wheeled vehicle: *rocking* in beds or cradles, and ſometimes *ſwinging*: to which may be added, the art of *ſwimming*. Hoffman enumerates no leſs than fifty-five ſorts of gymnaſtic exerciſes.

GYMNASTES, Γυμναστης, among the *Ancients*, an officer in the ancient *gymnaſium*, next in authority to the *gymnaſiarch* and *xyſtarch*.

GYMNASTERIUM, Γυμναστηριον. See GYMNASIUM.

GYMNASTICS, GYMNASTICE, or the GYMNASTIC *Art*,

Art, denotes the art of performing exercifes of the body, whether for defence, health, or diverfion.

The gymnaftic art is divided into three fpecies or branches; *military*, *medicinal*, and *athletic*, or *fportive*.

Several modern writers have treated of this art; as Mercurialis, De Arte Gymnaftica: Faber, in Agoniftic. Joubert, de Gymnafiis; Cagnatus, De Sanit. Tuend. Voffius, De Quatuor Artib. Popular. Mearfius, De Orcheftra; Fuller, in Medicina Gymnaftica; and M. Burette, in feveral differtations on the ancient Dancing, Spheriftics, Athletics, Wreftling, Pugillate, Difcus, &c.

M. Burette has given the hiftory of gymnaftics in the Memoirs of the Royal Academy of Inferiptions. According to him, this art is coeval with the world. In reality, we can hardly fuppofe mankind to have ever been without fome fort of exercifes of the body, which the defence of their perfons, the preservation of health, and even recreation and mirth, would neceffarily lead them to. See EXERCISE.

On the firft eftablifhment of fociety, men, being appriſed of the neceffity of military exercifes, for repelling the infults of their neighbours, inftituted games, (fee GAMES,) and propofed prizes, to animate their youth to combats of divers kinds. And as running, leaping, ftrength and dexterity of arm in throwing the javelin, driving a ball, or toffing a quoit, together with wreftling, &c. were exercifes fuited to the manner of fighting in thofe days, fo the youth vied to excel in them, in the prefence of the aged, who fat as their judges, and difpenfed prizes to the conquerors; till what was originally only amufement, became, at length, a matter of fuch importance, as to intereft famous cities, and entire nations, in its practice.

Hence arofe an emulation and eagernefs to excel, in hopes, one day, of being proclaimed and crowned conquerors in the public games, which was the higheft honour a mortal could arrive at: nay, they went fo far as to imagine, that even gods and demi-gods were not infenfible of what men were fo captivated with; and, in conſequence hereof, to introduce the greateft part of thefe exercifes into their religious ceremonies, the worfhip of their gods, and the funeral honours done to the manes of the dead.

Though it be hard to determine the precife epocha of the gymnaftic art, yet it appears, from feveral paffages in Homer, and particularly the twenty-third book of the Iliad, where he defcribes the games celebrated at the funeral of Patroclus, that it was not unknown at the time of the Trojan war. From that defcription, which is the earlieft monument now extant of the Grecian gymnaftics, it appears, that they had chariot-races, boxing, wreftling, foot-races, gladiators, throwing the difcus, drawing the bow, and hurling the javelin; and it fhould feem, from the particular account Homer gives of thefe exercifes, that even then the gymnaftic art wanted little of perfection: fo that when Galen fays there was no gymnaftic art in Homer's days, and that it began to appear no earlier than Plato, he is to be underftood of the medicinal gymnaftics only. This laft, indeed, had its rife later: becaufe, while men continued fober and laborious, they had no occafion for it; but when luxury and idlenefs had reduced them to the fad neceffity of applying to phyficians, thefe, who had found that nothing contributed fo much to the preservation and re-eftablifhment of health as exercifes, proportioned to the different complexions, ages, and fexes, did not fail to refer them to the practice of gymnaftics.

According to Plato, one Herodicus, prior a little time to Hippocrates, was the firft who introduced this art into phyfic; and his fucceffors, convinced by experience of its ufefulnefs, applied themfelves in earneft to improve it.

Hippocrates, in his book of Regimen, has given inftances of it, where he treats of exercife in general, and of the particular effects of walking, with regard to health; alfo of the different forts of races, either on foot or horfeback; leaping, wreftling, the exercife of the fufpended ball, called *corycus*, chironomy, unctions, frictions, rolling in the fand, &c.

But as phyficians did not adopt all the exercifes of the gymnaftic art in their practice, it came divided between them and the maſters of martial and athletic exercifes, who kept fchools, the number of which was greatly increafed in Greece.

At length the Romans alfo caught the fame taſte; and adopting the military and athletic exercifes of the Greeks, they improved them and advanced them to the utmoft pitch of magnificence, not to fay extravagance. But the declenfion of the empire involved the arts in its ruin, and, among others, gymnaftics and medicine; which laft unhappily then relinquifhed the title it had to the former, and has neglected to refume it ever fince.

The *five* gymnaftic exercifes, fo much celebrated by all the writers of antiquity, and fo accurately deſcribed by Homer, Pindar, Sophocles, and Paufanias, began, 1. With the foot race, which is fuppofed to have been the moft ancient, and which always retained the prerogative of diftinguifhing the olympiads by the name of the victorious racer. At firft this exercife conſiſted in running naked from one end of the ftadium to the other. The courfe was afterwards doubled, and at length the competitors were required to pafs the goal three, fix, and even twelve times, before they could be entitled to the prize. Motives of utility introduced the race of men loaded with heavy armour; which rendered this exercife a conteft of ftrength as well as of fwiftneſs. 2. The fecond trial of agility conſiſted in leaping, the competitors endeavouring to furpafs each other in the length, without regard to the height of their leaps. They carried in their hands weights of lead, through the perforations of which their fingers paſſed, as through the handle of a fhield, and by thefe they poiſed, and impelled forwards their bodies. The perfection attained in this exercife muſt have far exceeded the experience of modern times, if we may believe what Paufanias fays of Phaulus of Crotona, that he leaped 52 feet. 3. The wreftling of the ancients required equal ftrength and agility. It was chiefly remarkable on account of the oil and fand with which they rubbed their bodies, in order to fupple their joints, to prevent exceffive perſpiration, and to elude the grafp of their antagoniſts. The wreftlers were matched by lot, and the prize was adjuſted to him who had thrice thrown his adverfary on the ground. 4. The following exercifes tried chiefly the ſtrength of the arms; the firſt conſiſted in throwing a huge maſs of poliſhed iron, brafs, or ſtone, of a circular form, reſembling a ſhield, but without handle or thong. It was called the diſk, and thrown under the hand as the quoit is in England. The object of the competitors was to furpaſs each other in the length of the caſt. Akin to this was the art of darting the javelin, which, as that weapon was darted at a mark, required ſteadineſs of eye as well as dexterity of hand. 5. The laſt of the gymnaſtic exercifes, both in order and eſtimation, was that of boxing. It was ſometimes performed by the naked fiſt, and ſometimes with the formidable cæſtus, compoſed of raw hides lined with metal. Before the victory could be decided, it was neceſſary, from the nature of that exercife, that one of the combatants ſhould acknowledge his defeat; a condition which ſeemed ſo inconſiſtent with the obſtinacy of Grecian valour, that few ventured to contend in this dangerous amuſement. The laws of Sparta abſolutely

abſolutely prohibited her citizens from ever engaging in it, becauſe a Spartan was taught to diſdain ſaving his life by yielding to an opponent. Another reaſon, no leſs remarkable, tended ſtill more to degrade the exerciſe of boxing. Beſides ſtrength and agility, the ſucceſs of the boxer, it was thought, depended on a certain ponderous fleſhineſs of arm, which unfitted him for engaging in any other conteſt. The regimen required for keeping up his corpulency, ſo neceſſary for the defence of his bones againſt the weight of blows, was altogether incompatible with the life of a ſoldier; a life of hardſhip and inequality, and continually expoſed to the want of reſt, of proviſions, and of ſleep. Theſe were the *five* gymnaſtic exerciſes, in which the Grecian youth were trained with ſo much care, and to which they applied with ſo much emulation. But beſides theſe ſimple ſports, there were two others formed of their various combination. The "Pancratium," which conſiſted of wreſtling and boxing; and the "Pentathlon," in which all the five were united; and to excel in ſuch complicated exerciſes required an education and mode of living not neceſſary to be obſerved by thoſe who contended in the ſimple feats of ſtrength and agility, and which was ſcarcely compatible with the ſtudy of any other than the athletic profeſſion. See each of the articles above-mentioned.

GYMNEMA, in *Botany*, from γυμνος, *naked*, and νημα, a *thread* or *ſtamen*; the ſtamens being deſtitute of the leafy crown, uſual in the tribe to which it belongs. Brown Aſclep. 22. Prod. Nov. Holl. v. 1. 461.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ.

Eſſ. Ch. Corolla ſomewhat pitcher-ſhaped, five-cleft; its orifice moſtly crowned with five little ſcales or teeth, inſerted into its ſinuſes. Crown of the ſtamens wanting. Anthers terminated by a membrane. Maſſes of pollen erect, attached by their baſe. Follicles ſlender, ſmooth. Seeds comoſe.

The habit is ſhrubby, and generally twining. Leaves oppoſite, membranous, flat. Umbels cymoſe, between the leaf-ſtalks, not properly axillary.

Of this genus Mr. Brown has aſcertained four ſpecies.

1. G. *geminatum*. Mouth of the corolla crowned; tube ſlightly downy within. Umbels in pairs; their ſtalks ſhorter than the footſtalks. Leaves ovate, ſmoothiſh. Branches downy. Stem twining.—Native of the tropical part of New Holland.

2. G. *trinerve*. Mouth of the corolla naked. Umbels ſeſſile. Leaves oblong-lanceolate, three-nerved, downy. Stem erect.—Native of the ſame country.

The other two, of which we have no ſpecimens, nor have proper ſpecific differences, as contraſted with the above, been given, are the following.

3. G. *lactiferum*. (Aſclepias lactifera; Linn. Sp. Pl. 314. A. n. 111; Fl. Zeyl. 46.)—"Leaves ovate, pointed. Stem erect."—Native of Ceylon. *Herb. Hermann.* Very much like *Aſclepias Vincetoxicum*, except that the leaves are leſs heart-ſhaped. The umbels are oppoſite, ſcarcely longer than the footſtalks. *Linn.*

4. G. *ſylveſtre*. (Periploca ſylveſtris; Willd. Phytogr. faſc. 1. 7. t. 5 f. 3.)—"Leaves ovate, reticulated; downy beneath. Stem twining, downy. Umbels ſolitary, their ſtalks as long as thoſe of the leaves."—Native of Ceylon.

GYMNIA, in *Zoology*, a claſs of animalcules, containing ſuch as have neither tail, nor any viſible limbs. See ANIMALCULE.

GYMNIAS, in *Geography*, a large, rich, and well-peopled town of Aſia, in Armenia.

GYMNIC, GYMNICUS, ſomething belonging to the exerciſes of the body.

Gymnic games, *ludi gymnici*, are thoſe wherein the body is exerciſed; ſuch are wreſtling, running, dancing, the uſe of the lance, quoit-playing, &c.

Theſe made the chief diverſions of the Olympic, Nemean, Pythian, and Iſthmian ſolemnities; being called by the Greeks Πεντάθλον, and the Latins *quinquertium*. See PENTATHLON.

GYMNOCARPI, in *Botany*, from γυμνος, *naked*; and καρπος, *fruit*, the ſecond of the two great ſections in Perſoon's ſyſtem of *Fungi*, and by far the moſt important and numerous, as comprehending, amongſt others, the moſt extenſive genus *Agaricus*. Its definition is, "*Fungi* of a fleſhy texture, bearing their ſeeds (ſparingly) in an open receptacle, called the *Hymenium*." It conſiſts of three ſub-diviſions; improperly termed orders, as the whole tribe of *Fungi* itſelf is but an order of the great claſs *Cryptogamia*.

1. *Lytothecii*. The fructifying membrane, or *hymenium*, finally reſolving itſelf into a jelly, as in *Clathrus* and *Phallus*.

2. *Hymenothecii*. *Hymenium* membranous, permanent, powdery with the minute ſeeds, as in *Agaricus* and its allies; alſo *Boletus*, *Clavaria*, *Helvella*, &c.

3. *Næmatothecii*. Fungi of a downy or fibrous habit, as *Dematium*, *Erineum*, *Racodium*, &c. This laſt diviſion is rather a ſweeping one, and comprehends various obſcure productions, whoſe natural orders are by no means agreed on. Some botaniſts call them *Byſſi*, others *Confervæ*, or *Lichenes*, according as they themſelves have choſen one tribe or another for their particular ſtudy.

GYMNOCLADUS, from γυμνος, *naked*, and κλαδος, a *ſlender branch*; ſo named by Lamarck, in alluſion to the naked, and ſeemingly dead, appearance of its branches in winter, which has induced the French ſettlers in Canada to call it *Chicot*, or Stump-tree. Lamarck. Dict. v. 1. 733. Illuſtr. t. 823. Schreb. 696. Juſſ. 346. (Bonduc; Duham. Arb. v. 1. 107. t. 42.)—Claſs and order, *Dioecia Decandria*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of one leaf, funnel-ſhaped; tube oblong, with 10 furrows, contracted at the mouth; limb in five deep, linear, acute, nearly equal, ſpreading ſegments, rather ſhorter than the tube. *Cor.* Petals five, lanceolate, bluntiſh, nearly equal, ſpreading, rather longer than the ſegments of the calyx, inſerted into the mouth of its tube. *Stam.* Filaments 10, thread-ſhaped, inſerted into the upper part of the tube, five of them rather the longeſt, all of them much ſhorter than the corolla; anthers ovate, erect. *Piſt.* ſcarcely any.

Female, *Cal.* and *Cor.* like the male. *Piſt.* Germen ſuperior, oblong; ſtyle ſhort; ſtigma obtuſe. *Peric. Legume* oblong, thick, pulpy, of ſeveral cells, divided by tranſverſe partitions. *Seeds* ſolitary in each cell, roundiſh, very hard.

Eſſ. Ch. Male. *Calyx* tubular, five-cleft. Petals five.—Female. Calyx and Corolla like the male. Stigma obtuſe. Legume of ſeveral cells. Seeds ſolitary.

1. G. *canadenſis*. Michaux. Bor. Am. v. 2. 241. t. 51. (Guilandina dioica; Linn. Sp. Pl. 546. Ait. Hort. Kew. v. 2. 56.)—A native of Canada, hardy in our gardens, where it has long been cultivated, though we have never heard of its bloſſoming. This is the only certain ſpecies, the *G. arabica* of Lamarck belonging to the genus *Hyperanthera*, along with the *Guilandina Moringa* of Linnæus. The *Gymnocladus*, or Hardy Bonduc, is a ſtraight handſome *tree*, with a fine leafy top in ſummer, but thin and unſightly when the foliage is gone. The *leaves* are very large,

large, doubly pinnate, their leaflets ovate, ſlightly ſtalked, an inch and half long, acute, entire, veiny, ſlightly downy. *Flowers* in terminal, denſe, rather compound bunches, whitiſh, minutely downy. *Legumes* four or five inches long, thick and fleſhy. *Seeds* very hard, requiring much moiſture, and a hot-bed, to make them vegetate. The tree, according to Duhamel, loves a dry ſoil, and will not grow in marſhy places. If cut down or removed, ſuch parts of the roots as happen to remain produce abundance of young plants.

GYMNOPÆDIA, a kind of dance, eſtabliſhed by Lycurgus, and in uſe among the ancient Lacedæmonians; performed, during their ſacrifices, by young perſons, who danced naked, ſinging at the ſame time a hymn in honour of Apollo.

The word is alſo written *gymnopædice*; it is compounded of γυμνος, *naked*, and παις, *child*.

Terpander is recorded as the inventor of the gymnopædia. Athenæus deſcribes it as a Bacchic dance, performed by youths ſtripped quite naked, with certain interrupted though agreeable motions and geſtures of the body; the arms and legs being flouriſhed and directed after a peculiar manner, repreſenting a ſort of real wreſtling.

GYMNOPODIA, among the *Ancients*, a kind of ſhoes which diſcovered the naked feet. They were worn by the Grecian women, who were very fond of them.

GYMNOPUS, in *Botany*, from γυμνος, *naked*, and πους, the *foot*, the third and largeſt ſection of the genus *Agaricus* in Perſoon, conſiſting of one hundred and thirty-ſeven ſpecies, which have a central ſtalk, deſtitute of a veil or ring.

GYMNOPYRIS, in *Natural Hiſtory*, the name of a genus of foſſils, the characters of which are theſe: they are of the claſs of the *pyritæ*, and are compound, inflammable, metallic bodies, found in detached maſſes, of no determinately angular figure; of a ſimple internal ſtructure, not ſtriated; and are naked, or not covered with any inveſtient coat or cruſt, in which they differ from the pyriplaces.

Of this genus there are only two known ſpecies.

GYMNOSOPHISTS, a claſs of Indian philoſophers, famous in antiquity; ſo denominated from their going barefoot. The word is formed of the Greek γυμνοσοφιστης, q. d. a ſophiſt or philoſopher who goes naked.

This name was given to the Indian philoſophers, whom the exceſſive heat of the country obliged to go naked; as that of *Peripatetics* was given to thoſe who philoſophiſed walking.

Laertius, Vives, &c. will not have Gymnoſophiſt to have been the name of any particular ſect, but a common name of all the philoſophers in the Indies; and hence they divide them into Brachmans and Germani.

Among the Germani, called alſo by Porphyry *Samanæi*, and by Clemens Alexand. *Sarmanæ*, ſome were called *Hylobii*, by Clemens Alexand. *Alobii*, as inhabiting the woods; which laſt ſeem to come neareſt to the notion of Gymnoſophiſts. Clemens relates, that theſe Alobii neither inhabit cities nor towns, are clothed moſtly with the leaves of trees, eat acorns and berries, and drink water out of their hands, abſtaining from marriage and procreation.

The Gymnoſophiſts believed the immortality and tranſmigration of the ſoul: they placed the chief happineſs of man in a contempt of the goods of fortune and the pleaſures of ſenſe, and gloried in having given faithful and diſintereſted counſels to princes and magiſtrates. It is ſaid, that when they became old and infirm, they threw themſelves into a pile of burning wood, in order to prevent the miſeries of an advanced age. One of them, named Calamus, thus burnt himſelf in the preſence of Alexander the Great.

The Indian Gymnoſophiſts were more diſtinguiſhed by ſeverity of manners than by the cultivation of ſcience, and they ſeem to have more reſembled modern monks than ancient philoſophers. Some of them, however, allowed themſelves a greater latitude of manners than others; but their general characteriſtics were rigid abſtinence, indolence, and the pride of independence. Of their high ſpirit Strabo relates the following inſtance: when Oneſicritus was commiſſioned by Alexander to invite a body of theſe philoſophers to viſit him, they refuſed to go, ſaying, that if Alexander had any buſineſs with the Brachmans, he might come to them. Their abſtinence and hardy endurance made a ſtrong impreſſion on the minds of the multitude, and gave them great influence in an age of ignorance and ſuperſtition; more eſpecially, as they arrogated to themſelves the whole buſineſs of foretelling future events, and appropriated to themſelves the regulation of religious concerns. Arrian Exp. Alex. l. vii.

Apuleius, Forid. lib. i. deſcribes the Gymnoſophiſts thus; "They are all devoted to the ſtudy of wiſdom, both the elder maſters and the younger pupils; and what to me appears the moſt amiable thing in their character is, that they have an averſion to idleneſs and indolence: accordingly, as ſoon as the table is ſpread, before a bit of victuals be brought, the youths are all called together from their ſeveral places and offices, and the maſters examine them what good they have done ſince the ſun-riſe; here one relates ſomething he has diſcovered by meditation; another has learned ſomething by demonſtration; and as for thoſe who have nothing to alledge why they ſhould dine, they are turned out to work faſting."

The great leader of the Gymnoſophiſts, according to Jerom, was one Buddas, called by Clemens Butta, who is ranked by Suidas among the Brachmans. That laſt author makes Buddas, the preceptor of Manes the Perſian, the founder of the Gymnoſophiſts.

Ptolemy aſſigns to the Gymnoſophiſts a ſituation in the north-eaſtern part of India, between the Hyphaſis and the Ganges; whereas the Brachmans, or Brahmins, a branch of the Gymnoſophiſts, were fixed by the ſame geographer in the ſouthern part of this region, between the Solenus and the Chaberus, two rivers not far from the ſea-coaſt, and by theſe different ſituations, he ſeems to have conſidered the latter as ſeparate and diſtinct from the former.

There were likewiſe African Gymnoſophiſts, who dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either of houſe or cell. Theſe did not form themſelves into ſocieties, like thoſe of India; but each had his private retirement, where he ſtudied and performed his devotions by himſelf. If any perſon had killed another by chance, he applied to theſe ſages for abſolution, and ſubmitted to whatever penances they enjoined. They pretended to an extraordinary frugality, and lived only upon the fruits of the earth. Lucian aſcribes to theſe philoſophers ſeveral new diſcoveries in aſtronomy. They performed the ſacred functions after the manner of the Egyptian prieſts; had diſtinct colleges and claſſes of diſciples, and taught their dogmas in obſcure and mythological language. They were remarkable for their contempt of death.

The morality of the Ethiopians, it is ſaid by Laertius, conſiſted in worſhipping the gods, doing no evil, exerciſing fortitude, and deſpiſing death. See ETHIOPIA.

GYMNOSPERMIA, in *Botany*, from γυμνος, *naked*, and σπερμα, *ſeed*, the firſt order of the Linnæan 14th claſs;

Didynamia, conſiſting of ſuch plants of that claſs as have naked ſeeds, in which it differs from the ſecond order, or *Angioſpermia*. (See DIDYNAMIA and ANGIOSPERMIA.) The ſeeds are, except in two or three genera, which have ſolitary ſeeds, always four to each flower, and the permanent calyx performs the office of a ſeed-veſſel. Some writers contend that there is no ſuch thing in nature as a naked ſeed, which is perfectly true, inaſmuch as the internal eſſential parts of a ſeed muſt have one or more integuments, to contain their originally almoſt fluid ſubſtance, while it aſſumes a determinate configuration and ſtructure, and to afford it ſubſequent protection. Such integuments make an eſſential part of the ſeed itſelf, whether it be lodged in a pericarp or not, and ſuch only are found in the plants of the order in queſtion, which is nearly a natural one, including the labiate flowers, except thoſe which, having but two ſtamens inſtead of four, are neceſſarily referred to the claſs *Diandria*. This exception, however, conſtitutes a great objection to the Linnæan ſyſtem in the minds of thoſe who conſider it otherwiſe than an artificial one, and in ſome degree interferes with its convenience and accuracy; for *Verbena*, a natural genus, has ſome ſpecies with four unequal ſtamens, which refer it to *Didynamia* among its allies, while others have but two. Hence authors, according to their having examined more of the one or of the other, differ about its claſs.

All the plants, however, which properly belong to the *Didynamia Gymnoſpermia*, form a natural aſſemblage without any exception. Their qualities are aromatic or bitter, and there is no noxious herb amongſt them. The calyx is in ſome genera two-lipped; in others its ſegments are nearly equal; in both caſes they are, more or leſs diſtinctly, five in number. Moſt of the genera of this order, though ſo natural an one, are themſelves very naturally diſtinguiſhed by habit, and ſome one or more eſſential characters. See AJUGA, LAMIUM, MENTHA, &c.

GYMNOSTACHYA, from γυμνος, *naked*, and σταχυς, a *ſpike*. Brown. Prod. Nov. Holl. v. 1. 337. We preſume to alter the termination, becauſe *Stachys* being an eſtabliſhed genus, *Gymnoſtachys* is exceptionable.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Piperitæ*, Linn. *Aroïdeæ*, Juſſ.

Eſſ. Ch. Spatha minute, keeled. Spadix cylindrical, entirely covered with flowers. Perianth in four deep ſegments. Stamens inſerted into its baſe. Germen with one pendulous ſeed. Stigma ſeſſile, co-arctated. Berry naked. Seed with an albumen. Embryo inverſe.

1. G. *anceps*. Native of the country near Port Jackſon, New South Wales. *Herb* perennial, of a peculiar habit. *Root* with cluſtered ſpindle-ſhaped knobs. *Leaves* radical, graſſy, elongated, ribbed. *Stalk* two-edged, naked. *Spadixes* cluſtered in alternate order towards the top of the ſtalk, ſlender, ſtalked, each accompanied by a *bractea*, or *ſpatha*, (which is keeled, acute, ſcarcely longer than the partial ſtalk,) and very denſely covered all over with ſeſſile naked *flowers*. *Berry* blue. *Mr. Brown.*

GYMNOSTOMUM, from γυμνος, *naked*, and στομα, the *mouth*. Beardleſs-moſs. Hedw. Fund. v. 2. 87. t. 7. f. 31. Schreb. 758. Sm. Fl. Brit. 1158. Swartz. Muſc. Suec. 19. Turn. Muſc. Hib. 7. (Hedwigia; Ehrh. Crypt. 192. Hedw. Fund. v. 2. Anictangium; Hedw. Sp. Muſc. 40. Bryi ſpecies variæ; Linn. Hudſ.)—Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Capſule without a fringe. Lid deciduous. Veil ſeparating entire from the baſe.

The orifice of the capſule, from which the lid ſpontaneouſly ſeparates entirely, being deſtitute of all fringe or teeth, ſufficiently characterizes the preſent genus. (See FRINGE of *Moſſes*.) The capſule moreover is ſtalked as in all other moſſes except *Sphagnum*, the only one beſides that has a naked mouth; but which is extremely peculiar for having the capſule not elevated above the original baſe of the flower, as obſerved by Weber and Mohr, and a veil that never ſeparates from that baſe, but ſplits all round as the fruit ſwells. Its anthers moreover are each bound with a vertical jointed ring; in all which characters it differs from *Gymnoſtomum*. The original *Hedwigia* of Ehrhart is diſtinguiſhed from *Gymnoſtomum* by having lateral, not terminal, female flowers, a diſtinction which Swartz and ſeveral other botaniſts have conſidered as not ſufficient in this caſe to form a generic difference, though the only one between *Bryum* and *Hypnum*. Swartz therefore uniting this *Hedwigia* to the genus before us, eſtabliſhed another; ſee HEDWIGIA. His deciſion is now reverſed on the continent, and, we are inclined to think, not without reaſon. But the *Hedwigia* of Swartz could not be aboliſhed, and therefore that of Ehrhart has received a new appellation, *Anictangium*, from ανοικτος, *open* or *ſpreading*, and αγγειον a *veſſel* or *capſule*, alluding not only to the nakedneſs of the mouth, but to its being uſually dilated alſo. See examples of this latter genus in *Engliſh Botany*, t. 1179, 2216 and 2237.

The general habit of *Gymnoſtomum*, properly ſo called, is either a very ſhort ſimple *ſtem*, with broadiſh *leaves*, and an annual *root*, the *fruitſtalk* being ſolitary and terminal, and the *capſule* ſwelling upward; or the *roots* and *ſtems* are perennial, the latter branched and forming level-topped tufts. In theſe the *leaves* are much narrower and more copious, and the *capſules* ſmaller.

Of the former tribe are G. *truncatulum*, Engl. Bot. t. 1975, a very minute plant, common on banks in the ſpring; G. *intermedium*, t. 1976; G. *obtuſum*, t. 1407; G. *ovatum*, t. 1889; the more rare G. *Heimii*, t. 1951; and G. *faſciculare*, t. 1245, which is the real *Bryum Ægypti* of Haſſelquiſt, found abundantly by him on the walls of Jeruſalem, and therefore preſumed, not improbably, to be what Solomon meant by the "Hyſſop that ſpringeth out of the wall;" hyſſop appearing to be a kind of comprehenſive word for herbaceous plants, and the minuteneſs of this forming a ſtriking contraſt to the cedar of Lebanon. G. *pyriforme*, t. 413, a frequent and conſpicuous moſs, is of this family.

Of the ſecond tribe are G. *viridiſſimum*, Engl. Bot. t. 1583; G. *æruginoſum*, t. 2200; G. *luteolum*, t. 2201; G. *curviroſtrum*, t. 2214, a ſingularly miſtaken and confuſed ſpecies, even with the greateſt muſcologiſts; and G. *ſtelligerum*, t. 2202.

Some very pretty and curious ſpecies which do not exactly come under the above heads are,

G. *oſmundaceum*, t. 2213. (G. pennatum; Hedw. Crypt. v. 1. 77. t. 29. Mnium oſmundaceum; Dickſ. Crypt. faſc. 1. 3. t. 1. f. 4. H. Sicc. faſc. 12. 21.) To this Ehrhart, thinking it a good genus of itſelf, gave the name *Dickſonia puſilla*, in his Crypt. n. 65. It is one of the moſt uncommon of plants, being found with us in Devonſhire only, in the road from Zele to South Tawton church, four miles from Okehampton, by the Rev. Mr. Newberry; but occurs in ſome parts of Germany. Its beauty is equal to its ſcarcity, the *ſtems* being elegantly pinnate, with two-ranked *leaves*, like a minute fern. The *flowers* are terminal, and dioecious. A great peculiarity having been obſerved in the *lid*, which is flat, tranſparent, and ſeparable into many parts, as if cut, Mohr has reſtored this moſs to the rank of a genus, by the name of *Schizoſtega*, for ſo doubtleſs it ought

to

to be, from σχιζω, to *cut* or *ſplit*, and στεγη, a *cover*, though in his Index Muſei he has printed it *Schiſtoſtega!*

G. *Griffithianum*, t. 1938. (Bryum Griffithianum; Dicks. Crypt. faſc. 4. 8. t. 10. f. 10.)—Found on the eaſt ſide of Snowdon, near the ſummit, by Mr. Griffith, and on Ben Lawers by Mr. W. J. Hooker. This ſpecies, unknown out of Britain, is extremely peculiar for its ſucculent habit, and ſpatulate, reticulated, thick *leaves*. The *fruitſtalk* is thick and ſucculent. *Veil* curiouſly reticulated, as in the genus *Hookeria*.

G. *Donnianum*, t. 1582, found on a rock in Perthſhire by Mr. George Don, is one of the ſmalleſt of plants, and remarkable for having ſlender briſtle-ſhaped *leaves*, with a ſtemleſs habit, and probably an annual *root*. The minute *capſule* is ſingularly neat, as if turned out of box-wood, cup-ſhaped when the taper lid is fallen, and remarkable for the projecting central column, which, as far as we have obſerved, is a ſure indication of a genuine *Gymnoſtomum*.

G. *Davallianum*, found only by the late Mr. Davall near Orbe in Switzerland, and by no perſon elſewhere, is not quite ſo minute as the laſt, and differs from it in having lanceolate *leaves*, and a hemiſpherical *lid*.

G. *trichodes* of Mohr, a German moſs, has the habit and ſmall ſize of the two laſt, but the *capſule* is ſtriated and more oblong.

G. *japonicum*, with ſeveral other pretty exotic ſpecies, are figured in the earlieſt plates of Hedwig's *Species Muſcorum*, and in the following ones ſome ſpecies of *Anictangium*. Of the latter however *A. bulboſum*, t. 6. f. 1—5, is a miſtake, of which we ſhall ſpeak under the article HOOKERIA.

GYMNOSTYLES, ſo named by Richard and Juſſieu, from γυμνος, *naked*, and στυλος, or στυλις, the *ſtyle*, becauſe of the long, permanent, naked ſtyle, ſerving to form a ſort of awn to the ſeed, and belonging to florets which have no corolla. Juſſ. in Ann. du Muſ. d'Hiſt. Nat. v. 4. 258.—Claſs and order, *Syngeneſia Polygamia-neceſſaria*. Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Calyx* rounded, ſimple, of numerous, linear-oblong, equal ſcales, in a ſingle row. *Cor.* compound, diſcoid. Male florets in the centre, few, tubular, with three or four equal, ſpreading teeth. *Stam.* Filaments three or four, very ſhort; anthers united into a tube. *Piſt.* Germen very ſlender, thread-ſhaped, abortive; ſtyle one, rather exceeding the ſtamens; ſtigma capitate, imperfect. Female florets in the circumference, numerous, quite deſtitute of corolla and ſtamens. *Piſt.* Germen wedge-ſhaped; ſtyle awl-ſhaped, permanent, naked above; ſtigma acute, notched. *Peric.* none, except the permanent calyx. *Seeds* ſolitary, wedge-ſhaped, compreſſed, convex on one ſide, concave on the other, dilated, crenate, toothed or lobed at the edges, more or leſs hairy at the top, and crowned with the rigid permanent ſtyle. *Recept.* naked, convex, dotted.

Eſſ. Ch. Receptacle naked. Seeds toothed at the margin, crowned with the permanent ſtyle. Calyx of a ſimple row of numerous ſcales. Florets of the radius numerous, without any corolla.

Obſ. This genus ſhould be placed in the Linnæan ſyſtem next to *Hippia*, from which it is very diſtinct, having no corolla to its marginal or female florets, and the ſeeds being tipped with the long hardened ſtyle. The long hair crowning the germen in two ſpecies, and of which there are traces about the baſe of the ſtyle in the third, is peculiar, and as Juſſieu well obſerves, not a real *pappus* or feed-down.

Three ſpecies are deſcribed by the learned author juſt named, all of them in our poſſeſſion.

1. G. *anthemifolia*. Juſſ. Ann. du Muſ. v. 4. 262. t. 61. f. 1.—Leaves doubly pinnatifid. Flowers radical. Seed rounded at the top, corrugated on the concave ſide.—Sent to Linnæus from Mexico by the celebrated Mutis. It has alſo been found in New Holland, and introduced to the gardens of Europe, where it merits preſervation for its curioſity, though ſcarcely for its beauty. The *root* is fibrous and apparently annual, producing a tuft of ſhort, quite proſtrate, leafy, downy *ſtems*, ſpreading every way cloſe to the ground, but ſcarcely creeping. *Leaves* numerous, terminal, tufted, aſcending, two or three inches long, doubly and very deeply pinnatifid, ſomewhat lyrate, ſlightly hairy; their ſegments linear-lanceolate, acute, entire. *Flowers* radical, at the baſe of each ſtem, quite ſeſſile, hemiſpherical, prickly all over with the innumerable prominent ſtyles, whoſe baſes are immerſed in a profuſion of ſoft whitiſh down, conſiſting of the hairs that crown each ſeed. The *ſeeds* are rounded at the ſummit, marked with two longitudinal acute ribs on their convex ſide, and with tranſverſe marginal furrows or plaits on the other, which laſt, in Juſſieu's figure, *e*, too much reſemble teeth, whereas the margin is nearly, if not quite, entire.

2. G. *naſturtiifolia*. Juſſ. ibid. t. 61. f. 2.—Leaves pinnatifid; ſegments elliptical. Flowers radical or axillary. Seed toothed at the top, corrugated on both ſides at the margin.—Gathered by Commerſon at Buenos Ayres. This has the habit of the laſt, except that, though a much ſmaller plant in every part, the *ſtems* are more elongated, and repeatedly forked. *Leaves* ſimply pinnatifid only, about an inch long, ſomewhat ſtalked, ſlightly hairy, obtuſe, their ſegments elliptical, pointed, entire, or rarely a little notched, ſo that their figure and ſize reſemble *Lepidium alpinum*, and ſome others of that family. *Flowers* numerous, ſcarcely bigger than a large pea, hemiſpherical, downy, ſolitary at the root and at each diviſion of the ſtem, encompaſſed by ſeveral ſpreading leaves. The *ſeeds* have on each ſide a longitudinal wedge-ſhaped depreſſion, encompaſſed with numerous, tranſverſe, marginal corrugations, and the top is notched or toothed, crowned with ſoft hairs ſurrounding the ſtyle.—Our learned and ingenious friend Mr. Correa (ſee CORRÆA) has led M. de Juſſieu into a miſtake as to *Hippia minuta*, Linn. Suppl. 389, which, having ſeen in the Linnæan herbarium here, he by memory conſidered as the ſame with this *Gymnoſtyles naſturtiifolia*. Their leaves indeed very much accord, but the *Hippia* has a longer and not dichotomous ſtem, with flowers not a fifth part ſo large, on ſtalks an inch long, and we believe the proper fructification of its genus, nor is there any of the preſumed errors in the Linnæan deſcription, the plant having the cloſeſt generic affinity to *H. frutescens*.

3. G. *pteroſperma*. Juſſ. ibid. t. 61. f. 3.—Leaves doubly pinnatifid. Flowers axillary. Seed with four dilated wings, ſlightly hairy, and two briſtles at the top.—Gathered by Commerſon with the laſt, from which it differs in its greater ſize, much longer and more branching, though ſtill always proſtrate, *ſtems*, and bipinnate *leaves*, which greatly reſemble thoſe of the firſt ſpecies, though rather narrower and more hairy. Their baſe or footſtalk is alſo more dilated and membranous. The *flowers* are quite ſeſſile, ſolitary, at the root and at each fork of the ſtem, not ſo villous, but very remarkable for their long prominent ſtyles, which are fringed at their baſe. The *ſeeds* too are very peculiar, being not crowned with long hairs, but with an awl-ſhaped briſtle on each ſide, like the ſtyle, though ſmooth, and parallel to it, except when they are occaſionally reflexed. The margin of the ſeed is dilated on each ſide into a larger and a ſmaller wing-like membranous expanſion, and the whole is ſlightly downy. S.

GYMNOTHORAX, in *Ichthyology*, a genus of the Apo-

dal order, eſtabliſhed by Bloch for the reception of thoſe ſpecies of the Linnæan and Gmelinian murænæ or eel family, which have no pectoral fin, and cannot therefore with propriety be referred to the ſame tribe as the eel, the conger, and others which have theſe fins.

The genus, according to Bloch, is diſtinguiſhed by being deſtitute of pectoral fins, to which material character it may be however added, that the body is anguilliform, viſcous, without ſcales, and variegated with very lively colours; the orifice of the ſpiracles or breathing organs ſtraight, inclining uſually to a ſomewhat oval form, and without either gill-cover or membrane; the mouth armed with ſtrong and ſharp teeth; noſtrils tubular; and the back and anal fin united with the tail. The ſpecies of this genus are not numerous.

Species.

Muræna. Brown, variegated with yellowiſh ſpots. Bloch. *Muræna Helena*, Linn.

This is the Roman eel, or muræna of the ancients, a fiſh of excellent flavour, and celebrated by their writers as one of the moſt luxurious articles of the table. The muræna is an inhabitant both of the freſh and ſalt waters, though, as Ariſtotle deſcribes, it lives principally in the ſea. Hirius was the firſt among the Roman epicures who conſtructed reſervoirs for the murænæ, but his example was ſoon followed, and became afterwards very general. In thoſe reſervoirs the murænæ were retained for amuſement or ſport, as well as uſe, and were, we are aſſured, rendered ſometimes ſo far docile, as to obey the ſignal of their maſter. The mention of theſe circumſtances naturally introduces to recollection, the well-known ſtory of Vedius Pollio, who, as Pliny relates, was in the habit of cauſing his offending ſlaves to be thrown into his reſervoirs of murænæ to be devoured; not, as that writer ſays, but there were wild beaſts enough on the land, but becauſe he took delight in ſeeing a man thus torn in pieces and eaten. This Vedius Pollio was one of the favourite followers of Auguſtus, notwithſtanding which, according to Seneca, the gratification of his cruel diſpoſition had nearly coſt him his life, upon its reaching the knowledge of that emperor: Auguſtus, it appears, one day honoured Vedius with his preſence at a ſplendid entertainment, when a ſlave happening to break a valuable cryſtal veſſel, the enraged maſter exclaimed, "away with him, caſt him to the murænæ!" And this ſavage order would, as uſual, have been executed, had not the poor youth thrown himſelf in a tranſport of deſpair at the feet of the emperor, and beſought that he might rather die by any death, than be the food of fiſhes. The emperor, aſtoniſhed at his requeſt, and being informed of this extraordinary mode of puniſhment, immediately directed all the cryſtal veſſels in the houſe to be broken before the face of Vedius, and his reſervoirs to be completely filled up, at the ſame time giving freedom to the ſlave, and only ſparing the life of the offender in conſideration of his former friendſhip.

The muræna inhabits many of the European and American ſeas, and abounds eſpecially on the coaſts of the ſouth of Europe. M. Cetti remarks that the muræna of Sardinia is covered with yellow ſpots. According to Cateſby there are two varieties in America, in one of which the ground colour is green, the other white, ſprinkled with black dots. In the drawings of Father Plumier, the prevailing colour is white, with yellow ſpots of large ſize, and the latter ſprinkled with ſmall black dots. It rarely exceeds the ſize of the common eel; the head ſmall, teeth large; and the bite dangerous; the uſual food polypes and fiſhes, and its appetite remarkably voracious.

Catenatus. Brown variegated, with white chain-ſhaped ſpots or bands. Bloch. *Muræna ſeu conger Braſilienſis*, Seba. *Gynothorax a bracelets*, Buff. *Marbled gymnothorax.*

About the ſize of a ſmall eel, the length being nearly twenty inches, and the thickneſs in proportion. The head is ſmall, as is likewiſe the opening of the mouth; the teeth ſmall, ſharp, and cloſe ſet; eyes ſmall and blue; ſnout furniſhed at the tip with two very ſmall ſetaceous beards; the breathing apertures very ſmall, and the lateral line ſcarcely perceptible. The ſpecies inhabits Surinam.

Reticularis. Whitiſh, banded with brown; ſides reticulated with brown; dorſal fin as long as the body. Bloch.

Reſembles the laſt in ſize; the head and mouth are ſmall; the eyes rather large, and ſituated near the upper lip; teeth diſtant and acute. A native of the Indian ſeas.

Afer. Fuſcous, marbled with white; gape wide. Bloch.

Bears a remote reſemblance to the Roman muræna. This ſpecies is found in the African ſeas, near the coaſts of Guinea. Iſert ſpeaks of it as a fiſh of good flavour and wholeſome, notwithſtanding which, the negroes will not eat its fleſh, conſidering the fiſh as a kind of marine ſerpent.

Zebra. Blackiſh brown, with tranſverſe linear white diſtant bands, meeting irregularly beneath. Shaw. *Serpens marina Surinamenſis fœmina murænis vulde affinis*, Seba.

Length two or three feet; the body ſerpent-form and without fins; head rather large and tumid; mouth and eyes ſmall; tentacula none. Native of the American ſeas.

Echidna. Head depreſſed; body varied with brown and black, and immediately behind the head very turgid. Ellis It.

Inhabits Palmerſton iſland; the length four or five feet; thickneſs ten or twelve inches. The general aſpect hideous, and much reſembling a ſerpent. The head ſmall; lips mucous; mouth horizontal, with two cirri near the noſtrils; eyes ſmall and vivacious; gape large; fleſh edible.

GYMNOTUS, a genus of the Apodal order, inſtituted by Linnæus, the character of which is thus deſcribed in the laſt edition of the "Syſtema Naturæ:" Head with lateral opercula; two tentacula on the upper lip; eyes covered with a common ſkin; gill-membrane with five rays; body compreſſed; beneath carinated by a fin. The eſſential character of the genus conſiſts, according to Bloch, in being deſtitute of a dorſal fin, and this opinion prevails with Lacépede and other continental authors, who only add that it wants the caudal as well as dorſal fin, and has the pectoral fin ſituated near the vent. In the adoption of this character, Lacépede was conſtrained to divide the Linnæan ſpecies of the Gymnotus tribe into two or more diſtinct genera, and this he has accordingly done, retaining to the firſt the term eſtabliſhed by Linnæus, and naming the two others he propoſes Apteronotus and Notopterus. The eſſential character of apteronotus is taken from the ſpecies albifrons, which differs from the reſt in having the tail furniſhed with a fin, and is the only ſpecies of its natural genus. Notopterus comprehends the two ſpecies notopterus and aſiaticus, both which, contrary to the Linnæan character of the Gymnotus, have a dorſal fin, beſides differing in ſome other material particulars. The ſpecies, excluſively of thoſe referred to the new genera laſt mentioned, amount to ſix in number.

Species.

* Gymnotus. *No Dorſal Fin.*

Electricus. Naked, blackiſh; tail obtuſe. Bloch, &c. *Gymnotus electricus*, Gronov. *Siddervis*, Act. Haarlem. *Gymnotus nigricans, cauda curta obtuſa*, Seba. *Electrical eel*, Hunter.

The length of this fiſh is from three to four or five feet; the head is ſhort and ſprinkled with perforated dots; the body blackiſh, with a number of ſmall annular bends or wrinkles; noſtrils two on each ſide, the firſt large, tubular, and elevated, the other ſmall, and not raiſed above the ſkin; the teeth ſmall; tongue broad, and with the palate warty.

The electric properties of this extraordinary creature have long rendered it an object of great curioſity among naturaliſts, the power it poſſeſſes in this reſpect ſurpaſſing even that of the torpedo. This animal was unknown to the philoſophers of Europe till about the year 1677, when an account of it was communicated to the French academy by M. Richer, one of the gentlemen deputed by the academy to conduct ſome mathematical obſervations in Cayenne, and in the rivers of which it appears to have been diſcovered for the firſt time by M. Richer. The ſciences not having at that period made any very conſiderable progreſs, the importance of this communication was not duly conſidered; nor indeed does it appear to have obtained that juſt ſhare of credit for veracity, to which it was unqueſtionably entitled, till nearly a century afterwards, when a full and general conviction of its accuracy was eſtabliſhed through the obſervations of Condamine, Ingram, and others. The experiments of Dr. Bancroft were not leſs ſatisfactory, as were alſo thoſe of Mr. Williamſon of Philadelphia, and Dr. Garden of Charlestown, in South Carolina.

From the obſervations of Condamine and others, engaged about the ſame time in a ſeries of experiments on the Galvanic properties of this fiſh, it is clearly demonſtrated, that the power of this animal conſiſts in a kind of genuine electricity, being equally capable of being conducted or intercepted by the ſame means as electricity. Thus, on touching the fiſh with the fingers, the ſame ſenſation is perceived as on touching a charged phial, being ſometimes felt as far as the elbows; and if touched by both hands, an electric ſhock is conveyed through the breaſt in the uſual manner.

Fermin, during his reſidence in Surinam, had frequent opportunities of examining this animal, and he has demonſtrated by experiment, that fourteen ſlaves, holding each other by the hands, received the ſhock at the ſame time, the firſt touching the fiſh with a ſtick, and the laſt dipping his hand into the water in which it was kept.

This electric faculty of the gymnotus is apparently deſigned by nature to aſſiſt in the ſupport of its exiſtence, the ſmaller fiſhes and other animals which happen to approach it being inſtantly ſtruck motionleſs, and, dropping to the bottom of the water, become an eaſy prey. The ſhock this fiſh is capable of exerting is ſo powerful as to deprive, almoſt entirely of ſenſe and motion, thoſe who are expoſed to its influence, and is therefore much dreaded by thoſe who bathe in the rivers it inhabits. Some writers affirm even, that the violence of the ſhock given by thoſe of a larger ſize is ſo great as to occaſion inſtant death.

The moſt copious general hiſtory of this ſingular creature that has appeared, is that addreſſed by Dr. Garden to the celebrated Mr. Ellis, the leading points of which it may be ſatisfactory to repeat. The largeſt of theſe fiſhes examined by Dr. Garden, was three feet eight inches in length, and the circumference about the thickeſt part from ten to fourteen inches. The head large, broad, and flat, ſmooth, and impreſſed here and there with holes, as if perforated with a blunt needle, eſpecially towards the ſides, where they are more regularly ranged in a line on each ſide. The roſtrum is obtuſe and rounded. The upper and lower jaws are of an equal length, and the gape large. The noſtrils are two on each ſide; the firſt large, tubular, and elevated above the ſurface; the others ſmall, level with the ſkin, and placed immediately behind the verge of the roſtrum, at the diſtance of an inch aſunder. The eyes are ſmall, flattiſh, and blueiſh, and placed about three quarters of an inch behind the noſtrils, towards the ſides of the head. The body is large, thick, and roundiſh for a conſiderable diſtance from the head, and then grows ſmaller, but at the ſame time deeper, or becomes of an acinaciform ſhape to the point of the tail, which is rather blunt. There are many light coloured ſpots on the back and ſides of the body, placed at conſiderable diſtances in regular lines, but more numerous and diſtinct towards the tail.

When this fiſh was ſwimming, it meaſured ſix inches in depth near the middle, from the upper part of the back to the lower edge of the fin, and the back at that part was not more than two inches broad. The whole body, from about four inches below the head, ſeems to be clearly diſtinguiſhed into four different longitudinal parts or diviſions. The upper part or back is roundiſh, of a dark colour, and ſeparated from the other parts on each ſide by the lateral lines; which, taking their riſe at the baſe of the head, juſt above the pectoral fins, run down the ſides, gradually converging, as the fiſh grows ſmaller, to the tail, and make ſo viſible a depreſſion or furrow in their courſe, as to diſtinguiſh this from the ſecond part or diviſion, which may be properly called the body, or at leaſt appears to be the ſtrong muſcular part of the fiſh. The ſecond diviſion is of a lighter and more clear blueiſh colour than the upper part, and ſeems to ſwell out ſomewhat on each ſide from the depreſſion of the lateral lines, but towards the lower or under part is again contracted into a kind of carina. This carina is very diſtinguiſhable from the other two diviſions by its thickneſs, its apparent laxneſs, and by the reticulated ſkin of a lighter colour, more inclining to grey. When the animal ſwims gently in pretty deep water, the rhomboidal reticulations of the ſkin of this carina are very diſcernible; but when the water is ſhallow, or the depth of the carina is contracted, theſe reticulations appear like many irregular longitudinal folds. The carina begins about ſix or ſeven inches below the baſe of the head, and, gradually widening or deepening, reaches down to the tail where thinneſt; this carina, where it firſt takes its riſe from the body of the fiſh, is about an inch or an inch and a half in thickneſs, and is gradually ſharpened to a thin edge where the fourth and laſt part is ſituated.

The ſituation of the vent in this fiſh is ſingular, being placed underneath, and about an inch more forward than the pectoral fins. Theſe pectoral fins, two in number, are placed, one on each ſide, juſt behind the head, and over the foramina ſpiratoria, which are ſmall and generally covered with a lax ſkin, ſituated in the axillæ of theſe fins. Theſe fins are ſmall for the ſize of the fiſh, being ſcarcely an inch in length, and of a very thin delicate conſiſtence, and orbicular ſhape. They ſeem to be uſeful in ſupporting and raiſing the head of the fiſh when he wants to breathe, which he does every four or five minutes, by raiſing his mouth out of the water. The body, or rather the rugæ of the ſkin of the body, is divided by a number of ſmall croſs bands or annulations, which reach acroſs down to the baſe of the carina on each ſide, but thoſe that croſs the back ſeem to terminate at the lateral lines, where new rings take their riſe, not exactly in the ſame line, and run down to the carina. This gives the fiſh ſomewhat of a worm-like appearance; and indeed it ſeems to have ſome of the properties of this tribe, for it has the power of lengthening or ſhortening its body, to a certain degree, for its own convenience or inclination. Dr. Garden obſerves that the ſpecimen which meaſured three feet eight inches, could ſhorten itſelf to three feet two inches, and that beſides this

power

power of extending or ſhortening its body, he could ſwim forwards or backwards with equal eaſe. When he ſwims forwards the undulations or wavy motions of the fin and carina begin from the upper part, and move downwards; but when he ſwims backwards, to the upper part of the body; and in either caſe he ſwims with equal ſwiftneſs. Every now and then the fiſh lays himſelf on one ſide, as it were to reſt himſelf, and then the four diviſions of the body before mentioned are very diſtinctly ſeen.

The power, ſays Dr. Garden, which it has of giving an electric ſhock to any perſon, or any number of perſons who join hands together, the extreme perſon on each ſide touching the fiſh, is its moſt ſingular and aſtoniſhing property. This writer ſpeaks of five which he examined at the ſame time; and theſe, he obſerves, poſſeſſed this power to a very great degree, and could communicate the ſhock to one perſon, or any number of perſons, either by the immediate touch of the fiſh with the hand, or by the intervention of any metalline rod. The keeper of theſe fiſhes told him, that when firſt caught, they could give a much ſtronger ſhock, by means of a metalline conductor, than afterwards. The perſon who is to receive the ſhock muſt take the fiſh in both hands, at ſome conſiderable diſtance aſunder, ſo as to form the communication, or he will not receive it; at leaſt, ſays Dr. Garden, I never ſaw any one ſhocked from taking hold of it with one hand only, though ſome have aſſured me that they were ſhocked by laying one hand upon it. I myſelf have taken hold of the largeſt with one hand often, without ever receiving a ſhock; but I never touched it with both hands, at a little diſtance aſunder, without feeling a ſmart ſhock. The ſhock which our Surinam fiſh gives ſeems wholly electrical; and all the phenomena or properties of it exactly reſemble thoſe of the electric aura of our atmoſphere, when collected, as far as they are diſcoverable, from the ſeveral trials made on this fiſh. The keeper of theſe fiſhes informed Dr. Garden that he caught them in Surinam river, a great way up, beyond where the ſalt water reaches, and that they are freſh-water fiſhes only. He ſays they are eaten, and, by ſome perſons, eſteemed a great delicacy. They live on fiſh, worms, or any animal food, if it is cut ſmall, ſo that they can ſwallow it. When ſmall live fiſh are thrown into the water, they firſt give them a ſhock, which ſo ſtupifies them, that they can ſwallow them eaſily, and without any trouble. If one of theſe ſmall fiſhes, after it is ſhocked, and, to all appearance dead, be taken out of the veſſel where the electric fiſh is, and put into freſh water, it will ſoon revive again. If a larger fiſh than they can ſwallow be thrown into the water, at a time when they are hungry, they give him ſome ſmart ſhocks, till he is apparently dead, and then endeavour to ſwallow or ſuck him in; but after ſeveral attempts, finding he is too large, they quit him. Upon the moſt careful inſpection of ſuch fiſh, this attentive obſerver could never ſee any mark of teeth, or the leaſt wound or ſcratch upon them. When the electric fiſh is hungry, it is pretty keen after food, but is ſoon ſatisfied, not being able to contain much at one time; and it further appears that a fiſh of this kind, three feet or upwards in length, cannot ſwallow a ſmall fiſh above three inches and a half long. They are ſometimes found in the river Surinam upwards of twenty feet in length; and the ſtroke or ſhock of one of theſe is ſaid to prove inſtant death to the perſon who receives it.

The very elaborate deſcription of the gymnotus, by the late Mr. Hunter, would ſeem to form an appropriate concluſion to the hiſtory of this intereſting animal, as it tends to explain, in a material degree, the nature and origin of the electric powers with which this fiſh is endowed, at the ſame time that they afford a more ample elucidation of its internal ſtructure in general, than has appeared from the pen of any other writer. The deſcription alluded to is inſerted in the Philoſophical Tranſactions, (vol. lxv.) and is accompanied by three plates of the muſcles and nerves. But having already given that deſcription under the article *Electric Organs of* Fish, it will be ſufficient to refer to that article.

Carapo. Naked, uniformly brown; lower jaw ſhorter; tail tapering to a point. *Gymnotus carapo*, Linn.

Length from one to two feet; the head of a compreſſed form; jaws with many ſharp teeth; eyes ſmall; front of the head marked, as in the former ſpecies, by a number of ſmall pores; body gradually tapering, and ending in a finleſs thread or filament. This fiſh is a native of the American ſeas, and is ſaid to be moſt frequent about the coaſts of Surinam. It is ſuppoſed to live chiefly on ſmall fiſhes, marine vermes, cruſtaceous animals, and inſects. Neither this, nor any other of the remaining ſpecies of gymnotus, ſeem to poſſeſs the ſame Galvanic properties as the firſt-mentioned kind.

Fasciatus. Naked, tranſverſely ſtriped; lower jaw longer; tail tapering to a point. Linn. *Banded gymnote.*

Differs chiefly from the former in the ſhortneſs of the tail, and inferior ſize of the body; and is conſidered by ſome as only a variety of that fiſh. It inhabits the ſame ſeas.

Albus. White, back convex; lower jaw longer; upper lip on each ſide with a ſmall lobe before the angle of the mouth. Pallas. *White gymnote.*

Size and general aſpect of the laſt; the colour white or whitiſh. The ſpecies inhabits Surinam.

Rostratus. Snout ſubulate; anal fin ſhorter than the tail. Seba, &c. *Snouted gymnote.*

Body ſpotted and ſomewhat acute. A native of Surinam.

Acus. Naked; no ventral fins; anal fin with ſixty rays, terminating before the tip of the tail. Brunnich. *Needle gymnote.*

Inhabits the Mediterranean; the general figure long, tapering, compreſſed, and ending in a point; the colour whitiſh with reddiſh and brown ſpots, and varied with a blueiſh tinge.

** Apteronotus. *Tail furniſhed with a Fin.*

Albifrons. Anterior part of the back ſnowy. *Gymnotus albifrons*, Pallas. *White-fronted apteronote.*

A native of Surinam, about a foot in length, ſharp, acute, and hoary, and the tail white covered with rounded ſcales. The head is very obtuſe, fleſhy, and ſprinkled with minute pores; mouth deep; upper lip very thick, and including the lower; pectoral fins black; anal beginning from the throat; tail compreſſed, flat, and oval; from the tip of the lower jaw to the middle of the back a ſnowy-white band.

*** Notopterus. *Back furniſhed with a Fin.*

Argenteus. Silvery with a gilt hue; fins pale aſh. *Gymnotus notopterus*, Linn. *Le notoptere kapirat*, Boſc. *Silvery notoptere.*

This ſpecies is about eight inches; the head ſhort and obtuſe; eyes large; upper jaw with few ſmall equal teeth at the edge; thoſe in the lower jaw larger and more diſtant; gill-cover ſcaly, with membranaceous edge; vent near the throat; anal fin more fleſhy, and narrower on the fore part. This fiſh inhabits Amboyna.

Asiaticus. Scaly; browniſh with deeper bands. *Gymnotus Aſiaticus*, Gmel.

A native

A native of Aſia, and in length not exceeding a ſpan. The head depreſſed, ſmoothiſh, with five hollow dots, and a ſmall hole in the front; before the noſtrils two truncated tentacula; tongue ſmooth; gill-covers at the ſides with a large gape; body ſomewhat cylindrical, and compreſſed behind; the dorſal fin beginning at the nape and reaching to the tail; lateral line elevated, ſtraight, deſcending before the anus.

GYNÆCEUM, among the *Ancients*, the apartment of the women; or a ſeparate place, in the inner part of the houſe, where the women keep themſelves retired, employed in their ſpinning, out of the ſight of the men.

The word is compounded of the Greek γυνη, *a woman*, and οικος, *a houſe*.

Under the Roman emperors there was a particular eſtabliſhment of gynæcea, being a kind of manufactories managed chiefly by women, for the making of clothes, furniture, &c. for the emperor's houſhold. Mention is made of theſe gynæcea, in the Theodoſian and Juſtinian code, and by divers other authors.

In imitation of theſe, divers of the modern manufactories, particularly thoſe of ſilk, where a number of women and maids are aſſociated and formed into a body, are called gynæcea.

GYNÆCIARIUS, a workman employed in the gynæceum. In the ancient gynæcea there were men to weave and ſhape; the reſt, as ſpinning, &c. being performed by women.

Criminals were ſometimes condemned to ſerve in the gynæcea, much as now in the gallies; frequently, alſo, this was a kind of ſervice which princes exacted of their ſubjects or vaſſals, both men and women, whom they made to work for them in their gynæcea.

GYNÆCOCOSMI, Γυναικοκοσμοι, in *Antiquity*, Athenian magiſtrates, whoſe buſineſs it was to regulate the women's apparel, according to the rules of modeſty and decency. See GYNÆCONOMUS.

GYNÆCOCRATUMENI, an ancient people of Sarmatia Europæa, inhabiting the eaſtern banks of the river Tanais, near its opening into the Palus Mæotis; thus called, as authors relate, becauſe they had no women among them; or, rather, becauſe they were under the dominion of women.

The word is formed of γυνη, *woman*, and κρατουμενος, *vanquiſhed*, of κρατεω, *I overcome*, q. d. overcome by women.

F. Hardouin, in his notes on Pliny, ſays, they were thus called, becauſe, after a battle which they loſt againſt the Amazons, on the banks of the Thermodoon, they were obliged to have a venereal commerce with them, in order to get them children: "Et quod victricibus obſequantur ad procurandum eis ſobolem."

Hardouin calls them the huſbands of the Amazons, *Amazonum connubia*; for, as the author obſerves, the word *unde* muſt be retrenched from Pliny, having been foiſted into the text by people who were not maſters of the author's meaning, *unde Amazonum connubia*.

They who take the Amazons for a fabulous people, will conclude the fame of the *Gynæcocratumenians*.

GYNÆCOCRACY, GYNÆCOCRATIA, a petticoat-government, or a ſtate where women have, or may have, the ſupreme command.

The word is formed of γυνη, γυναικος, *woman*, and κρατος, *authority, power, government*.

In this ſenſe, England and Spain are *gynæcocracies*: the French value themſelves, and think they are greatly happy, that their monarchy is not *gynæcocratic*.

GYNÆCOMASTOS, of γυνη, *woman*, and κομιζω, *I bear*; a term uſed by the ancients, to expreſs a man whoſe breaſts are large and turgid, like thoſe of women, and afford milk.

It was an obſervation among the ancients that ſuch men were naturally impotent. Paulus Ægineta obſerves, that the breaſts of men as well as women ſwell at the time of puberty, but that thoſe of women continue ſwelled, and thoſe of men ſubſide again, except in the caſe of the gynæcomaſtoi, where they remain turgid, and become in time more and more ſo, as the fat increaſes under them. As this ſwelling of the breaſts gave a ſuſpicion of impotency, thoſe who laboured under that deformity uſually had recourſe to a very painful operation in ſurgery to get rid of it. An inciſion was made in the form of a creſcent in the lower part of the breaſt, then the ſkin being drawn back, the fat was taken out, and the lips of the wound healed by means of a ſuture. When the breaſts were very large and hung down, they made two inciſions, one within the other, meeting at the extremities, and then ſeparating all the ſkin between them, they took out the fat: and finally, if the diſeaſe returned, or they had performed the operation imperfectly, leaving ſome behind, they repeated the whole a ſecond time.

GYNÆCON, in *Ancient Geography*, a ſea-port of Gedroſia. Ptol.

GYNÆCONOMUS, the name of a magiſtrate of Athens, who had the cenſure and inſpection of the women.

The word is compounded of the Greek γυνη, γυναικος, *woman*, and νομος, *law*.

There were ten gynæconomi; their buſineſs was to inform themſelves of the lives and manners of the ladies of that city, and to puniſh ſuch as miſbehaved themſelves, or tranſgreſſed the common bounds of modeſty and decency.

They had a liſt hanging out of the names of all thoſe whom they had cenſured, or condemned to any mulct, forfeiture, penance, or other penalty.

GYNÆCOPOLIS, in *Ancient Geography*, a town of Phœnicia. Steph. Byz.—Alſo, a town of Egypt. Strabo.

GYNÆSIA, a word uſed by the writers of medicine, ſometimes for the *menſtrua*, and ſometimes for the *lochia*.

GYNANDRIA, in *Botany*, from γυνη, *a woman*, and ανηρ, a *man*, alluding to the ſtamens being united with, or growing out of, the piſtil; the 20th claſs of the Linnæan artificial ſyſtem. Linnæus included in this claſs all plants of which the parts in queſtion were in any ſenſe united above the receptacle of the flower. Thus *Paſſiflora*, whoſe germen is elevated on a columnar baſis, and the ſtamens inſerted into the ſummit of the ſame part, juſt below it, was conſidered as Gynandrous. Such a principle is attended with great inconveniences, as in *Grewia*, ſome ſpecies of which have a conſiderable elevation of the germen, and others little or none. It is found therefore by far moſt convenient not to conſider ſuch inſertion or union at all, as the character of a claſs or order, unleſs it takes place upon or above the germen, or, in other words, unleſs the ſtamens grow out of the germen or ſtyle. Such is the caſe very decidedly in all the natural family of *Orchideæ*, as well as in *Forſtera* (ſee that article), and *Stylidium*. On theſe the claſs remains very firmly eſtabliſhed, and thus it conſiſts of three orders, diſtinguiſhed by the number of their ſtamens.

1. *Monandria*. Stamen one. This comprehends all the *Orchideæ*, except *Cypripedium*.

2. *Diandria*. Stamens two. Contains *Cypripedium* and *Forſtera*.

3. *Tetran-*

3. *Tetrandria.* Stamens four. Has only *Stilydium*, a curious New Holland genus, the *Ventenatia* of Sm. Exot. Bot. t. 66, 67. Its ſtyle is highly irritable, ſpringing over from one ſide of the flower to the other, on the ſlighteſt touch, by which its pollen is thrown with violence on the ſtigma.

The author of the preſent article has ſuggeſted, Introd. to Bot. 465, that this claſs might receive a reinforcement from the natural order of *Contortæ*, or *Aſclepiadeæ*; but he is happy to take this opportunity of retracting the hint. Whatever analogy there may be between ſome of that order, with reſpect to their anthers and pollen, and the Orchis tribe, and though they agree in their ſingular property of projecting the whole maſs of pollen, from each cell of an anther, entire on any extraneous body, they ſcarcely accord in any thing elſe. Mr. R. Brown has firſt underſtood this circumſtance in the *Aſclepiadeæ*, and has found that in them, as in the *Orchideæ*, the pollen is fully formed or ſecreted in the cells of the anthers, and, when ripe, is let go upon the glutinous points of the ſtigma deſtined to receive it, and on which it regularly ſticks in five double maſſes, looking exactly like anthers growing out of the ſtigma. But as the real ſtamens, which bear the ſecreting anthers, grow from the baſe of the flower as uſual, and not out of the germen, ſtyle, or ſtigma, in theſe *Aſclepiadeæ*, they muſt remain in *Pentandria*, whereas in the *Orchideæ* the anthers are really ſituated on the ſtyle, whoſe thick, columnar, oblique figure is altogether peculiar.

Vahl has referred the whole natural order of *Scitamineæ*, from *Monandria*, to which they truly and indiſputably belong, to *Gynandria*, merely becauſe he ſaw in one ſpecies of *Canna* a lateral cohefion between the flat ſtamen and ſtyle. But there is nothing of the ſort in genuine *Scitamineæ*, and it looks as if this ingenious author was rather led by a deſire to put off the evil day of arranging ſo difficult a tribe as long as he could, rather than by much knowledge of the ſubject. Since his death they have been clearly explained by Mr. Roſcoe, Tr. of Linn. Soc. v. 8. 330. t. 2, ſo that no further doubts remain, concerning either their claſſical or generic characters.

GYNANDRIA is alſo the name of an order of the claſſes *Monoecia* and *Dioecia* in Linnæus, founded on caſual abortion or imperfection of one or other of the organs of impregnation, and therefore untenable as well as paradoxical. S.

GYNDES, FORUM-EL-SALEH, in *Geography*, a river of Aſia, E. of the Tigris, into which it diſcharged itſelf a little to the N. of Apamea.

GYNOPLEURA, in *Botany*, ſo named by Cavanilles, from γυνη, *a woman*, and πλευρα, the *ſide*, on account of the inſertion of the ſtyles, or female organs, into the ſides of the germen, not into its top. Cavan. Ic. v. 4. 51.—Claſs and order, *Pentandria Trigynia*. Nat. Ord. *Salicariæ*, Juſſ.?

Gen. Ch. *Cal.* Perianth inferior, tubular, of one leaf, ſomewhat inflated, with five upright marginal ſegments, coloured, permanent. *Cor.* Petals five, equal, inſerted into the rim of the calyx, alternate with its teeth. Nectary? of ten blunt ſcales, ranged within the baſe of the petals, alternately broader with three, and narrower with two teeth. *Organs* of fructification elevated on a ſhort column. *Stam.* Filaments five, equal, longer than the calyx, thread-ſhaped, inſerted into the column a little below the germen; anthers incumbent, ſomewhat heart-ſhaped. *Piſt.* Germen ovate, ſlightly triangular; ſtyles three, inſerted a little below the top of the germen, into the middle of each of its valves, thread-ſhaped, the length of the filaments; ſtigmas capitate, peltate. *Peric.* Capſule ovate-oblong, of one cell, burſting at the top into three valves, united at their lower part. *Seeds* numerous, ſmall, ovate, inſerted alternately and uprightly into a linear receptacle along the centre of each valve.

Eſſ. Ch. Calyx tubular, five-toothed. Petals five, inſerted into its rim. Styles lateral. Capſule of one cell, and three valves. Seeds numerous, ranged along the middle of each valve.

Obſ. By Cavanilles' own account this appears to be the ſame genus, and the firſt the ſame ſpecies, with *Maleſherbiæ* of the *Flora Peruviana*, notwithſtanding the differences he mentions in the deſcription of the latter. We have not the work in queſtion to examine, and therefore retain his genus, the name of which is certainly the moſt eligible of the two, both for ſound and ſenſe.

1. G. *tubuloſa*. Cavan. Ic. t. 375.—Leaves lanceolate, unequally toothed. Calyx-teeth very ſhort. Petals acute.—Native of dry ſituations in the country at ſome diſtance from Lima. Whether the *ſtem* be herbaceous or ſhrubby we know not, but its branches are round, full of pith, downy, leafy. *Leaves* numerous, ſcattered, two inches long; lanceolate, plaited, acute, unequally toothed, very hairy on both ſides. *Flowers* in the upper part of the branch, numerous, from the boſoms of ſmaller leaves, which they rather exceed in length. *Calyx* an inch and a half long, tawny-yellow, membranous, ribbed, downy, ſlightly inflated, its teeth ſmall and rather unequal. *Petals* ſtill ſmaller, acute, fringed. *Germen* ſlender and nearly cylindrical. It flowers in July.

2. G. *linearifolia*. Cavan. Ic. t. 376.—Leaves linear, entire, fringed. Calyx-teeth as long as its tube. Petals obovate, obtuſe.—Native of the mountains of Chili, bearing flowers and ſeed in March and April. *Stem* three feet high, alternately branched, hairy. *Leaves* alternate, ſeſſile, linear, or ſomewhat lanceolate, obtuſe, entire, fringed, downy, auricled at the baſe: the lower ones longer and minutely ſerrated. *Flowers* axillary and terminal. *Calyx* funnel-ſhaped, ribbed, downy, its teeth bluntiſh and as long as the tube. *Petals* yellowiſh-white.

GYNOPOGON, from γυνη, a *woman*, and πωγων, a *beard*, becauſe of the ſuppoſed bearded ſtigma. Forſt. Nov. Gen. 18. t. 18. Mr. Brown, who found the deſcription of this genus very erroneous, and its name falſe, there being ſcarcely any ſpecies, out of eleven which he has examined, that has really a bearded ſtigma, adopted for it, from the manuſcripts of ſir Joſeph Banks and Dr. Solander, the name of *Alyxia*, alluding probably to ſome dull or gloomy aſpect in theſe ſhrubs, or to their being worn on mournful occaſions, from αλυξις, *anxiety*.—Brown Prod. 469.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ.

Eſſ. Ch. Corolla ſalver-ſhaped, naked at the mouth. Stamens included. Germens two, few-ſeeded. Styles imperfectly cohering. Stigma obtuſe. Drupas two, one of them occaſionally abortive, ſtalked, ſimple, ſingle-ſeeded, or elſe compound like a necklace, with an imperfectly two-celled coat. Seed half divided. Albumen eroded, horny. Embryo ſtraight.

The ſpecies are ſhrubby, ſmooth, milky. *Leaves* whorled or oppoſite, coriaceous, compact, evergreen. *Flowers* axillary or terminal, ſometimes ſpiked, among the ſmalleſt of their tribe, white, in many inſtances ſweet-ſcented. The eroded two-lobed albumen is conſidered by Mr. Brown as affording a very peculiar character.—Five ſpecies are de-

ſcribed

fined by this author as natives of the tropical part of New Holland. A. *ſpicata*, *tetragona*, *obtuſifolia*, *ruſcifolia*, and *buxifolia*.—Forſter mentions two; *ſtellata*, a native of Tonga Tabbu, which has ternate branches, and myrtle-like whorled leaves; and *ſcandens*, of Otaheité, whoſe leaves are larger and oppoſite.

GYPÆTI, in *Ornithology*, a diviſion of the genus *Falco*; which ſee.

GYPSARA, in *Geography*, a town of Mauritania Cæſarienſis; being a ſea-port between the great promontory and the town and colony of Siga: it was epiſcopal.

GYPSINE Stone, a name given by ſome writers to the *gypſum*, or foſſil ſubſtance, of which the powder called *plaſter of Paris* is made by calcination. There are in many parts of Arabia vaſt rocks of this ſtone: it reſembles alabaſter, but is ſofter, and of a more lax texture. It is found to be a very eaſy ſtone to form by tools, and therefore the Arabs build with it in ſome of the places in the neighbourhood of the quarries, but they are forced to make the walls very thick, as the ſtone is ſo ſoft and crumbly. The building called Arſoffa, or Arſoffa Emir, which ſeems the remains of a monaſtery, is built wholly of this ſtone; and when the ſun ſhines upon it, the walls give ſuch a luſtre, that they dazzle the eyes; but the ſoftneſs of the ſtone, and the redneſs of the mortar, have conſpired to make it a very ruinous pile at preſent, though of no great antiquity, the ſtones having ſplit and mouldered away in the walls, and the foundations failed in many places. Phil. Tranſ. N° 218, p. 150.

GYPSINUM Metallum, in the *Natural Hiſtory of the Ancients*, a name uſed for the common *lapis ſpecularis*, of which they often made windows as we do of glaſs. It was by ſome called *Cyprinum metallum*, becauſe frequently found in Cyprus.

GYPSOCHI, artiſts who work in plaſter. See Paradi-Gramatice.

GYPSOPHILA, in *Botany*, from γυψος, *lime*, or *plaſter*, and φιλεω, to *love*, becauſe the plants of this genus chiefly prefer a limeſtone or calcareous ſoil. Linn. Gen. 224. Schreb. 302. Willd. Sp. Pl. v. 2. 662. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 84. Sm. Prod. Fl. Græc. v. 1. 279. Juſſ. 301. Lamarck. Illuſtr. t. 375. (Saponaria; Gærtn. t. 130.) Claſs and order, *Decandria Digynia*. Nat. Ord. *Caryophylleï*, Linn. Juſſ.

Gen. Ch. *Cal.* Perianth inferior, ſimple, of one leaf, bell-ſhaped, angular, with five ovate ſegments, permanent. *Cor.* Petals five, obovate, obtuſe, ſcarcely ſpreading, nearly ſeſſile. *Stam.* Filaments ten, awl-ſhaped, ſlightly ſpreading; anthers roundiſh. *Piſt.* Germen nearly globoſe; ſtyles two, thread-ſhaped, ſeparate; ſtigmas ſimple. *Peric.* Capſule globoſe, of one-cell, with four or five valves united below. *Seeds* numerous, roundiſh.

Eſſ. Ch. Calyx of one leaf, bell-ſhaped, angular. Petals five, obovate, nearly entire. Capſule ſuperior, roundiſh, of one-cell.

Obſ. G. *paniculata* is dicœcious. This genus differs from *Dianthus* in having no ſcales at the baſe of the calyx, and from that of *Saponaria* in the angular form of the calyx, and ſhorter rounder ſeed-veſſel. By theſe marks, and by the moſt ſtriking agreement of habit, *Saponaria Vaccaria* of Linnæus is neceſſarily removed hither in Prod. Fl. Græc. nor is it eaſy to account for its having been placed any where elſe. *S. cretica* and *illyrica* are alſo *Gypſophilæ*. There being no where a complete and correct account of the whole, we ſhall attempt it here.

1. G. *Vaccaria*. Prod. Fl. Græc. n. 946. (Saponaria Vaccaria; Linn. Sp. Pl. 585. Vaccaria; Dod. Pempt. 104. Ger. em. 492.)—Leaves ovate, claſping the ſtem, very ſmooth. Petals emarginate, eroded.—Native of corn-fields in Germany, France, Switzerland, and the Levant, very common in Greece, and the iſlands of the Archipelago, flowering in June and July. *Root* annual, ſmall. Whole *herb* ſmooth, of a pale glaucous green. *Stem* one or two feet high, round, leafy, repeatedly forked above, corymboſe and many-flowered. *Leaves* oppoſite, claſping the ſtem, ovate, acute, entire, with a heart-ſhaped baſe, and one ſtrong rib with ſeveral ſmall ſhort lateral ones. *Flowers* about the ſize of a cowſlip, pink, with a very angular calyx tinged with brown or dull purple, inodorous. This is a hardy annual, of eaſy culture, ſowing itſelf ſpontaneouſly, and not unornamental.

2. G. *graminea*. Prod. Fl. Græc. n. 941.—Radical leaves linear, tufted. Stem panicled, nearly leafleſs. Petals emarginate. Calyx downy.—Suppoſed to have been gathered by Dr. Sibthorp on mountains in the Morea. This is a ſmaller plant than the preceding, with a perennial *root*, crowned with tufts of numerous, graſs-like, bright-green *leaves*, whoſe edges are rough with minute prickles. *Flowers* roſe-coloured, half the ſize of the firſt ſpecies.

3. G. *repens*. Linn. Sp. Pl. 581. Jacq. Auſtr. t. 407.—Leaves fleſhy, lanceolate. Petals emarginate, longer than the ſtamens.—Native of the Alps of Auſtria and Switzerland, and of the Pyrenean mountains. *Root* perennial, creeping, many-branched at the top. *Stems* numerous, a ſpan high, aſcending, nearly ſimple, forked above. *Leaves* elliptic-lanceolate, fleſhy, ſmooth-edged, about an inch long, often curved, ſcarcely glaucous. *Flowers* few, ſmaller than the laſt, whitiſh, with green ribs to the calyx. *Stamens* almoſt as long as the petals; *ſtyles* much ſhorter.

4. G. *proſtrata*. Linn. Sp. Pl. 581. (Alſine caryophylloides anguſtifolia multiflora glabra purpuraſcens; Pluk. Phyt. t. 75. f. 2.)—Leaves linear-lanceolate, ſmooth. Stems diffuſe, much branched, many-flowered. Styles prominent.—Preſumed to be a native of the European alps, but it is only known in gardens. The perennial *root* bears many diffuſe ſlender *ſtems*, a foot or two in length, very much branched and forked at their extremities. *Leaves* longer, ſharper, narrower, and leſs fleſhy, than the laſt. *Flowers* ſmaller, white, the ſtalks of thoſe that grow from the forks of the ſtem divaricated, or turned upwards. *Stamens* ſhorter than the corolla.

5. G. *paniculata*. Linn. Sp. Pl. 583. Jacq, Auſtr. append. t. 1.—Leaves lanceolate; the lower ones rough. Stems very much branched, divaricated, many-flowered. Styles prominent. Calyx rounded, obtuſe.—Native of dry ſandy ground in Siberia, and in Hungary about Buda. The *root* is thick and perennial. *Stems* diffuſe, more divaricated than in the preceding, repeatedly forked, and bearing innumerable minute white *flowers*, whoſe calyx has very round blunt ſegments, and whoſe *ſtamens* are ſhort and abortive in ſome flowers, while the piſtil is ſo in others, which according to Linnæus grow from a ſeparate root. The *leaves* are lanceolate, long-pointed, ſmooth, except the lower ones, which are more or leſs rough on both ſides

6. G. *viſcoſa*. Murray Comm. Gætting. for 1783. p. 9. t. 3. Ait. Hort. Kew. v. 2. 85.—"Leaves ovate-lanceolate, ſmooth, heart-ſhaped at the baſe and embracing the ſtem. Branches viſcid between their joints. Petals abrupt."—Native of the Levant, from whence its ſeeds were received by the late Mr. Forſyth. It is ſaid to be a hardy annual. This is the only ſpecies we have not examined.

7. G. *adſcendens*. Murray in Syſt. Veg. ed. 14. 415. Jacq. Hort. Vind. v. 2. t. 138.—Leaves linear, ſlightly lanceolate. Stems proſtrate. Panicles erect. Calyx acute.

Corolla, ſtamens, and ſtyles of equal length.—The native country of this is unknown. Jacquin received the ſeeds from profeſſor Spiellmann, and found the plant required a green-houſe in winter. The *root* is woody and perennial. *Stems* numerous, a foot long, proſtrate, red, leafy, aſcending only at the extremity, where they are forked and panicled. The *leaves* are ſmooth, near an inch long. *Flowers* white, the ſize of G. *repens*, with ſharp teeth and keels to the calyx. *Petals* emarginate.

8. G. *altiſſima*. Linn. Sp. Pl. 582. Prod. Fl. Græc. n. 942. (Lychnis caulibus dichotomis, corymbis faſtigiatis, foliis lanceolatis trinerviis; Gmel. Sib. v. 4. 143. t. 60.)—Leaves lanceolate, obſcurely three-ribbed. Stem erect. Calyx froſted.—Native of Siberia and Greece. *Root* perennial, tapering, long. *Stems* 18 to 24 inches high, erect, round, firm, leafy below, panicled and ſpreading above. *Leaves* from two to four inches long, and often half an inch broad, ſmooth, ſucculent; with three ribs, moſt viſible in a dry ſtate. *Flowers* corymboſe, crowded, ſmall, white, their calyx-ribs broad, obtuſe, green, froſted, the edges and interſtices broad and white. The *flower-ſtalks* are a little rough and clammy.

9. G. *arenaria*. Willd. Sp. Pl. n. 7.—Leaves linear, ſomewhat fleſhy, ſingle-ribbed, flat. Stem erect. Calyx ſmooth and naked.—Gathered in ſandy ground in Hungary by Meſſrs. Waldſtein and Kitaibel. As large as the laſt, and very like it in general appearance, but the *leaves* are ſmaller, and have no ſide-ribs. In our ſpecimen, ſent by the late Dr. H. A. Noehden from the Goettingen garden, they are all over minutely hairy, as is the panicle. The *flowers* are pale red, corymboſe. Their *calyx* ſmooth, ſcarcely at all downy or froſted, and its white edges far leſs conſpicuous than in G. *altiſſima*.

10. G. *Struthium*. Linn. Sp. Pl. 582. (Kali vermiculatum, albo globoſo flore; Barrel. Ic. t. 119.)—Leaves linear, fleſhy, ſemi-cylindrical; the axillary ones cluſtered.—Native of Spain. *Stem* erect, 12 or 18 inches high, woody below, leafy. *Leaves* crowded, an inch or more in length, linear, narrow, convex beneath, very ſucculent, glaucous, ſmooth, accompanied by ſhort, denſely-leafy, axillary branches. *Flowers* white, numerous, in denſe, rounded, panicled tufts. *Calyx* much as in G. *altiſſima*. *Petals* rounded, ſcarcely emarginate. This herb is ſaid to be uſed for ſcouring inſtead of ſoap, by the Spaniards at preſent, as it was by the ancients. It would be curious to enquire whether, like many ſucculent maritime plants, it contains foſſil alkali, and whether the reputed ſaponaceous quality of its near relative *Saponaria officinalis* be owing to the ſame cauſe, if indeed it really exiſts, which ſeems doubtful.

11. G. *faſtigiata*. Linn. Sp. Pl. 582. Ehrh. Phytoph. n. 85. (Lychnis, n. 41; Gmel. Sib. v. 4. 144 t. 61. Saponaria petalis ovatis, &c.; Rupp. Jen. ed. Hall. 117. t. 2.)—Leaves linear, obtuſe, ſmooth, ſucculent, obſcurely triangular, turned to one ſide. Flowers denſely corymboſe.—Native of rocks in Gothland, Germany, and Switzerland. *Root* woody, perennial. *Stems* a foot high, procumbent before flowering, which cauſes the *leaves* to turn upwards from the ground, and they, therefore, continue directed to one ſide. They are above an inch long, green, or purpliſh, narrow, fleſhy, and obtuſe. *Flowers* in denſe, corymboſe, forked tufts, with hairy *ſtalks*, membranous *bracteas*, a froſted bluntiſh *calyx*, and whitiſh rounded *petals*.

12. G. *perfoliata*. Linn. Sp. Pl. 583. (Spergula multiflora, foliis inferioribus ſaponariæ, ſuperioribus behen ſimillibus; Dill. Elth. v. 2. 368. t. 276.)—Leaves ovato-lanceolate; many-ribbed, half-claſping the ſtem. Flowers looſely panicled.—Native of Spain and the Levant. *Root* perennial. *Stems* two or three feet high, as thick as the little finger in their lower part, branched, leafy. *Leaves* two or three inches long, tapering, broad at the baſe, ſmooth or downy, the lower ones eſpecially many-ribbed, and moſt horizontal. *Flowers* the ſize of the laſt, pale red, copious, in looſe forked ſpreading panicles; their *calyx* ſmooth, but ſlightly membranous, or white at its edges. *Petals* entire.

A downy variety is the G. *tomentoſa*, Linn. Sp. Pl. 583, ſuppoſed to be what Barrelier figures, t. 1002, and alſo *Alſine altiſſima, folio plantaginis*; Buxb. Cent. 3. 32. t. 61. See Dill. Hort. Elth.

13. G. *muralis*. Linn. Sp. Pl. 583. Prod. Fl. Græc. n. 943. Ehrh. Herb. n. 154. (Betonicæ ſive Tunicæ minimæ ſimilis planta; Bauh. Hiſt. v. 3. 338. f. 1.)—Leaves linear, flat. Calyx without bracteas. Stem much branched throughout. Petals crenate.—On walls, rocks, and in ſtubble fields, in Sweden, Germany, Switzerland, and France. Dr. Sibthorp gathered it on the Bithynian Olympus.—A ſmall, biennial, upright, buſhy herb, with a ſlender, ſmooth, alternately branched, forked, panicled *ſtem*. *Leaves* oppoſite, very narrow, hardly an inch in length, ſometimes curved. *Flowers* copious, ſmall, pink, on ſlender ſpreading ſtalks an inch long, unaccompanied by any bracteas. *Calyx* very ſmooth, membranous betwixt the ribs. *Petals* ſlightly crenate, marked with fine reticulated veins.

14. G. *rigida*. Linn. Sp. Pl. 583. Prod. Fl. Græc. n. 944. (Tunica minima; Dalech. Hiſt. 1191. f. 2.)—Leaves linear, erect. Calyx accompanied by four equal ovate bracteas. Petals emarginate. Stems numerous, moderately branched.—Native of rocky dry places in the ſouth of Europe. Found on the Bithynian Olympus by Dr. Sibthorp. *Root* perennial, rather woody. *Stems* numerous, ſpreading, a ſpan long, leafy, ſimple below, a little branched alternately at the upper part, more or leſs downy. *Leaves* linear, or rather awl-ſhaped, erect, and nearly preſſed cloſe to the ſtem, ſhort, dilated, and membranous at their baſe; thoſe near the flowers ſhorter and more membranous. *Flowers* ſolitary, rarely in pairs, terminal. *Calyx* enveloped in four equal, ovate or obovate, membranous, rigid, pointed bracteas, rather ſhorter than itſelf. *Petals* pale purple, ſtreaked at the baſe of the border, emarginate at the point. *Stamens* unequal in length. *Styles* ſhort.

15. G. *ſaxifraga*. Linn. Sp. Pl. 584. Sm. Exot. Bot. v. 2. 61. t. 90. (Betonica coronaria, ſive Tunica minima; Bauh. Hiſt. v. 3. 337. f. 2.)—Leaves linear. Calyx accompanied by four unequal lanceolate bracteas. Petals emarginate. Stem very much branched.—Native of the ſouth of Europe, received by the late lady Amelia Hume from Spain. *Root* ſmall, fibrous, annual. *Stem* upright, ſlender, very much branched like that of G. *muralis*, with which this ſpecies agrees in habit, but is larger in every part, and eſſentially diſtinguiſhed by the four unequal lanceolate bracteas under the calyx, which have led ſome botaniſts, and even Linnæus originally, to make it a *Dianthus*. In this laſt reſpect it come ſo near the laſt, that few perſons know the one from the other, yet we believe the differences we have indicated are conſtant and ſufficient. The *petals* of G. *ſaxifraga* are emarginate, pale red, with three deeper ſtreaks. *Capſule* of four teeth or valves.

16. G. *dianthoides*. Prod. Fl. Græc. n. 945. (Lychnis orientalis, petalis albis, lineis cæruleis ſubtus variegatis; Tourn. Cor. 24.)—Leaves linear. Flowers capitate. Bracteas crowded, pointed, dilated, membranous. Petals obtuſe, entire. Gathered by Dr. Sibthorp on the Sphaciotic or White mountains of Crete. The *root* is woody and perennial. *Stems* many, a foot high, erect, moſtly ſimple, leafy, ſmooth. *Leaves* ſhort, linear, blunt, ſmooth, rather glaucous,

cous, moſt numerous on the lower part of each ſtem. *Flowers* two, three, four, or five together in terminal heads, in the manner of *Dianthus prolifer*, Engl. Bot. t. 956; with pale, ſcarioſe, lanceolate *bracteas* about them, nearly equal to the *calyx*, which is ſometimes downy. *Petals* entire, white above with three purple lines at the baſe of each, moſt beautifully reticulated underneath, near the margin with purple veins. *Capſule* cylindrical inclining to ovate, opening by four teeth or half-valves.

A figure of this, as well as of all the following, is deſtined to appear hereafter in the Flora Græca.

17. G. *cretica*. Prod. Fl. Græc. n. 946. (Saponaria cretica; Linn. Sp. Pl. 584.)—Leaves awl-ſhaped, three-ribbed. Stem partly forked. Border of each petal lanceolate, ſpotleſs. Root tufted.—Native of the rocks of Crete. *Root* woody, perennial. *Stems* numerous, erect, about a ſpan high, leafy, ſubdivided, forked, and ſomewhat panicled, ſlender. *Leaves* lanceolate, keeled, ſharp-pointed, three-ribbed in their lower part. *Flowers* ſolitary, terminal, very numerous, ſmall, their calyx and ſtalks downy, without bracteas. *Petals* narrow, entire, white above, purpliſh underneath. *Capſule* ovate, of four valves.

18. G. *ochroleuca*. Prod. Fl. Græc. n. 947.—Leaves awl-ſhaped; the lower ones linear and flaccid. Stem forked, divaricated. Border of each petal ſpatulate, ſpotted at the baſe.—Diſcovered by Dr. Sibthorp on the famous mount Hymettus, near Athens. The *root* ſeems annual. *Stems* numerous, of various heights, erect, branched, and forked almoſt from the bottom, at moſt a foot high. *Leaves* graſs-green, narrow, acute, ſingle-ribbed. *Flowers* like the laſt, except their petals being more ſpatulate, and pale ſtraw-coloured, elegantly dotted and ſtreaked with purple at the baſe.

19. G. *illyrica*. Prod. Fl. Græc. n. 948. (Saponaria illyrica; Linn. Mant. 70. Willd. Sp. Pl. v. 2. 669. Arduin. Specim. 2. 24. t. 9.)—Leaves awl-ſhaped. Stem forked, level-topped, downy and viſcid, as well as the calyx. Border of each petal obovate, dotted at the baſe.—Native of Dalmatia, and of the Archipelago. Dr. Sibthorp found it, flowering in Auguſt, on the hills of the iſland of Amorgos. *Root* biennial, according to Arduino, whoſe figure of this plant is in all its parts too large, though on the whole too dwarfiſh. We have compared his ſpecimens with thoſe of Sibthorp, a caution the more neceſſary, as this ſpecies is known to very few perſons. The *ſtems* are a ſpan high, leafy; ſimple below, each terminating in a denſe, forked, cloſe, level, downy and viſcid tuft, of ſmalliſh *flowers*, whoſe narrow, blunt, white *petals* have three purple dots at the baſe of their border. *Capſule* ovate, opening by four teeth. *Anthers* blue. The *leaves* are very finely toothed.

20. G. *ocellata*. Prod. Fl. Græc. n. 949. (Lychnis græca pumila umbellifera, polygoni folio, flore albo cum circulo atro-purpureo; Tourn. Cor. 14. Cucubalus polygonoides; Willd. Sp. Pl. v. 2. 690?)—Leaves ſpatulate, downy on both ſides. Stems diffuſe. Flowers capitate. Borders of the petals ovate, marked with a purple ring.—Native of mount Delphi in the iſland of Negropont, where Dr. Sibthorp gathered it. The *root* is long, thick, woody and tufted. Whole *herb* downy, light green. *Stems* numerous, diffuſe, three or four inches long, leafy, branched at the baſe only. *Leaves* rather above half an inch in length, ſpreading, ſpatulate, acute. *Flowers* about ſix or ſeven in each ſolitary terminal tuft, accompanied by a few ſhort leaves or bracteas. The broad white *petals* are beautifully marked with a common purple ring, as in *Dianthus deltoides*. We preſume there is no doubt of Tournefort's ſynonym, nor does Willdenow's deſcription differ very eſſentially from our plant, except that the petals are not emarginate, nor are the ſtyles three, as they ought to be in *Cucubalus*.

21. G. *thymifolia*. Prod. Fl. Græc. n. 950.—Leaves ſpatulate, downy on both ſides. Stems diffuſe, ſomewhat forked. Borders of the petals obovate, rounded, ſpotleſs.—Gathered by Dr. Sibthorp on mount Parnaſſus. This has the habit of the laſt, but the *ſtems* are rather longer, more diſpoſed to be branched or forked. *Leaves* ſhorter and rounder. *Flowers* two or three in each tuft, rarely axillary and ſolitary. *Calyx* hairy. Borders of the *petals* broad, rounded, white, entire, without any mark or ſpot. *Capſule* ovate, ſhort, four-toothed. The lower part of the plant is woody, and even ſhrubby.

GYPSUM, in *Agriculture*, a ſubſtance formed by the combination of the ſulphuric acid with calcareous earth; and which has been ſaid to have been found beneficial as a manure in different places, as in Germany, America, &c. but has not yet been tried with much ſucceſs in this country. See GYPSUM *infra*.

With reſpect to its uſe as a manure, it is aſſerted not to have been diſcovered until about the year 1768, at which period it was aſcertained to be beneficial in this intention by Mr. Mayer, a German clergyman.

It is ſuggeſted as probable, that it is the moſt advantageous on the drained clayey ſoils, being applied by ſpreading it out evenly, or ſowing it exactly over the ſurfaces of them in not too large a proportion about the month of February or the following one.

It ſeems probable alſo, that it is the moſt adapted to ſuch lands as are in the ſtate of ſward, though it may be employed on thoſe under tillage.

"In Maryland, in America, it is ſtated, in the ninth volume of the Agricultural Magazine, that comparative trials with this and other manures were made on rather a ſtony clay, mixed with a little loam, in order to aſcertain the beſt manure for wheat.

"A five-acre field (nearly a level ſurface) was divided into five equal parts, exactly an Engliſh acre each. They were equally well ploughed, and laid down in wheat, three Engliſh buſhels on each acre, after being manured as follows.

"On No. 1, was ſown ſix and a half buſhels of plaſter of Paris, or gypſum, pounded rather fine.

"On No. 2, was put a compoſt manure, which conſiſted of ſome lime. The bed of a freſh water river, common dung, &c.

"On No. 3, was cowpenned, as is uſual in America, by penning the cattle during night.

"On No. 4, was put ſtable-dung, only rather thin.

"On No. 5, lime was applied, in the uſual way, as in England and Ireland, with oyſter-ſhell lime.

"The produce of each acre was as follows:

"No. 1, produced full forty buſhels. N°. 2, thirty-ſix buſhels. No. 3, thirty-five buſhels. No. 4, thirty-three buſhels. And No. 5, thirty buſhels.

"It is obſerved that there was a want of rain in the ſpring, or they would have been greater. The ſeed-wheat was of the beſt Sicily grain, weighing 62lb. the Wincheſter buſhel, as imported into Virginia. The produce was a full round grain, weighing 63lb. the Wincheſter buſhel.

"The produce of No. 5, with the lime manure, was rather the fulleſt grain; and, as lime does not anſwer ſo well the firſt year, this acre will probably produce more hereafter.

"It appeared that dung, or organic matter, was the firſt

ſummer. The ſequel will prove, however, how much he was miſtaken; for, by referring to the ſubſequent ſtatement of the two perches, A, B, both gypſumed alike, and having an equal plant of clover, it appears that by ſuffering the wheat to ripen on B, there was a deficiency on the clover-ſeed amounting to 7*l.* per acre (a material object, had the three acres of loam been gypſumed), merely to gain two buſhels per acre of wheat, worth 15*s.* which he found the wheat product of the perch amounted to, proportioned to the acre. He has been induced to mention this circumſtance, not from its being in any wiſe the effect of gypſum, but to ſuggeſt what uſeful hints will frequently preſent themſelves in the progreſs of the moſt ſimple experiments, and ſometimes indeed of as much importance as the main object in view.

"Previous to a particular ſtatement of the experiments, it may be proper to obſerve, that the gypſum was ſown at the rate of ſix buſhels per acre, on the 22d of May; the clover at that time, particularly on the chalky ſoil, looked very pale, and wanted ſap; in a fortnight the gypſumed part might be diſtinguiſhed at a conſiderable diſtance; and though we had no rain, yet it ſoon formed ſo thick a mat, as effectually defended it from the ſcorching ſun, which nearly burnt up the reſt, as may be ſeen by the ſcanty products of the two contraſted perches A and B: as under is the ſtatement of the experiments alluded to."

Straw Product of Dutch-Clover.

	Per perch.	Per acre.	Net product.	Value at 1*s.* 6*d.* per cwt.
	lb. oz.	*cwt.* *qr.* *lb.*	*cwt.* *qr.* *lb.*	*L.* *s.* *d.*
A. Gypſumed	15 8	22 0 16	19 1 14	1 9 0¾
a. none	5 8	7 3 4	7 1 5	0 10 11
B. Gypſumed	15 0	21 1 20	19 3 18	1 9 10
b. none	9 0	12 13 12	12 1 8	0 18 6

Seed Product.

	Seed per perch.	Seed per acre.	Value at 12d. per lb.	Groſs amount.
	lb. oz.	*cwt.* *qr.* *lb.*	*L.* *s.* *d.*	*L.* *s.* *d.*
A. Gypſumed	1 15	2 3 3	15 10 0	16 19 0¾
a. none	0 5½	0 1 27	2 5 10	2 16 9
B. Gypſumed	1 1	1 2 2	8 10 0	9 19 10
b. none	0 6	0 2 4	2 10 0	3 8 6

It is ſuppoſed that "the reſults of the gypſum perches ſufficiently prove that it operates as forcibly on this plant as upon ſainfoin, with reſpect to groſs product; but the value of Dutch clover-ſeed being ſo ſuperior to that of ſainfoin, has occaſioned the money value of the ſeed product A. to exceed the higheſt ſainfoin-ſeed product No 2, as 3 to 1; and, upon deducting the groſs natural product *a* from the gypſum product A, it will appear that there is an abſolute gain of 14*l.* 2*s.* 3*d.* per acre, at the expence only of 16*s.* 6*d.* for ſix buſhels of gypſum.

"The invariable reſults of the ſeveral experiments, which are faithfully, and, he truſts, correctly ſtated, do, he thinks, incontеſtibly prove that there is a moſt powerful and ſubtile principle in this taſteleſs ſtone; but by what peculiar agency or combination it is capable of forcing vegetation in ſuch an inſtantaneous and aſtoniſhing manner, is a myſtery which time reſerves for others to unfold. But until this period arrive, the practical and moſt cautious farmer will, he hopes, run no great hazard in venturing ſome ſmall trials on the credit of the above matters of fact, which he has faithfully and truly ſtated." But the trials of ſir R. Sutton, as detailed in the Annals of Agriculture, are not, however, by any means ſo favourable. It is noted that in the courſe of the month of February he dreſſed, in his home farm, ſix acres of ground with pounded plaſter, ſix hundred weight to the acre; two of theſe acres were young red-clover, two white clover and graſs-ſeeds, and two natural meadow.—The ſoil where the red-clover was, a good hazel mould, with a ſtrong loam underneath; the others a ſtrong loam, more inclined to clay. At the ſame time he dreſſed eleven acres of young graſs-ſeeds on his foreſt farm, the ſoil ſand and gravel, and ten acres more of oats and barley, as ſoon as they came up; all at the ſame rate of ſix hundred weight per acre. He allowed double the quantity recommended by Mr. Schubart, on account of his plaſter running in a narrow vein, being ſeldom above an inch and a half thick, which was tranſparent and ſparkling; but could not be got without a good deal of a dead white ſtone, and ſometimes of a reddiſh ſtone clinging to it; the ſtrips were all choſe in the middle of fields, and accurately ſtaked out. Upon inſpection, at ſeveral different times during the growth of the crops, and at harveſt, no advantage could be perceived over the adjoining crops; his farmer, indeed, thought ſome had ſuffered by it; but in this he might be prejudiced. He calculated the expence of getting, carrying, grinding, and ſpreading the eight tons laid on twenty-ſeven acres, at 6*l.* 9*s.* By another trial, where it was laid on the proportion of 250 cwt. nearly on ſeven acres of his land, which is a ſtrong red loam, and thirteen acres of foreſt farm, ſand and gravel; it was laid on ſtrips amongſt the land, not dreſſed, and all on clover and graſs-ſeeds; and, upon inſpection, by ſeveral perſons, not the leaſt difference was perceived, either during any time of the growth, or at mowing; the plaſter was brought from Newark, of the beſt kind: he thinks he muſt infer from this, that the common plaſter is of a very different quality. The expence was as follows:

Statement.

On ſeven acres at Norwood.

	£.	*s.*	*d.*
One-third of the carriage - - -	0	4	0
One ditto of grinding - - -	0	16	8
Carrying out and ſowing - - -	0	5	0
One-third of 50 cwt. of plaſter - - -	0	4	2
	1	9	10

Or 4*s.* 3*d.* an acre, with a fraction: 5*s.* more ſhould be added for carriage, five and a half miles, and to the farm-field, or a little above, 4*d.* an acre.

In a further trial made with French gypſum, the reſult was nearly the ſame. On the 29th of April laſt, one buſhel was ſown upon a rood of land, meaſured and ſtaked out in the middle of a three-acred piece of red-clover, at his home farm, the ſoil a good loam; and the other, the ſame day, on the like quantity of land, likewiſe meaſured and ſtaked out in the middle of a piece of fifteen acres of white clover and graſs-ſeed, in his foreſt farm, the ſoil a poor ſand. During the whole day following, there fell a gentle ſoaking rain. However, being viewed at many different times during the growth, whilſt in ſwarth, and in after-graſs, there was not

not the leaſt perceivable advantage over the other lands, which had no dreſſing at all.

In Norfolk. according to the Survey of that diſtrict, lately publiſhed, "Mr. Allen tried this manure, very carefully, at Stanhow, on clean clover.

"March 31. No. 1 and 4. No manure; produce average of the two, 38lb. 6oz.

"2. Four quarts ſifted coal-aſhes kept dry, 50lb.

"3. Gypſum, one quart, 54½ lb.

"The aſhes, therefore, gave an increaſe of 11lb. 10oz. and the gypſum of 16lb. 2oz."

But more numerous and correct trials, made with greater attention to particular circumſtances, would ſeem to be neceſſary to aſcertain in what ſort and ſituation of land this ſubſtance may be employed with the moſt beneficial effects in producing crops.

In America, a late writer has found this ſubſtance to be only uſeful where the land was of the drier kind, and made rich by dung; and, not "to have been of any utility, except in clover." From the ſmallneſs of the quantity employed, he ſeems to think it improbable, that it contains any thing of the food of plants. He conſiders the principal uſe of it, to be that of attracting moiſture from the atmoſphere, and thereby hindering the heat of the ſun from affecting the ſoil to ſo great a depth, and the preventing of exhalation, as was evident from the darker appearance of the ground. It was in theſe ways, and that of defending the young plants from the ſcorching heat of the ſun, that it became ſo beneficial to turnips in his trials. "It covers the ſoil, and keeps the ground moiſt and cool all the ſummer." It is ſtated that it had a ſurpriſing effect on four rows of turnips in his firſt trial, which induced him to get a buſhel more, and ſow it upon another ſquare near a road, when, in twenty-four hours, he could diſcern the crop to be of a much deeper green; and, in forty-eight, ſo much ſo, as to have induced a belief of the ſoil being there of a ſuperior quality. He afterwards ſowed another buſhel of it on two rows, and miſſed two rows; the turnips grew to a much greater ſize where the gypſum was ſown, than in the reſt of the field, as in the proportion of about two to one in weight, where the two firſt buſhels were applied, and about three to two where the laſt buſhel was laid on; beſides being much more juicy and better in their kind. And, on the whole, he is not of opinion, that gypſum would anſwer ſo often, or ſo well, here as in America; but he doubts not of its being of great ſervice, and eſpecially on turnips in hot dry ſeaſons. This has, however, not yet been proved by actual trials made in this country.

It is ſuppoſed two buſhels will ſuffice for an acre in drills. French and Nova Scotia gypſum were uſed, being firſt ground fine. In this country, from ſix to eight buſhels have been employed per acre. The ſucceſs has, however, been very far from what might have been expected from the accounts that have at different times been publiſhed concerning it.

Gypsum, in *Mineralogy*, ſulphate of lime; *gyps* in German and in moſt other languages, from the Greek Γυψος. A combination of lime with ſulphuric acid.

This ſpecies may be divided into earthy, compact, ſtriated, foliated, and ſparry gypſum or ſelenite; the laſt of which is introduced by Werner as a *ſpecies*, while by other mineralogical writers it is conſidered as a ſub-ſpecies, or variety only. It matters little what appellations we give to ſuch ſub-diviſions: mineralogiſts will ever differ reſpecting the true principle of ſpecification; but fortunately the general arrangement of mineral ſubſtances is not materially influenced by this diſagreement. We ſhall conſider the above ſub-diviſions ſeparately.

1. *Earthy gypſum, gypſeous earth, mealy, farinaceous gypſum*, Engl. *Gyps-erde, gyps-mehl, gyps-guhr, Himmels-mehl*, &c. Germ. *Gyps-lera, Himmels-mjol*, Swed. *Gornaja gips*, or *gipſowaya muka*, Ruſſ.

Its *colour* is yelloviſh or greyiſh, and alſo reddiſh-white; the red and brown colour it ſometimes exhibits is moſtly owing to admixed iron-ochre.

It is compoſed of looſe, and ſlightly cohering duſt-like particles, and like chalk, rough and meagre to the touch. It is light.—Spec. grav.—

Among the *chemical characters* of the earthy gypſum, is its infuſibility, without addition, before the blow-pipe; it intumeſces only in a ſlight degree, and aſſumes a perfectly white colour; but with the addition of borax it melts with ebullition. When not perfectly ſaturated with ſulphuric acid, it effervеſces with nitric acid, and is diſſolved in it.

It *occurs* in Thuringia; in Saxony, in the circle of Neuſtadt, between Krölpa, Zella, Oepitz, and near Frankenhauſen; at Saltzburg, particularly at the Gypſberg, near Golling; in Bohemia, in Tranſylvania, in Norway. According to Brochant it has alſo been found at Mont-Martre, near Paris. This is, perhaps, the variety called by Haüy chaux ſulfatée *niviforme*: it is compoſed of cloſe grains of a white colour, with pearly luſtre, and occurs in maſſes appearing like ſnow-balls, and eaſily reducible into a ſoft powder; it is generally mixed with carbonate of lime. In Ruſſia it is found in the grottos of alabaſter on the banks of the Wolga, and the other rivers that unite with it.

Of its *geognoſtic ſituation* little is to be ſaid; it occurs as a rare mineral ſubſtance in the hollows of gypſeous mountains, where it is probably formed under ſimilar circumſtances as mountain-milk is in lime-ſtone rocks: it frequently originates by a ſolution of gypſum in water, whence, in the gypſum-countries, it is found more copiouſly in wet than in dry ſeaſons; and its occurring in the fiſſures of rocks of various nature likewiſe beſpeaks that origin.

At Frankenhauſen it has been ſeen by Mr. Freieſleben on the top of a gypſum-mountain, where it formed a ſuperficial ſtratum of about one foot and a half in thickneſs; it was not yet conſolidated, but was penetrated by a portion of water.

At Stemmitz, according to Shlotheim's obſervations, it occurs in earthy bituminous wood.

The *uſe* to which gypſum-earth is applied, in the Neuſtadt circle of Voigtland, is that of manuring and fertilizing barren land; as alſo that of white-waſhing walls. It is a melancholy circumſtance that dire neceſſity, together with the deſire of beguiling, if not the ſtomach at the leaſt the eye, ſhould have induced men to reſort to this moſt unpromiſing ſubſtance for nouriſhment. In Ruſſia it has been often employed as an admixture to flour in times of ſcarcity; a practice probably as deſtructive in its conſequences as famine itſelf!

2. *Compact Gypſum. Dichter gyps*, Germ. *Chaux ſulfatée compacte*, Haüy. *Geſſo compatto. alabaſtro*, Nap. *Calcareus gypſum denſum*, Wern. &c.—*Alabaſter, maſſive gypſum*, &c.

It is generally found of a yelloviſh and greyiſh-white, ſometimes nearly ſnow-white, leſs frequently of reddiſh-white colour; beſides which, we have the ſhades of green-iſh, blueiſh, honey-yellow, and browniſh-red. Several of theſe colours are ſometimes ſeen united as waved ſtripes, ſpots, veins, &c.

It occurs maſſive and diſſeminated.

Internally

Internally it is dull or faintly glimmering, and its fracture is even, partly splintery, sometimes passing into fine foliated and granular: fragments indeterminately angular, blunt edged, and more or less translucent, sometimes only on the edges.

It is very soft (scratched, like the following, by crystallized carbonate of lime); mild, easily frangible, meagre and cold to the feel. Sp. gravity 1.872—2.288, Kirw.—2.256, Gerh.—1.300, James.

The proportion of the *constituent parts* is stated by Mr. Gerhard to be the following,

Lime	36.00
Sulphuric acid	48.00
Water	16.00
	100.

It is found in England, in Derbyshire, &c.; in Lower Saxony, at Lüneburg, &c.; in Mansfeld; in Thuringia; in Poland, at Wielitzka, &c.; in Würtemberg, at Tübingen; in Suabia, at the abbey of St. Blasius; in Silesia, at Neuland, Freiburg, &c.; in Bavaria, at Hohenschwangen, in Tyrol; in Salzburg, on the Flachenberg, at Durenberg, &c.; in Austria, at Shottwein, Hallstadt, &c.; in Hungary, at Samberg, Herrengrund, &c.; in Transylvania, at Torda; in Switzerland; in France, Italy, Spain; in Russia, at Riga; in Siberia, at Catharineburg; in Persia, &c.

Compact gypsum *occurs* in considerable strata, generally in company with the other sub-species of gypsum, forming together particular fletz mountains. It is not unfrequently mixed with granular and foliated gypsum, into which it is sometimes seen to pass.

This sub-species is made *use* of in sculpture and architecture; it is (together with some modifications of foliated gypsum) the alabaster of modern mineralogists; the ancients applied the same term promiscuously to the gypsum, and to several of the coloured and pellucid varieties of stalactitical carbonate of lime. With regard to many of the productions of ancient art mentioned as being of alabaster, it is therefore impossible, from the mere imperfect descriptions we have of them, to determine to which of the two substances they should be referred. The white *Vasa unguentaria* of the ancients, to which also the name of alabastrites was given, were probably in part made of the white gypseous alabaster. The walls of the temple of *Fortuna Seia* were of a stone which we have reason to suppose was likewise compact gypsum; the interior of that edifice, though without windows, was rendered sufficiently light by the rays transmitted through its semi-pellucid walls. The Phengites of the ancients is supposed to be the same substance. At Florence the gypseous alabaster of Volterra is manufactured into vases, &c. that are remarkable for their translucidity; so that if a lamp be placed in them, a pleasing faint light is diffused over the room where they are kept.

The following varieties of gypseous alabaster are mentioned as susceptible of taking a good polish.

White gypseous alabaster of the Pyrenees: its colour is perfect snow white; fracture granular; the grain fine and close.

Milk-white alabaster of Boscadon, near Embrun, in the department of the High Alps. This, too, is of a fine close texture, and therefore susceptible of a good polish. The statues and basso-relievos of the superb mausoleum of the connétable de Lesdiguieres, in the cathedral of Gap, is constructed of it.

The alabaster of the river Niso, in Sicily, is of a light-grey colour, diversified with green and yellowish spots. Another good Sicilian gypseous alabaster is that found at Toarmina, in the Val Demona, on the sea-coast; it is marked with red and deep yellow waved streaks.

The whitish alabaster of Riquevire, in Alsace, is found in rounded masses mixed with other coloured varieties of compact gypsum, to which latter it is preferred, by the artists employed in working them.

The alabaster of the island of Goza, near Malta, is of a light yellow colour, with white waved streaks, and strongly translucid.

The alabaster of Lagny, near Paris, is of a yellowish-white colour, translucid, and of coarse granular fracture, which makes its fragments appear as if they were full of cracks; notwithstanding this, it is very firm and durable. It is also often traversed by blackish-grey veins. This alabaster, which takes a fine polish, is frequently employed at Paris for vases, slabs for tables, &c. There are some fine white varieties of white alabaster in Derbyshire, and other parts of England.

3. *Fibrous gypsum, Faseriger gyps, and calcareus gypsum fibrosum*, Wern. *Chaux sulfatée fibreuse*, Hauy. *Gesso fibroso*, Napion. *Stral-gyps*, Swed. *Feder-gyps, Federspath*, &c. Germ. *Striated or fibrous gypsum*, &c. Engl.

This sub-species presents a considerable suit of colours It occurs of snow-white and of greyish, yellowish, reddish, and greenish-white colour; besides which it has been observed ash-grey and light yellowish and greenish-grey, flesh, hyacinth, tile, and brownish-red; likewise honey and wax-yellow and oil-green. Several of these colours are often combined in spots, stripes, and veins in the same manner as in the compact gypsum.

It occurs massive, but generally only in thin layers: also dentiform, and in fancifully curled fibrous or plumose excrescences, sometimes resembling the head of a crosier, in Derbyshire and some other parts of England, in the Hartz, at Schemitz in Hungary, &c.

Its internal lustre varies from glistening to shining and splendent; it is often like the lustre of satin and mother-of-pearl.

Its fracture is mostly parallelly fibrous; fibres of various degrees of thickness, (from very delicate, bordering on compact, to coarse fibrous,) sometimes straight, at other times curved, seldom radiately diverging. There is a scarce variety, the longitudinal fracture of which is fibrous, while the transversal fracture is foliated.

Fragments indeterminately angular, mostly approaching to long-splintery; they are mostly semi-transparent.

It is very soft; and easily frangible. Specific gravity, according to Kirwan, 2.300.

The *localities* of fibrous gypsum are the same with those of the preceding sub-species, but it is less frequently met with. The variety mentioned above, as having a double fracture, is found at Wimmelburg, near Eisleben, in Saxony; the oil-green variety occurs at Nabra, in Thuringia. A fine satin gypsum is found on mount Salève, near Geneva.

This sub-species belongs for the greatest part to the newer formation of gypsum. Besides in thin layers, alternating with granular gypsum, it occurs also in the shape of small veins on strata of coal, &c.

It is sometimes *used* for ornamental purposes, and is manufactured into small boxes, &c. When cut *en cabochon*, and polished, it presents something like the locomotive sight of the cat's-eye, under which name such polished pieces are sometimes sold.

4. *Foliated gypsum, blättriger gyps, calcareus gypsum lamellosum*

ſum ſ. granulare, Wern. *Körniger gyps*, Karſt. *Granularly foliated gypſum*, Kirw. *Gypſe lamelleux*, Broch. *Geſſo lamellare*, Napion. *Fjällig gyps*, Swed.

The ſuit of colours of foliated gypſum is, upon the whole, the ſame as that of the preceding ſub-ſpecies; white, grey, yellow, and red being its principal colours: the grey preſents yellowiſh, blueiſh, and greeniſh tints; the yellow occurs as wine, honey, and wax-yellow, the red as fleſh, tile, and blood-red; of the darker colours we have olive-green, hair-brown, and greyiſh-black. All theſe colours occur ſometimes variouſly blended in the ſame fragment, in ſpots, veins, and ſtripes.

It is generally found maſſive and diſſeminated in blunt-edged, roundiſh, and kidney-ſhaped pieces; ſeldom in the ſhape of imperfect lenticular cryſtals, and ſimilar to one of the modifications of ſparry gypſum or ſelenite.

Internally its luſtre varies from ſhining to glimmering, and it is moſtly pearly.

Fracture foliated, generally rather curved, with ſingle cleavage; ſometimes the fracture appears ſtellularly diverging, with ſhort broad radii (ſtarry gypſum). Fragments indeterminately angular, rather blunt-edged.

It generally occurs in granular diſtinct concretions of various ſize, from coarſe to very fine granular: the ſmall and fine granular varieties have often ſo ſlight a coherence, that they can be eaſily reduced to ſand by the fingers, whence they have obtained the name of "Sandy Gypſum." The variety with radiated fracture often ſhows priſmatic diſtinct concretions.

It is more or leſs tranſlucent, ſeldom ſemi-tranſparent.

It is very ſoft, mild, eaſily frangible, and not particularly heavy. Specific gravity 2.274 to 2.310, Kirwan.

To the *localities* which the foliated gypſum has in common with the fibrous, the following may be added; Saxony, Freiberg; Luneburg; Thuringia, Dürrenberg, Nordhauſen, Weiſſenſee, Naumburg, &c.; Upper Bavaria, Oberau, Kolhel, &c.; Polonia, Krakau, &c.; France, Montmartre; England, Derbyſhire, Nottinghamſhire, &c.

The foliated or granular is the moſt common of the ſub-ſpecies of gypſum: it occurs in all the formations, but more particularly in the oldeſt. The primitive gypſum belongs partly to this, though it is alſo ſeen as compact gypſum: both theſe ſub-ſpecies often occur together. It is not ſeldom porphyritically mixed with compact gypſum and ſelenite, with compact and granular lime-ſtone, quartz, arragonite, boracite; and is alſo, particularly in the newer formations, accompanied by clay, native ſulphur, and celeſtine. It alſo occurs with fetid carbonate of lime or ſtinkſtone, ſometimes in alternating layers, forming parallel ſtripes; ſuch as at Bottendorf in Saxony, and below the ſtink-ſtone at Frankenhauſen, and between Roſsleben and Wendelſtein in Thuringia. It is now and then ſo intimately mixed with ſtink-ſtone, that, on ſcratching a fragment, it emits the well known urinous or hepatic odour, whence in Gallicia it is termed Leber-ſtein or Leber-ſpath; names which are alſo given to foliated gypſum or ſelenite impregnated with aſphaltum, and to ſome other mineral ſubſtances.

The above-mentioned ſtellated variety is found in ſeveral parts of Germany; alſo at Durham, &c.

5. *Sparry gypſum* or *ſelenite*. *Spathiger gyps*, Karſten. *Broad-foliated* or *ſpecular gypſum*, Kirw. *Fraueneis* and *calcareus ſelenites*, Werner. *Gypſe ſpathique ſelenite*, Broch. *Chaux ſulfatée criſtalliſée*, Haüy. (Vulg. *marienglas*, Germ.; *Talc, pierre ſpeculaire, miroir d'Ane*, Fr. &c.)

The colour of ſparry gypſum is principally white, *viz.* ſnow, greyiſh and yellowiſh-white, alſo ſmoke and aſh-grey, and yellowiſh-grey paſſing into wax and honey-yellow, and this into yellowiſh and clove-brown. It occurs alſo, though rarely, of blood and of fleſh-red, and of a browniſh-black colour: the red colour is generally produced by iron ochre.

It is found maſſive and diſſeminated, ſeldom as coating, betroidal or ſmall reniform: moſt frequently it occurs cryſtallized.

All the *cryſtals* of this ſubſtance we are acquainted with may be conſidered as derived from a low priſm, having for its baſe a rhomb, whoſe angles are about 127 and 53°. The following are the principal modifications.

1. The moſt common and ſimple is that which appears as a tabular ſolid, the broad planes of which are rhombs bevilled on the four edges by trapezoidal planes, two oppoſite pairs of which meet under an angle of 144°, the two others under that of 111°. This is the *Chaux ſulfatée trapèzienne* of Haüy. (Pl. 33. fig. 96.) By Werner it is conſidered as a ſix-ſided priſm, having two oppoſite planes larger and four oppoſite ſmaller, and bevilled on both extremities, the bevilling planes ſet obliquely but parallel to each other on the broader lateral planes. This ten-ſided rhombic cryſtal is ſometimes enlarged parallelly to the planes that meet under an angle of 144°, ſometimes to thoſe that meet under an angle of 111°, by which the cryſtal is either widened or elongated. Sometimes, too, the planes that meet under an angle of 144° are exactly of the ſame width as the two rhombic planes, when the tabular is loſt in the columnar form.

This modification occurs alſo as twin cryſtals or macle, (Chaux ſulfatée trapézienne hémitrope,) in which at one end a re-entering angle of 106 5′ 36″ is formed, and one of the ſame value, but which projects its point outward, on the other end. Tranſparent cryſtals thus macled, when held between the eye and the light, generally exhibit the plane of the junction as a delicate ſtraight line.

2. The preceding modification, in which the acute ſolid angle formed at each end of the cryſtal by the meeting of four of the trapezoidal planes, is replaced by two equally trapezoidal planes, which meet under an angle of about 139°. This is the Chaux ſulf. *équivalente* of Haüy. (Pl. 33. fig. 98.) In the Wernerian manner of conſidering this modification, it is the ſame flat ſix-ſided priſm as the preceding, but acuminated on both ends by four planes ſet on the lateral edges that bound the two larger planes.

3. Another, but rare modification, is that called by Haüy Chaux ſulfatée *prominule*. It is a kind of macle, exhibiting the form of an eight-ſided priſm, very flatly acuminated by four planes. (See Haüy ii. p. 272. Pl. 34. fig. 99.) Sometimes in the cryſtal, No. 1, thoſe trapezoidal planes that meet under an angle of 144°, and the acute ſolid angle at each extremity of the cryſtal, are rounded off, while the other trapezoidal planes, meeting under an angle of 111°, remain perfect: this forms the paſſage into the

5. Lenticular cryſtals. Theſe are either ſolitary or columnarly aggregated, and confuſedly grouped together with the ſharp edges uppermoſt, (coxcomb ſelenite, gypſe en erête de coq,) or circularly arranged like the petals of a flower (gyſpe en roſe); or two and two are united near part of the edges, ſo that they form, on one ſide, a re-entering angle, and a prominent one on the other: if two lenticular cryſtals thus connate are broken in the direction of the large planes of the laminæ, and at the ſame time in ſuch a manner that the fragments remain cohering, theſe latter often exhibit ſomething like the form of the head of an arrow, and have been erroneouſly conſidered as a diſtinct variety, under the name of *gypſe en fer de lance*, or *gypſe cuneiforme*. Laſtly, the lenticular cryſtals are ſometimes diſpoſed in pairs, elevated one above the other, in ſuch a manner that each pair

 inſinuates

insinuates itself, by its prominent angle, into the re-entering angle of the one immediately under it. Many of these lenticular combinations are found in great variety at Montmartre.

All the crystals of this substance have a remarkable tendency to altering their figure by exfoliation. Some will split into diverging laminæ to a certain extent only: they are compared to, and also go by the name of, Lions' paws, in some parts of England. For the theory of the various alterations which these crystals undergo, by their tendency to assume a rounded form, see Haüy's Traité, vol. ii. p. 274. seq.

The rhomboidal, columnar, and acicular crystals are frequently seen grouped together in various manners, sometimes crossing each other in all directions, also in fascicular and stellular aggregations, and in druses. Sometimes small crystals are inserted in, and traverse larger crystals.

With regard to their size, the crystals vary from exceeding large (not only lenticular, but also perfect crystals have been found of above a foot in length, but they are scarce,) to very small.

The trapezoidal planes of the crystals are generally longitudinally striated, owing to the direction of the laminæ, the the two others perfectly smooth: they are generally more or less splendent.

Internally the sparry gypsum is specular-splendent. Its fracture is generally straight, sometimes curved foliated; this is the perfect cleavage, which is easily obtained: but there are two others less perfect ones, which, with the former, produce the rhombic solids already mentioned as representing the primitive form.

When massive it generally presents itself in large, and coarse grained, and sometimes in imperfectly thick cuneiform and columnar distinct concretions.

It is generally completely transparent, very soft and mild, flexible in a low degree, when divided into thin plates, rather tenacious, the laminæ preserving the curvature given them by means of an imperfect rupture of their parts; it is not particularly heavy, its specific gravity being stated as 2.311 by Kirwan, as 2.322 by Muschenbroeck, but only as 1.761 (that found at Naumburg) by Gellert.

The component parts of sparry gypsum, according to Bergmann, are

Lime - - -	32.00
Sulphuric acid -	46.00
Water - -	22.00
	100

Bergm. Opusc. vol. i. p. 135.

Its *localities* are in general those of the other sub-species of gypsum; the following deserve particular mention: France, particularly in the neighbourhood of Paris; England, Oxfordshire, Isle of Sheppey, &c.; Thuringia; in the fletz mountains at Frankenberg, Bottendorf, Wendelstein, Nebra, Weissenfels, Naumburg, &c., Saxony; in Upper Lusatia, at Muskau, and Wehrau; Bohemia; particularly in the Leutmeritz and Saatz circles; Upper Austria, Ischel, Hallstadt; Hungary, Herrengrund at Neusohl, Schemnitz, &c.; Transylvania, Felsobanya, Vizakna, &c.; Saltzburg; in the Durenberg; Tyrol, Hall, &c.

Sparry gypsum, or selenite, is chiefly met with in the oldest gypsum formation; partly in more or less considerable masses, partly in stratification; as likewise in detached crystals in beds of clay; also with calamine, and in beds of bituminous wood, and alum earth. It is sometimes found, mostly as the newest fossil, in veins, for instance, of copper and lead: at Herrengrund, near Neusohl, it occurs in veins of copper pyrites, and grey copper ore, and near Tetschen, in Bohemia, in veins of galena. It has also been found with native gold, and, by Patrin, in the Smenovsky silver mines in the Altaic mountains, where it occurs in schistus. Nor is it unfrequently seen in the form of beautiful acicular crystals, in old neglected mines, on old hillocks of pits, &c., as a substance of very recent formation. In volcanic countries it occurs in acicular crystals, on native sulphur, and is generally met with in abundance near depositions of rock-salt, such as in those of Saltzburg and Upper Austria.

When mixed with clay it sometimes exhibits the lustre called *chatoyant;* to this variety the name of Schiller-gyps has been given by miners in Germany. When intimately mixed with flink-stone it has a smoke-grey colour, and on being rubbed emits the peculiar odour of that substance.

Geognostic Relation of Gypsum in general.—Werner distinguishes three distinct formations of gypsum.

1. The *oldest gypsum* —It occurs in primitive mountains, and is therefore called primitive gypsum. It has been observed at Belinzona or Belentz, as also at Airolo in the Levantine or Livener valley, on the southern part of mount Gothard, in a micaceous schistus, by Freiesleben, and others; and at Cogne in the High Alps (*Grandi Alpi* of the Italians,) by Daubuisson, whose account of it we subjoin the more readily, as the period of the formation of the first mentioned gypsum has been doubted by some geologists. The southern part of the Alps, from Mont Blanc to Mont Rose, belongs almost exclusively to the formation of micaceous shistus. Here this primitive rock frequently includes strata of primitive lime-stone, serpentine, chlorite, magnetic iron, &c.: sometimes it passes into argillaceous shistus, but oftener into gneiss and granite. About 15,000 metres southward from the town Aoste, and eastward from Cogne, a mountain is seen, which constitutes part of the chain that separates the valley of Cogne from that part of Fenes; this mountain is terminated by a sharp edge, elevated more than 2100 feet above the level of the valley, and consists of micaceous shistus in nearly horizontal strata: in its upper part this rock is mixed with lime-stone in gradual proportions till, in some parts, it exhibits itself as a white granular lime-stone only, containing here and there some particles of mica. It is nearly 62 feet below the most elevated part of the summit of this mountain, that the *primitive gypsum* is seen. There it is visible only for the length of about twenty-three feet, its thickness being rather more than three feet: all the rest of its extent is hidden by a great quantity of boulders and masses of rock, that, being rolled from the summit, have covered the sides of the mountain, so that nothing positive can be said respecting its extent in length and thickness, nor respecting the circumstances of its super-position; Daubuisson has, however, seen traces of it at more than 150 feet distance from the place where it is laid open for the purpose of working quarries. Its thickness cannot be considerable, for at the place of the quarries, the rock in which it occurs (which is a deep grey micaceous and calcareous shistus, traversed by veins of calcareous spar and quartz,) makes its re-appearance at the depth of some yards. These quarries the workmen have advanced about seven feet under the shistus, so that this work now forms a kind of roof, beneath which the work is carried on. In this place it clearly appears, that the shistus is resting on the gypsum: they both appear in perfectly parallel strata; those of the gypsum are not many inches in thickness, and are often separated from each other by a greenish talcose coating.

This primitive gypsum is of a beautiful white colour, sometimes with a slight tint of rose-red; its grain is crystalline,

fine, very fine, and similar to that of Carrara marble; it is very transluciid and mild. If it could be obtained in sufficiently large pieces without fissures, it might pass for a fine alabaster; but at present it is employed only for masonry, and it yields a good cement.

It includes much talc in detached pieces, generally of a lenticular form and of various sizes, from very small to the size of a hazel-nut: these are almost always disposed with their flat sides downwards, and parallelly with the stratification; their colour is a very fine green. Sometimes the laminæ of the talc are in so close contact among each other, that a compact mass, like that of steatite, is produced; at other times their laminæ are very narrow and resemble fibres; and such fibres are now and then seen disseminated through the gypsum in small groups, which being of a fine light green colour, might easily be mistaken for amianth.

What has been said respecting the parallelism of the stratification of the gypsum and micaceous shistus, as well as respecting the presence of the talcose or steatitic substance in those two rocks, places their synchronism beyond a doubt; both the nearly horizontal position of the strata from the foot to the summit of the mountain, and the identity of the rock which forms the roof and the sides of the stratum of gypsum, do not leave room for the idea, that, by the effects of a revolution, a portion of secondary gypsum, deposited on the mountain posterior to its formation, might have been covered by a mass of shistus. In this case the gypsum is actually a component part of the mountain, and, indeed, one of anterior origin to several other primitive rocks placed above it.

2. *Transition gypsum*, described by Mr. Von Buch, who observed it at Leogang, in Salzburg, in greywacke slate. It is of a close texture, and has a fine crystalline grain. Its strata are inconsiderable, bent in various directions, and mixed with coloured clay. It affects several colours. M. Brongniart refers to this formation the gypsum which he has observed between Bayonne and St. Jean-de-Luz, at the foot of the Pyrenees; that of Vizille, near Grenoble; that of Dessises, in the department of the Cote-d'Or; that of the Salines of Bex, in Switzerland, &c.

3. *Fletz-gypsum.*—Werner adopts two distinct formations of fletz-gypsum; the *first*, resting on the first fletz-limestone, and covered by the variegated sandstone, runs through great part of Germany. It first appears in Holstein, forms a gypseous tract at Luneburg (where it contains boracite crystals), in Thuringia (where it includes quartz crystals), in Anspach, Bavaria, Silesia; also in Switzerland (where sulphur, both massive and crystallized, is often found in it), in the south of France, at Arragon in Spain (where arragonite occurs in it). The great deposition of gypsum on the banks of the Wolga also belong to this formation. On the relationship in which the rock-salt and salt-springs stand to fletz-gypsum, see ROCK-SALT.

The *second* fletz-gypsum is super-imposed on the variegated sandstone, and is covered by the second limestone. It is not known to occur porphyritic by means of imbedded crystals of boracite, arragonite, quartz, &c. like the first formation, nor is it equally abundant. It forms, however, considerable strata in Saxony, Silesia, Bavaria, in France, near Toulon, at Aix, and also occurs in Cumberland and Cheshire: as to the gypsum of Derbyshire, we have it observed by Mr. Jameson, that the formation to which it belongs is unknown, "as no well educated geognost has ever communicated any observations regarding it." This second formation appears to contain fossil remains. The occurrence of fibrous gypsum is particularly characteristic of it.

Besides these two principal and well-determined formations of fletz-gypsum, there are two others whose nature is not satisfactorily ascertained, *viz.* the gypsum of Sparenberg, in the Mark Brandenburg, and that of Neuland, near Löwenberg, in Silesia. To these may be added the gypsum of the neighbourhood of Paris; but not as a dubious one, for the observations lately made upon it by Cuvier and Brongniart, with an account of which we shall conclude this part of the present article, have proved it to belong to a formation very distinct from, and of more recent date than, those already mentioned.

The gypseous formation of Paris is not composed of gypsum alone, but strata of it alternate with argillaceous and calcareous marle: they follow the same order of superposition in the whole gypseous tract, from Meaux to Triel and Grisy, and though in a few districts some strata are wanting, yet those that remain constantly affect the same relative position. The gypsum is placed immediately above the limestone. The gypseous hillocks and elevations have a particular appearance by which they may be distinguished at a distance, being always placed on the limestone; they form, as it were, another set of elongated or conical, but always distinct hills, resting on the calcareous eminences.

Montmartre, as well as those hillocks that appear to be a prolongation of it, exhibit three distinct masses of gypsum; the lowermost is composed of alternate and not very thick strata of gypsum (frequently passing into sparry gypsum), of solid calcareous and of very foliated argillaceous marles. It is in the former of these in particular that the large yellow lenticular crystals of sparry gypsum are found: the foliated argillaceous marle (or adhesive slate), contains the variety of silex called menilite. No fossil substances have as yet been found in the third gypseous mass.—The second, or intermediate mass, differs from the preceding only in this, that the beds of gypsum are thicker, and that the strata of marle are less numerous. It is chiefly in this mass that fossil fishes have been discovered; also celestine (sulphate of strontian), has lately been found in it in kidneys towards the base of a stratum of a compact grey marbled variety of marle belonging to this second mass.—The superficial mass of gypsum, which the workmen call the first, is, in every respect, the most remarkable, and the most important. It is, besides, much thicker than the rest, having in some parts no less than about 82 feet in thickness; it is interrupted only by a small number of marley strata, and, in some places, as at Dammartin and Montmorency, it is situated almost immediately under the vegetable mould.—The lowermost beds of this first mass contain flints that appear to pass over into, and to be penetrated by, the gypseous matter. The intermediate beds have a tendency to separate into large prisms with several planes that are well described and figured by M. Desmarest. Lastly, the uppermost beds of this first mass are penetrated by marle; they have but little thickness, and alternate with strata of marle.

More particularly interesting are the observations that have been made by the same ingenious naturalists on the secondary fossils contained both in this mass and in the marle that covers it. It is in this first gypseous mass that are found skeletons of unknown birds and quadrupeds. To the northward of Paris they occur in the gypseous mass itself; here they have preserved their solidity, and are only coated by a very thin layer of calcareous marle; while in the quarries to the southward they are often found imbedded in the marle that separates the strata of gypsum; they have there a high degree of friability. Also bones of tortoises, and skeletons of fishes, have been found in this mass.—On the circumstances under which these remains of birds, &c. are

found in this mafs of gypfum, the determination of the fpecies to which they belong, &c. very intereſting memoirs have been given by Cuvier, in the Annales du Muſeum d'Hiſtoire Naturelle.

But a circumſtance on which great ſtreſs is laid by Meſſrs. Cuvier and Brongniart, is, that in the gypſeous bed in queſtion freſh-water ſhells have been diſcovered. Theſe ſhells are, indeed, of rare occurrence; but a ſolitary one would, in the opinion of the above-mentioned naturaliſts, ſuffice to demonſtrate the truth of what has been aſſerted by Lamanon and others, namely, that the gypſum of Montmartre, and of other hillocks of the baſin of Paris, have originated by cryſtallization in freſh-water lakes. Another eſſential character of this uppermoſt maſs of gypſum, is the preſence of ſkeletons of mammiferous animals, no traces of which have been diſcovered in the lower maſſes.

On this uppermoſt maſs of gypſum reſt ſtrong ſtrata, both of calcareous and argillaceous marle. It is in the lowermoſt of theſe beds, in a white, friable, calcareous marle, that petrified trunks of palm-trees have been found: they were all of a conſiderable ſize, and appeared in a horizontal poſition. In the ſame ſeries of ſtrata (but only at Romainville) have been found ſhells belonging to the genera of lymnæa and planorbis, and theſe appear not to differ in any reſpect from the ſpecies ſtill exiſting in the marſhes of France. This appears to prove that theſe marles, as well as the gypſum on which they reſt, are the productions of freſh water. Above theſe white marles are ſeen a great number of other ſtrata of argillaceous and calcareous marle, in which, however, no foſſils have as yet been diſcovered. The next is a ſmall ſtratum, about four and twenty inches thick, of a yellowiſh foliated marle, which, towards its lower ſurface, contains nodules of earthy ſulphate of ſtrontian, and, a little above, a thin layer, or ſmall lengthened tellinæ, lying flat, and preſſed cloſely againſt each other. This ſtratum is remarkable on account of its conſiderable extent, combined with extraordinary thinneſs; and alſo becauſe it ſerves as a limit to the freſh-water formation, and indicates the ſudden commencement of a new marine formation. Indeed, all the ſhells found beneath this bed of tellinæ are alſo marine. This is immediately and regularly ſucceeded by a ſtratum of a greeniſh clayey marle, which may be recognized at a great diſtance by its thickneſs, colour, and continuity. It ſerves as a guide to arrive at the tellinæ; for it is beneath it that theſe ſhells are found. No foſſils are diſcovered in it but argilo-calcareous geodes and nodules of ſulphate of ſtrontian. The four or five beds of marle that ſucceed the green clays are not thick, nor do they appear to contain any foſſils; but theſe beds are immediately covered by a ſtratum of a yellow clayey marle, mixed with fragmentary remains of ſhells, the prototypes of which belonged to the genera cerites, trochus, mactra, venus, cardium, &c. Alſo fragments of the palate of a ray analogous to the ſea-eagle are found here. Almoſt all the beds of marle that ſucceed the latter exhibit foſſil ſea-ſhells, but they are bivalves only; and the laſt ſtrata, namely, thoſe that are immediately below the clayey ſand, contain two pretty diſtinct oyſter beds: the firſt and lowermoſt of them is compoſed of large very thick oyſter-ſhells. This is ſucceeded by a ſtratum of a whitiſh marle without ſhells, after which comes a ſecond very thick oyſter-bed, but ſubdivided into ſeveral diſtinct beds. Theſe oyſters are brown, much ſmaller, and of a thinner texture than the preceding ones. The formation of gypſum is often terminated by a maſs, more or leſs thick, of clayey ſand, which is without ſhells.

Such are the ſtrata that generally compoſe the formation of gypſum in the neighbourhood of Paris. The authors of the memoir, of which the above is extracted, were inclined to divide them into two, and to ſeparate the hiſtory of the marine marles of the top from thoſe of the freſh-water marles and gypſum at the bottom; but the ſtrata are ſo ſimilar to each other, and accompany each other ſo conſtantly, that they preferred merely to point out this diviſion, without really making it. The principal differences preſented by the hillocks that belong to the gypſum formation of Paris, according to the ſame authors, are the following: The gypſeous hillocks form a kind of long and broad zone, directed from the ſouth-weſt to north-eaſt, over a breadth of about ſix leagues. It appears, that in this zone it is only the eminences of the centre which exhibit diſtinctly the three maſſes of gypſum; thoſe of the edges, ſuch as the plaſter-quarries at Clamart, Bagneaux, Antoni, Mont-Valerian, Griſy, &c. and thoſe of the extremities, ſuch as the plaſter-quarries of Chelles and Triel, ſhew a ſingle maſs only. This maſs ſeems to be analogous to that which the workmen call the firſt, (namely, the moſt ſuperficial,) becauſe the characteriſtic foſſil-remains of mammiferæ are found in it; and becauſe its marles are without thoſe large and numerous lenticular cryſtals of gypſum which are obſerved in the marles of the ſecond and of the third maſs. Sometimes the marles above are almoſt entirely wanting; ſometimes the gypſum itſelf is totally wanting, or reduced to a thin bed. In the former caſe, the formation is repreſented by the green marles, accompanied with celeſtine; the gypſeous formations of the park of Verſailles, near St. Cyr; thoſe of Viroflay are in the former predicament; thoſe of Meudon, of Ville d'Avray, are in the latter. From all that has been ſaid, it appears, that the formation of gypſum, of the environs of Paris, is a depoſition diſtinct from the two formations of fletz gypſum deſcribed by Werner. It approaches neareſt to the ſecond fletz gypſum of this naturaliſt, but differs principally by its reſting on the ſecond lime-ſtone, inſtead of being covered by it, and its not being placed on, or alternating with, the variegated ſand-ſtone. M. Brongniart is inclined to refer alſo the gypſum of Aix to the Paris gypſum-formation; though, as he obſerves, the foſſil fiſhes of the quarries of Aix are found in bituminous marle, and not in the gypſum. M. Gillet Laumont thinks that of Aigue-perce, in the department of Puy-de-Dôme, likewiſe comparable to the gypſum formation of Montmartre.

The *chemical character* of gypſum is, generally ſpeaking, the ſame in all the ſub-ſpecies. When expoſed to heat, it loſes its water of cryſtallization, becomes opaque, and falls into a white powder (termed plaſter), which abſorbs water rapidly, and ſoon becomes hard. It is almoſt infuſible without addition, but the ſparry gypſum or ſelenite appears to undergo partial vitrification, when expoſed to the intenſe heat of the blow-pipe. We are told by Macquer, that to effect this purpoſe, it is neceſſary to apply the point of the flame in the direction of the laminæ, inſtead of cauſing it to act perpendicularly on their ſurface. Haüy accounts for this circumſtance by obſerving that the integrant molecules, being priſms whoſe length exceeds the dimenſions of the baſe, adhere ſtronger by their lateral planes than by their baſes; and hence their ſeparation, both by mechanical means and the action of caloric, will be more difficult in the direction of their lateral planes than in that of their baſes.

In a ſtill more intenſe heat, (ſuch as that produced by a ſtream of oxygen-gas, and in the ſtrongeſt concentrated ſolar light) it appears to loſe great part of its ſulphuric acid, the ſeparation of which from the lime is manifeſted by a penetrating ſmell. Under theſe circumſtances, it fuſes into

into a white glaſs, which, however, is ſaid ſoon to fall into a white powder.

In the charcoal crucible, according to Klaproth's experiments, the ſparry gypſum had turned white and very friable, with the loſs of 60 *per cent.* of its weight; but in the clay crucible it had melted into a clove-brown glaſs, with large ſpherical veſicles.

Sulphate of lime is ſoluble in water; but it requires not leſs than five hundred times its weight of water, and a mean temperature. It does not effervesce with acids, nor is it decompoſed by any of them; it may be diſſolved by the ſulphuric acid, but the ſolution is decompoſed by water. Its decompoſition may, however, be effected by barytes and the fixed alkalis, when boiled with them in water: it is decompoſed, alſo, by a double affinity, when boiled in a ſolution of the alkaline carbonates.

The *uſe* made of the ſeveral ſub-ſpecies of gypſum for economical purpoſes is of conſiderable importance. They poſſeſs the quality of improving, by a chemical combination not perfectly underſtood, the quality of the ſoil, eſpecially when too ſtiff and clammy, and are, therefore, frequently employed for the manuring of land, both in Europe and America.

Gypſum, when deprived of its water of cryſtallization by heat, is called plaſter. Of this the coarſer ſorts are employed, with the admixture of common lime-ſtone, for cements. The gypſum, which naturally contains carbonate of lime, makes very good cement; but that which has an admixture of clay and ſand, affords a cement of an inferior quality.

The kilns in which the plaſter-ſtones are burnt are generally of a very ſimple conſtruction; often they are built of gypſum itſelf. The fragments to be calcined are looſely put together, in ſuch a manner as to form a parallelopipedic heap, below which are vaulted pipes or flues, for the application of a moderate heat. The calcination muſt not be carried to exceſs, ſince in this caſe the plaſter will be deprived of its quality of forming a ſolid maſs when mixed with a certain portion of water. During the proceſs of calcination, the water of cryſtallization riſes as a white vapour, which, if the atmoſphere be dry, is quickly diſſolved in air.

On the river Wolga, in Ruſſia, the burning of gypſum conſtitutes one of the chief occupations of the peaſantry. They calcine all kinds of gypſum promiſcuouſly, on grates made of wood, they then reduce the plaſter to powder, paſs it through a ſieve, and form it into ſmall round cakes, which they ſell at from 1 to $1\frac{1}{2}$ ruble per thouſand.

In order to make uſe of the plaſter, water is added to the powder, which is produced by pounding the calcined fragments; an operation performed either in mills conſtructed for the purpoſe, or by the hands of men, whoſe health is much impaired by the pernicious effects which the duſt of this ſubſtance has upon the lungs.

The leſs the gypſum intended for plaſter is mixed with other ſubſtances, the better it is qualified for the purpoſe of making caſts, ſtucco, &c.; the ſparry gypſum or ſelenite, which of courſe is the pureſt of all, is employed for taking impreſſions from coins and medals (ſee IMPRESSIONS); and for thoſe beautiful imitations of marble, granite, and porphyry that are known by the name of *Scagliola*, derived from the Italian word *ſcagli*, or laminæ of ſelenite, which latter is vuglarly called talc in Italy and France, and alſo in England.

GYPSUM *Anhydrous*. See MURIACITE.

Gypſum is often found in very regular ſtrata, between, or accompanied by, red, blue, or grey marle, and by ſtrata of rock ſalt, and ſalt ſprings. In other ſituations the ſtrata of gypſum are feather-edged, or forming large, irregular, and very flat nodules in the marle, and even amorphous maſſes or irregular lumps of great thickneſs and extent. Theſe appearances ſeem to ariſe from the gypſum not forming regular or continuous ſtrata in the marle, which is its matrix, but accidental beds, or nodules, of all ſizes and ſhapes, as is obſerved of the argillaceous iron-ſtone nodules in their uſual matrixes of ſhale, bind, or clay (except that theſe laſt are never very large), and of other nodular imbedded ſubſtances.

The nodular maſſes, or accidental beds, of the vaſt ſtrata of red marle which occur in England beneath the lias ſtrata, and above the yellow or magneſian limeſtone ſtrata, are, as Mr. Farey has obſerved (Phil. Mag. vol. xxxi. p. 40.), among their moſt curious and important phenomena. The vaſt concretions, nodules, or confuſedly cryſtallized maſſes of gypſum, limeſtone, rock-ſalt, ſienite, ſlat, baſalt, ſand, micaceous fine grit-ſtone, very coarſe grit or pudding-ſtone, brick-clay, &c. and perhaps local fields of argillaceous and carboniferous ſtrata or coal-meaſures, which are found alternating with, or ſurrounded by red marle (containing often light blue ſtreaks or patches), cover the greater part of the ſurface of England and Wales, north and weſt of the regular baſſet or edge of the lias clay and limeſtones; and it ſeems probable that it has been owing to the local ſtripping off or denudations of this red marle, that nearly all of the important ſtrata containing coal and argillaceous iron-ſtone have been laid bare or expoſed, for the uſe of man in theſe iſlands.

It ſeems probable that there are ſeveral other ſtrata of gypſeous marle, beſides the Britiſh above-mentioned, in different parts of the world. Thoſe of the environs of Paris are certainly upper ſtrata to the chalk of the ſouth-eaſt of England (ſee Phil. Mag. vol. xxxv. p. 131.), and greatly above the Engliſh red marle ſtrata. It ſeems, however, that gypſum, and ſalt rocks and ſprings, are common in all ſuch diſtricts; and the other anomalous maſſes mentioned above have been noticed by authors in many of them. Gypſum has been mentioned as the produce of the following kingdoms, ſtates, &c. *viz.* Algiers, the Archipelago N. Aſtrachan, Auſtria (Upper), Bavaria, Calabria, England, France, Hartz, Hungary, Italy, Minorca iſle, Parmia, Poland, Pruſſia, Savoy, Saxony, Siberia, Spain, Swiſſerland, Tranſilvania, Tunis, Weſtphalia, &c.

The following liſt of places where gypſum is dug in England, France, &c. may prove intereſting to many of our readers, *viz.*

Aix, near Avignon, in France.
Ambaſton (Ballington Hill) S.E. of Derby.
Antoni, 11 miles W. of Paris, in France.
Aſton, three miles S. of Derby.
Bagneaux, $4\frac{1}{2}$ miles S. of Paris, in France.
Chellaſton, three miles S. of Derby.
Chelles, near Paris, in France.
Ciamart, $5\frac{1}{2}$ miles S.W. of Paris, in France.
Clifton, S.W. of Nottingham.
Cold Aſton, Glouceſterſhire.
Crowle, near Thorne (York), in Lincolnſhire.
Dammartin, 14 miles N.E. of Paris, in France.
Fairburn, near Pontefract, Yorkſhire.
Frankenberg, in Saxony.
Gotham, S.W. of Nottingham.
Griſſy, near Paris, in France.
Hanbury, N.E. (Fauld Hill), N. (Coton and Rowbank), Staffordſhire.
Hanbury (Auſt-paſſage), Glouceſterſhire.
Horninglow, N. of Burton, Staffordſhire.

Marchington (Hound Hill), Staffordſhire.
Meaux, ſix miles S.W. of Paris, in France.
Meandon, near do.
Mingranilla, in Valentia, in Spain.
Mobberley, in Cheſhire.
Monte-martre, 2½ miles N. of Paris, in France.
Montmorency, 10 miles N.E. of do.
Mont Valerian, near Paris, do.
Newark, E. in Nottinghamſhire.
Ratcliff (Red Hill) S.W. of Nottingham.
Stinchcombe, E. of Berkley, Glouceſterſhire.
Syſton, N. of Leiceſter.
Thorne, in Yorkſhire.
Triel, near Paris, in France.
Tutbury, S. (Caſtle Hay) Staffordſhire.
Tuxford (Markham-Moor) Nottinghamſhire.
Ville-d'Avray, eight miles W. of Paris, in France.
Whitehaven, E. Cumberland.
Witton, near Northwich, Cheſhire.

The marly tracts, where gypſum and rock-ſalt are found, ſeem ſubject to circular depreſſions, or FUNNEL-*ſhaped* hollows (ſee that article), which are noticed by Mr. Jameſon, "Geognoſy," p. 34 and 172.

GYPSUM is uſed in the Canaries by way of remedy for their wine; and about Malaga a large quantity is turned up with the juice of their grapes.

GYPSUM *Tymphaicum* is a name given by the ancients to the white chalk, which was eſteemed by them for the cleanſing of clothes, and which makes an excellent plaiſter or cement without previous burning. See CALX *nativa*.

GYPSY, a name given to a ſet of vagrants. See EGYPTIANS and GIPSIES.

GYRATION, *Centre of*, in *Mechanics*. When any ſyſtem of bodies, as A,B,C, (*Plate* IX. *Analyſis, fig.* 1.) is cauſed to revolve round a centre S by the action of a force applied at a given diſtance, which remains unchanged, there will exiſt ſome point R in which, if all the matter A + B + C be collected, the ſame force applied at the ſame diſtance will generate the ſame angular velocity in the ſame time as if the bodies were diſpoſed at their reſpective diſtances S A, S B, S C: this point is called the *centre of gyration*.

N.B. The moving force is here meant to act in the direction of the plane wherein the ſyſtem revolves, and at right angles to a line drawn from the point at which it is applied perpendicular to the axis.

Before we can demonſtrate the method of finding the centre of gyration, it is neceſſary to premiſe a few elementary principles in the doctrine of rotatory motion.

1. If a body be collected into a point B (*fig.* 2.) and revolve round an axis of motion paſſing through S, by the action of a force P applied at the diſtance S D from the axis; it is required to aſſign what quantity of matter muſt be collected in the point D, ſo that D may be accelerated in the ſame manner as when B revolved at the diſtance S B, and conſequently that the angular velocity of B and D round S may be the ſame in both caſes.

When any two bodies are put in motion by two conſtant forces acting for the ſame time, the quantities of matter moved are in a direct ratio of the moving forces, and an inverſe ratio of the velocities generated; that is, if $\frac{M}{m}$ expreſſes the ratio of the moving forces, $\frac{Q}{q}$ that of the quantities of matter, and $\frac{V}{v}$ that of the velocities generated, the relation of theſe quantities is defined by the equation $\frac{Q}{q} = \frac{M}{m} \times \frac{v}{V}$.

To apply this, it muſt be obſerved, that although the abſolute force of the weight P acting upon the point D, remains conſtantly the ſame, yet its effects upon bodies placed at different diſtances from the axis of motion are in the inverſe proportion of thoſe diſtances; therefore the moving forces exerted by P on the points B and D will be in the proportion of S D to S B: alſo, by the problem the angular motions of B and D are equal, and conſequently the velocity of B is to the velocity of D, as S B : S D; and ſince the quantities of matter in B and D are in the direct proportion of the moving forces, or of S D : S B, and an inverſe proportion of the velocities generated, or of S B : S D, we ſhall have the quantity of matter in B to that contained in D, as $S D^2 : S B^2$, and conſequently the weight ſought $= B \times \frac{S B^2}{S D^2}$.

Or thus, let x = the quantity of matter required to be collected in D, M the moving force which acts on B, m that which acts on D, V the velocity of B, v that of D; then will $\frac{B}{x} = \frac{M}{m} \times \frac{v}{V}$, but $\frac{M}{m} = \frac{S D}{S B}$ by the property of the lever: moreover $\frac{v}{V} = \frac{S D}{S B}$ by the nature of angular motion, wherefore $\frac{B}{x} = \frac{S D^2}{S B^2}$, and $x = B \times \frac{S B^2}{S D^2}$.

Cor. 1.—Whenever a body B revolves round an axis, by the action of a conſtant force P, applied at a given diſtance, S D, from the axis; in order to find the force which accelerates D, the maſs B may be ſuppoſed to be removed, and inſtead of it an equivalent weight $B \times \frac{S B^2}{S D^2}$ collected in the point D to which the force is applied.

Cor. 2.—Since the moving force is P, and the maſs moved $\frac{B \times S B^2}{S D^2}$, (the inertia of P not being conſidered,) the force which accelerates D will be that part of the acceleration of gravity which is expreſſed by the fraction $\frac{P}{B \times \frac{S B^2}{S D^2}} = \frac{P \times S D^2}{B \times S B^2}$.

Cor. 3.—Let any number of bodies A, B, C, (*fig.* 3.) be put in motion round a fixed axis paſſing through S, by a conſtant force P applied at D, the point D will be accelerated in the ſame manner, and conſequently the whole ſyſtem will have the ſame angular velocity: if inſtead of A, B, C, &c. placed at the diſtances S A, S B, S C, we ſubſtitute the bodies $\frac{A \times S A^2}{S D^2} + \frac{B \times S B}{S D^2} + \frac{C \times SC^2}{S D^2}$, theſe being collected into the points a, b, and c reſpectively: the moving force in this caſe is P; the maſs moved $= \frac{A \times S A^2}{S D^2} + \frac{B \times S B^2}{S D^2} + \frac{S \times S C^2}{S D^2}$; and conſequently the force which accelerates D is that part of the accelerating force of gravity which is expreſſed by the fraction $\frac{P}{A \times \frac{S A^2}{S D^2} + B \times \frac{S B^2}{S D^2} + C \times \frac{S C^2}{S D^2}} = \frac{S D^2 \times P}{A \times S A^2 + B \times S B^2 + C \times S C^2}$.

Cor. 4.—The velocity of the point D is uniformly accelerated, becauſe the force above determined is invariable; it

it follows alſo that the angular velocity of the ſyſtem is uniformly accelerated, becauſe the abſolute velocity of any point at a given diſtance from the axis of motion is as the angular velocity of that ſyſtem, and conſequently of the whole ſyſtem.

Cor. 5.—It is manifeſt that it is of no conſequence whether the bodies A, B, C, &c. revolve in the ſame or in different planes, if their diſtances from the axes S A, S B, S C, are the ſame, theſe diſtances being eſtimated by lines drawn through A, B, and C perpendicular to the common axis of motion; if, therefore, they ſhould be ſituated in various planes, they may be referred to one given plane perpendicular to the axis.

Cor. 6.—It is obvious alſo, that changing the poſition of the bodies A, B, and C in the ſame plane will not affect the force which accelerates the ſyſtem, provided their reſpective diſtances from the axis of motion do not alter: thus, with the centre S, and diſtances S B, S C, let the arcs of circles be deſcribed; if B is transferred to *b*, or C to *c*, the moving force, which acts on theſe bodies reſpectively, will not be altered, and conſequently the maſſes moved being likewiſe conſtant, the accelerating force will be the ſame.

Cor. 7.—Alſo the propoſitions concerning rotation will be equally true, whatever be the forces by which the angular motion is generated, provided it be conſtant; or if variable, ſhould its action be conſidered for an evaneſcent particle of time only.

Cor. 8.—In theſe propoſitions the angular motion is ſuppoſed to be communicated by the action of a force applied at a ſingle point only, at an invariable diſtance from the axis. Thus, ſuppoſe a revolving ſyſtem to conſiſt of the bodies A, B, C of evaneſcent magnitudes, and equal to each other in quantity.—Let a weight P equal to A, B, or C be applied by means of a line, going round a wheel D H, ſo as to communicate motion to the ſyſtem during its deſcent. Moreover, let S D = 1, S A = 2, S B = 3, and S C = 4, and let it be required to aſſign the force which accelerates the deſcent of the weight P.

Here referring to the rule, we have the force required $= \frac{S D^2 \times P}{A \times A S^2 + B \times B S^2 + C \times C S^2} = \frac{1}{4 + 9 + 16} = \frac{1}{29}$, which is the true accelerating force, when the moving force is void of inertia; but in the preſent caſe the force P acts not only as a moving force, but as part of the maſs moved, and as P moves with the ſame velocity as the point D, the effects of its inertia will be eſtimated by ſuppoſing a maſs of matter = P to be collected into the point D; here then the moving force being P, and the maſs moved $P \times \frac{S D^2}{S D^2} + A \times \frac{A S^2}{S D^2} + B \times \frac{B S^2}{S D^2} + C \times \frac{C S^2}{S D^2}$ the force which accelerates the deſcent of P will be $\frac{S D^2 \times P}{P \times S D^2 + A \times A S^2 + B \times S B^2 + C \times S C^2} = \frac{1}{30}$, the line and parts of the wheel not being taken into account. It follows, therefore, that the weight will deſcend from reſt by the force of this acceleration through $\frac{16\frac{1}{12}}{30}$ parts of a foot in a ſecond; and in other different times of deſcent the ſpaces will be varied in a direct duplicate ratio of the times, becauſe the accelerating force is conſtant.

Moreover, the velocity acquired by the weight P in a given time, or through a given ſpace, will be determined by the uſual laws of falling bodies.

Thus putting $\frac{P \times S D^2}{P \times S D^2 + A \times A S^2 + B \times B S^2 + C \times C S^2} = F$, $l = 193$ inches, $f =$ the ſpace deſcribed by P from reſt, the velocity acquired by P will be $\sqrt{4 l F f}$ inches in a ſecond, and in the ſame manner, having given any two of the four quantities, *i. e.* the accelerating force, the ſpace deſcribed from reſt, the time of deſcription, and the velocity acquired, the other two may be determined.

In a ſyſtem of bodies A, B, C, (*fig.* 3.) revolving round an axis which paſſes through S; having given the quantities of matter contained in A, B, C, and the diſtances S A, S B, S C, it is required to determine S R, the diſtance of the centre of gyration from the axis of motion.

Let any force P be applied to turn the ſyſtem at any given diſtance from the axis S D. If the force which accelerates a given point D be the ſame in any two caſes, the abſolute velocity of that point, generated in a given time, muſt be the ſame, and conſequently the angular velocity generated in the ſyſtem equal in both caſes, the force which accelerates the point $D = \frac{P \times S D^2}{A \times A S^2 + B \times B S^2 + C \times C S^2}$; now let A + B + C coincide with R, and the force which accelerates D will be $\frac{P \times S D^2}{A + B + C \times S R^2}$: theſe forces muſt be equal by the hypotheſis; making, therefore, $\frac{P \times S D^2}{A \times A S^2 + B \times B S^2 + C \times C S^2} = \frac{P \times S D^2}{A + B + C \times S R^2}$ we ſhall have $S R^2 = \frac{A \times A S^2 + B \times B S^2 + C \times C S^2}{A + B + C}$, and the diſtance of the centre of gyration required $= \sqrt{\frac{A \times A S^2 + B \times B S^2 + C \times C S^2}{A + B + C}}$.

Cor. 1.—Let A + B + C = W, and ſince $A \times A S^2 + B \times B S^2 + C \times C S^2 = S R^2 \times W$, it follows, that $S R^2 = S O \times S G$: wherefore the diſtance of the centre of gyration is a mean proportional between the diſtances of the centres of gravity and oſcillation from the axis of motion.

Cor. 2.—Every thing remaining, the angular velocity generated in a ſyſtem will be the ſame, whether the maſs W is placed at the diſtance $S R = \sqrt{S O \times S G}$, or whether the maſs $\frac{W \times S R^2}{S D^2}$ is placed at the diſtance S D.

Cor. 3.—Let the ſyſtem revolve in the ſame place as before, and round an axis which paſſes through the centre of gravity, and let $G Q = \sqrt{\frac{A \times G A^2 + B \times G B + C \times G C^2 \&c.}{A + B + C}}$, being the diſtance of the centre of gyration, from the axis of motion; from the propoſition it appears, that $G Q^2 = S G \times G O$.

Cor. 4.—Let A B C D repreſent any pendulous body, moveable a round an axis of motion H I, which paſſes through S, and let any impact be impreſſed on the point D, (while the pendulum is at reſt), in an horizontal direction, and perpendicular to the vertical plane A B C D.

To find the angular velocity which is communicated to the pendulum by the impact, let the weight of the pendulum be W, let G be the centre of gravity, O the centre of oſcillation, and R the centre of gyration; then let a weight be aſſumed, which is to W as $S R^2$, or $S O \times S G$, to $S D^2$;

this

this weight $= \frac{W \times SO \times SG}{SD^2}$ being collected into the point D, the ſame angular velocity will be generated in the ſyſtem, as when the pendulum is of the prior form, every thing elſe being the ſame.

Let S I K (*fig.* 4.) repreſent the plane in which any irregular body or ſyſtem of bodies revolves round an axis of motion, paſſing through the centre of gravity G: having given the weight of the ſyſtem, and the point D, to which a given force is applied, it is required to aſſign the diſtance of the centre of gyration from the axis of motion.

Let G be the common centre of gravity of the ſyſtem; and ſuppoſe the whole to be referred to the plane S I K; let the ſyſtem revolve in this plane round a fixed horizontal axis, which paſſes through G: through G draw any line S G *o*, and with the centre G, and any diſtance G D, draw the circle S D I K, and ſuppoſe all matter which is coincident with the circumference S I K juſt deſcribed to be collected into A: in like manner imagine all the matter contained in other concentric circles to be collected into the correſponding points in the line G *o*; let *g* be the centre of gravity of the matter contained in this line, and let *o* be the centre of oſcillation; then if a weight $= \frac{W \times So + Sg}{GD^2}$ were collected into the circumference S I K, or any point of it D, the other parts of the ſyſtem being removed, the point D would be accelerated in the ſame manner as when the ſyſtem itſelf is acted upon by the ſame force applied at the ſame diſtance from the axis. In this caſe, the force which accelerates $D = \frac{SD^2 \times P}{Sg \times So \times W}$, or if the inertia of P is conſidered, the force $= \frac{SD^2 P}{P \times SD^2 + Sg \times So \times W}$; but ſince the figure of the ſyſtem is not geometrical, the quantity $W \times \frac{Sg \times So}{SD^2}$, or the equivalent weight, cannot be eſtimated by theory; it may be determined by experiment in the following manner:

Let a weight, P, be applied to communicate motion to the ſyſtem by means of a very ſlender and flexible line going round the wheel S D K, through the centre of which the axis paſſes. Let this weight deſcend from reſt through any convenient ſpace *s* inches, and let the obſerved time of its deſcent be *t* ſeconds; then if *l* be the ſpace through which bodies deſcend freely by gravity in one ſecond, the equivalent weight ſought $= \frac{W \times Sg \times Sq}{SD^2} = \frac{P \times t^2 l}{s} -$ P. Let this weight = Q, and we ſhall obtain the ſum of each particle multiplied into the ſquare of its diſtance from the axis of motion; and conſequently the diſtance of the centre of gyration from the ſame axis: for ſince Q : W :: $Gg \times Go : GD^2$, we have $A \times GA^2 + B \times GB^2 + C \times GC^2$, &c. $= GD^2 \times Q = Go \times Gg \times W$, and ſince $Go \times Gg = GR^2$, it follows that the diſtance of the centre of gyration from the axis, or $GR = GD \times \sqrt{\frac{Q}{W}}$.

This having been once determined, the force which accelerates any point of the ſyſtem in other caſes, at whatever diſtance the moving force be applied, will be known: for the angular velocity of the ſyſtem will always be the ſame as if the whole were collected into the centre of gyration.

An experimental method is alſo delivered by Bernouilli, and long ago tranſcribed: a demonſtration of it may be here inſerted as a further illuſtration of the principles of rotation. In any irregular figure referred to the plane S I K, (*fig.* 4.) let G be the centre of gravity, D the point to which a moving force is applied to turn the ſyſtem round an axis which is perpendicular to the plane S I K: with the centre G, and diſtance G D, deſcribe a circle S L M, then taking any point in the circumference S, let the ſyſtem vibrate in the plane S I K perpendicular to the axis which paſſes through S, and let O be the centre of oſcillation of the ſyſtem ſo vibrating; then let $GO = b$, $SG = GD = d$, the weight of the ſyſtem $= W$, and the moving force $= p$: the force which accelerates $D = \frac{p \times GS}{p \times GS \times w \times GO} = \frac{p d}{p d \times w b}$: the demonſtration of this rule follows immediately from the preceding principles: for ſince the centre of gravity is G, and of oſcillation O, it follows that $SG \times GO \times w = A \times AG^2 + B \times BG^2 + C \times GC^2$, or the ſum of all the products which are formed by multiplying each particle in the ſyſtem into the ſquare of its diſtances from the axis, when that axis paſſes through the common centre of gravity; wherefore $SG \times GO \times bd = \frac{A \times AG^2 + B \times BG^2 + C \times CG^2}{w} =$ the ſquare of the diſtance of the centre of gyration from the axis, when the ſyſtem revolves round G; let the maſs *w* be collected into the centre of gyration, at the diſtance $\sqrt{bd}$ from the axis; then will the communication of motion be the ſame as if the equivalent weight $w \times \frac{bd}{d}$ were collected in the point D, the other parts of the ſyſtem being removed: here the force which communicates motion to the point D is *p*, the maſs moved $p \times \frac{bw}{d}$, and the force which accelerates $D = \frac{p}{p + \frac{bw}{d}} = \frac{pd}{pd \times bw}$.

The diſtance S O is obtained practically thus: ſuppoſe that the ſyſtem performed *n* leaſt vibrations in *t* ſeconds; if $l = 193$ inches, $p = 3.14159$, &c. $SO = \frac{2 l t^2}{n^2 p^2}$ the length required.

GYRFALCON, in *Ornithology*, the name of a large and fierce ſpecies of falcon, called in Engliſh the *jerfalcon*. Its name is a compound of the German *gyr*, which ſignifies a *vultur*, and *falco*, the *falcon*. See Falco *Candicans*, and Gerfalcon.

Gyrfalcon, *Brown*. See Falco *Gyrfalco*.

GYRINOPS, in *Botany*, from γυρινος, a *tadpole*, and ὀψις, an *aſpect* or *appearance*, apparently becauſe its ſeeds and their ſtalks reſemble thoſe animals. If ſo, the word ought rather to have been *Gyrinopſis*. We can find no reaſon to trace it directly from ὀψ, the *eye*.

The above name is given by Gærtner, v. 2. 276. t. 140, to a fruit from Ceylon, called in that country *Walla*, which he deſcribed from the muſeum at Leyden. It conſiſts of a coriaceous, obovate, compreſſed, ſtalked capſule, not an inch long, and about half an inch broad, marked with a longitudinal furrow on each ſide, and with ſwellings where the ſeeds are ſituated. The edge is ſlightly thickened all round; the apex tipped with a little hooked point. The inſide is divided into two cells, by a longitudinal partition, contrary to the valves, and originating from the centre of one on both

both of them. In each cell is a ſolitary ſeed, of an ovate pointed figure, convex on one ſide, flat on the other, ſupported by a white, fungous ſtalk, tapering downwards, ſomewhat triangular, half as long again as the ſeed.

Gærtner offers nothing concerning the natural order, or affinities, of this plant. A minute bell-ſhaped calyx, or rather perhaps baſe of a calyx, remains at the bottom of the ſtalk which elevates the capſule, and this is all that is known of the flower. It is enough to prove the plant not of the cruciform or *Tetradynamia* claſs, and more reſembles the calyx of the *Papilionaceæ;* but the partition, as well as the inſertion of the ſeeds, defy all analogies among the latter.

GYRINUS, in *Entomology*, a genus of Coleoptera, the antennæ of which are elevated and rigid; jaws horny, ſingle-toothed, and ſharp-pointed; eyes four, two of which are placed above and two beneath; thorax and wing-caſes margined, the latter ſhorter than the body; legs formed for ſwimming.

The gyrinus at the firſt view appears ſo nearly allied to the dytiſcus, that Scopoli has united them in the ſame genus; the moſt eſſential difference conſiſts in the number of the eyes, the dytiſci having only two; and alſo in the ſtructure of the antennæ, thoſe of the dytiſcus tribe having the elevated part of thoſe organs perfoliated, and not being rigid or ſtiff, as in that of gyrinus.

The inſects of this genus are of the aquatic kind, and are frequently met with in ſtanding waters, where they are eaſily diſtinguiſhed by their ſhining blackneſs, and the ſwift and circular direction of their motions in ſwimming. They are often obſerved on the ſurface of the water on which they run, and form circles with amazing celerity; and when diſturbed, immediately plunge to the bottom, drawing after them a brilliant bubble, reſembling a globule of quick-ſilver. The larvæ are unknown, but are generally believed to reſemble thoſe of the dytiſcus. In England theſe beetles are ſometimes called water fleas.

Species.

Natator. Oval, ſub-ſtriated, and black. Geoff. *Dytiſcus natator*, Linn. Fn. Suec. *Pulex aquaticus*, Merret. *Gyrinus pygolampes*, Modeer.

Inhabits Europe, in ſtagnant pools.

Bicolor. Black, beneath ferruginous; poſterior legs compreſſed. Fabr.

Larger than the laſt, and inhabits Sweden.

Auſtralis. Somewhat ſtriated and greeniſh; wing-caſes abbreviated, and ſingle-toothed. Modeer. Fabr. &c.

Found in the waters of New Holland; wing-caſes truncated, and the four poſterior legs ferruginous.

Americanus. Smooth, black, and opaque; four poſterior legs ſhort, and teſtaceous. Fabr.

Native of South America, and reſembles natator, but is twice the ſize.

Micans. Smooth, olive, poliſhed; wing-caſes with a gloſſy black band behind. Fabr.

The largeſt of its genus, and inhabits Guinea; the body olive, tinged with coppery and ſilvery gloſſes; beneath black; poſterior legs teſtaceous.

Spinosus. Black, poliſhed; thorax and wing-caſes edged with yellow, the wing-caſes ſpinous. Fabr.

Native of Coromandel. Wing-caſes with two long ſharp ſpines; body beneath ferruginous; tail black. Fabr.

Striatus. Green, poliſhed; edges of the thorax and wing-caſes pale, the laſt ſtriated. Thunberg.

Inhabits Barbary. The antennæ are green; head braſſy-green; front ſometimes violet; wing-caſes ſtriped with green and violet, and rounded at the end; legs pale.

Grossus. Beneath black; above paler, and very ſmooth; wing-caſes rounded at the tip. Modeer.

Found in the clear waters of the Cape of Good Hope.

Formosus. Beneath black; breaſt, ſternum, and legs ferruginous; above braſſy-green; tranſverſe line on the lip, two ſpots on the front, tranſverſe interrupted line on the thorax, and ſtreaks on the wing-caſes golden-red. Modeer.

Native of the clear waters of the Cape. Modeer deſcribes a variety half the ſize, in which the golden-hue does not appear.

Orientalis. Beneath pale ferruginous, above braſſy-black; wing-caſes each ſide compreſſed; wing-caſes ſtriated, bronzed, four-toothed behind. Modeer.

Body roundiſh; wing-caſes as long as the abdomen. Native place unknown.

Viola aquatica. Beneath pale ferruginous; above black, with mouſe-coloured down. Modeer. *Viola aquatica*, Aldrovandus, &c.

Inhabits ſalt-waters.

Kirbii. Above braſſy-black; beneath yellow. Marſh.

Length one line and three quarters; wing-caſes ſtriated; legs as well as body beneath yellow. Native of Britain.

Modeeri. Above ſmooth, black, and ſomewhat downy; beneath pale ferruginous; poſterior legs compreſſed. Marſh.

Inhabits Britain. Length three lines.

Elongatus. Black, opaque, and elongated; wing-caſes ſtriated with dots. Marſh.

Length three lines, and inhabits Britain.

Gyrinus, in *Zoology*, a name uſed for a ſpecies of the *Cereari*, and alſo of the *Murex*.

GYRLE, among *Sportſmen*. See Girle.

GYROCARPUS, in *Botany*, from γυρος, *to turn round and round*, and καρπος, *fruit;* becauſe the winged fruit, when thrown up into the air, deſcends ſlowly with a twirling motion. Jacquin, the author of the name, tells us the children at Carthagena, where the tree grows, amuſe themſelves with it as a kind of ſport. Jacq. Amer. 282 Roxb. Corom. v. 1. 1. Lamarck. Dict. v. 3. 65. Illuſtr. t. 850. Gærtn. t. 97. Brown. Prod. Nov. Holl. v. 1. 404.—Claſs and order, *Polygamia Monoecia*. Nat. Ord. doubtful. Mr. Brown places it at the end of his *Laurinæ* (*Lauri*, Juſſ.), as more akin to that order, than to a new one in which *Combretum*, *Terminalia*, &c. are included. We ſhould rather think it moſt allied to the latter.

Gen. Ch. United flowers, *Cal.* Perianth ſuperior, in four deep ſegments; the two outermoſt oppoſite ones ſmall, obtuſe, deciduous; two innermoſt larger, erect, dilated, three-toothed, permanent, finally much enlarged. *Cor.* none. *Stam.* Filaments four, thread-ſhaped, ſpreading, equal, rather exceeding the calyx, oppoſite to its ſegments, with four club-ſhaped, rather ſhorter, barren filaments, alternate with them; anthers quadrangular, opening at each ſide by an oval valve from the bottom to the top. *Piſt.* Germen inferior, ovate, angular; "ſtyle very ſhort; ſtigma capitate, oblique." *Brown. Peric.* Drupa dry, ovate, octangular, of one cell, with a coriaceous coat, crowned with the two enlarged, upright, wing-like ſegments of the calyx, above four times its own length. *Seed* ſolitary, obovate; albumen none; embryo inverted; cotyledons ſtalked, convoluted round the embryo; "plumula of two leaves." *Brown.*

Male, *Cal.* Perianth of five deep, ovate, equal ſegments. *Stam.* as in the united flowers, with barren filaments. *Piſt.* none.

Eſſ. Ch. United flowers; Calyx in four ſegments; two oppoſite ones permanent, enlarged. Corolla none. Stamens four

four or more, with alternate, barren, club-ſhaped filaments. Drupa of one cell, crowned with two wings.

Male; Calyx of five equal ſegments. Stamens as in the other flowers. Piſtil none.

Obſ. Gærtner was induced to conſider this genus, of which he knew nothing but the fruit, as akin to the Maple tribe; the wings, however, being formed of the calyx, and not originally a part of the germen, are very different from thoſe of *Acer*, *Banniſteria*, *Triopteris*, &c. Mr. Brown deſcribes the ſegments of the calyx as varying from four to eight, and conſequently the number of ſtamens is variable. This author, moreover, does not mention the difference between the perianths of the two different kinds of flowers, indicated and delineated in Dr. Roxburgh's work, and which is of the more conſequence, as, if it exiſts, the genus truly belongs to the *Polygamia* claſs, for that reaſon; but if otherwiſe, to *Tetrandria Monogynia*.

The ſpecies are difficult to determine. The late excellent Mr. Dryander, editor of Roxburgh's work, conſidered his plant as the ſame with Jacquin's. Willdenow it ſeems has ſeparated them, but we have not yet obtained this volume of his valuable book. Mr. Brown adopts this meaſure, though he totally rejects Willdenow's ſpecific diſtinctions, nor does he offer any others. We ſhall attempt to define them ſo far as to affix the ſynonyms to each.

1. G. *americanus*; Jacq. Amer. 282. t. 178. f. 80. Lamarck. Dict. v. 3. 65.—Leaves ſlightly heart-ſhaped, ſmooth? deeply three-lobed or undivided. Fruit tranſverſely corrugated.—Native of woods in Carthagena, South America, where it grows to a tall, elegant, branching *tree*. The *leaves* are ſcattered on long ſtalks, and are about a foot in length and as much in breadth, ſhining, cut half way down into three ovate acute lobes, with a rib to each; the margins entire. The ſame tree ſometimes bears undivided ovate leaves. Jacquin ſaw no *flowers*, but the *fruit* grows in looſe terminal bunches, and is dry, ovate, obtuſe, furrowed lengthwiſe, and tranſverſely rugoſe, crowned with two equal, obtuſe, flat, ſtriated, ſhining wings, between two and three inches long. We are poſſeſſed of one fruit only, communicated by Juſſieu as the plant of Jacquin, and having been obtained doubtleſs from America, we preſume it muſt be right.

2. G. *aſiaticus*. (G. Jacquini; Gærtn. v. 1. 92? Roxb. Corom. t. 1. Afrag; Le Brun Voy. v. 2. 257. fig.)—Leaves deeply heart-ſhaped, undivided, or ſlightly lobed; downy beneath. Fruit even.—Gathered by Kœnig and Roxburgh in mountainous parts of Coromandel, where it is called by the natives *Tanucoo*, and by the Engliſh Cattamaran-wood tree, the light white wood being excellent for cattamarans or rafts. The *tree* is very large, ſhedding its leaves towards the end of the rainy ſeaſon, and flowering during the ſucceeding cold one, juſt before freſh foliage comes forth. The *bark* is ſmooth, greyiſh. *Branches* thinly ſpreading. *Leaves* crowded about their extremities, ſtalked, broad-heart-ſhaped, acute, undivided, or with one or two ſlight ſhallow lobes, entire, ribbed, veiny; ſmooth above; downy beneath; furniſhed with two depreſſions on the upper ſide at their baſe. *Panicles* cluſtered, terminal, forked, many-flowered, ſhorter than the leaves; the male flowers terminal, cluſtered; the united ones ſolitary in the forks below them; all ſmall and yellowiſh. *Fruit* the ſize of a filberd, furrowed, but apparently not tranſverſely corrugated, at leaſt ſo Roxburgh delineates it, though he deſcribes it *wrinkled*, but this term may apply to the longitudinal furrows. Gærtner's figure, taken moſt probably from one of Kœnig's ſpecimens at ſir Joſeph Banks's, agrees with Roxburgh's in this reſpect, not with Jacquin's, nor with our American ſpecimen. Thoſe who have more ample materials muſt decide how far this is a permanent ſpecific diſtinction.

3. G. *ſphenopterus*. Brown. Prod. n. 1.—Leaves heart-ſhaped, downy on both ſides, grey beneath; the floral ones moſtly undivided. Wings of the fruit obtuſe, entire, or divided.—Gathered by Mr. Brown in the tropical of New Holland. The floral *leaves* are moſtly undivided, rarely two or three-lobed. Their *footſtalks* are ſhorter than the common flower-ſtalk, as in the preceding. Wings of the *fruit* obovato-oblong, obtuſe, occaſionally divided; that is, as we preſume, when the calyx has a ſuperabundant number of ſegments.

4. G. *rugoſus*. Ibid. n. 2.—"Floral leaves ſomewhat heart-ſhaped, with three angular lobes; rugged and nearly naked above; downy and ſoft beneath; their lobes pointed, ſeparated by very broad ſinuſes."—Diſcovered by Mr. Brown in the ſame country with the laſt, but he did not meet with the fruit. The common *flower-ſtalk* is, in this alſo, longer than the *footſtalks*, if there be no miſtake in this part of Mr. Brown's definition, which we are led to ſuſpect, merely becauſe the ſame character obtains in all the foregoing, and therefore cannot properly make a part of the ſpecific difference of any one. Perhaps in the laſt *longiore* was accidentally written for *breviore*.

GYROGONITES, in *Mineralogy*, an indeterminable foſſil, ſcarcely of the ſize of the head of a pin, and of a white colour; found diſſeminated in the ſubſtance of a hard ſiliceous ſtone (called mill-ſtone), in the neighbourhood of Paris. Lamarck has eſtabliſhed it as a genus, the character of which is taken from its ſpheric form, and from its ſurface being horizontally all around ſtriated by parallel ſpiral grooves carinated at the borders.

Boſc obſerves that this foſſil need only be ſeen in its place, to convince the obſerver that it is nothing but the inner mould of a deſtroyed ſhell; that, conſequently, it cannot with propriety be taken for the type of a new genus; and that the caſt, to which the above characters are likewiſe applicable, furniſhes no particular data to guide us with regard to its determination. We cannot, therefore, ſatisfy our curioſity with reſpect to the nature of this foſſil.

GYROLA, in *Ornithology*. See TANAGRA *Gyrola*.

GYROMANCY, GYROMANTIA, a kind of divination, performed by walking round, or in a circle.

The word is compounded of the Greek γυρος, *circle*, and μαντια, *divination*.

GYRON. See GIRON.

GYROPHORA, in *Botany*, ſo named by profeſſor Acharius, from γυρος, *a circle*, and φερω, *to bear*, in alluſion to the concentric circles, more or leſs numerous or complicated, obſervable in the diſk of the receptacles or ſhields. Ach. Meth. 100. Sm. Engl. Bot. v. 29. 2066. (Umbilicaria; Hoffm. Pl. Lich. v. 1. 8. t. 2. Lichen; Linn. Gen. 566. Schreb. 767. Juſſ. 7. Claſs and order, *Cryptogamia Algæ*. Nat. Ord. *Lichenes*.

Gen. Ch. *Frond* leafy, membranous and flexible when dry, rigid and brittle when wet, peltate, fixed by central roots, more or leſs orbicular, ſimple or luxuriantly compound, the margin wavy, or lobed, jagged or notched, rarely entire. *Tubercles*, or *Tricæ*, either ſeſſile, or ſlightly elevated by a ſhort ſtalk, ſcattered over the upper ſurface, either flat, or more or leſs convex, entirely black, compoſed of concentric plaits, ſometimes tranſverſely folded, on the upper ſide or diſk, at length ſeparating irregularly. *Seeds* lodged on the inſide of the plaits.

Eſſ. Ch. Tubercles ſeſſile on a peltate frond, black, with a plaited

a plaited contorted diſk, in whoſe clefts the ſeeds are lodged.

This is one of the moſt diſtinct and moſt natural genera that have been ſeparated from *Lichen*. Examples of it may be ſeen in Engl. Bot. t. 1282, 1283, 2066, 522, and 931. The ſpecies in Acharius's Methodus are 15, beſides his *Lecidea puſtulata*, (*Lichen puſtulatus*, Linn.) which we truſt will ſufficiently appear, by the plate in Engl. Bot. t. 1283, to belong to *Gyrophora*. If it did not, the whole genus would be overſet; for ſo cloſely is that plant allied to the other ſpecies, in their very peculiar habit, that no ſcientific principles can diſjoin them. They all grow on expoſed alpine rocks, chiefly on granite, or volcanic ſtones. The vitrified forts in the Highlands of Scotland, as on Tomtarſin hill, produce ſome of them, eſpecially *G. eroſa*.

To diſcriminate the ſpecies and their ſynonyms is, in many caſes, very difficult, and the whole genus wants a thorough inveſtigation, which can be undertaken with effect by thoſe only who have opportunities of tracing their different appearances on their native rocks. By ſuch an inveſtigation ſome ſuppoſed ſpecies, extremely different in ſize and luxuriance, will be found to run into each other, and the fringed margin of others, however curious and remarkable, will prove occaſionally evaneſcent.

GYROVAGI, in *Eccleſiaſtical Writers*, monks, who leaving their monaſteries, under pretence of piety, wandered about from one religious houſe to another.

The ſame appellation was alſo given to prieſts who left their pariſhes.

GYRT, in *Geography*, a ſea-port town of Sweden, in Eaſt Gothland; 30 miles S.S.E. of Nordkioping.

GYSSENS, a town of the iſland of Borneo, on the E. coaſt. N. lat. 1°. E. long. 117°.

GYSSONE, a town of the iſland of Corſica; 29 miles S. of Corte.

GYTHIUM, Colo-Kitia, in *Ancient Geography*, a port of Laconia, in the Laconic gulf, at the mouth of a ſmall river. Livy (l. xxxiv. c. 29.) ſpeaking of the war in Greece occaſioned by T. Quintius Flaminius, B.C. 195, deſcribes it as very ſtrong and well-peopled.

GYTHOW, or Jethow, in *Geography*, a ſmall iſland in the Engliſh channel, between the iſland of Guernſey and the greater Sark.

GYULA, or Julia, a town of Hungary, ſituated on an iſland, in the river Kores, with a caſtle; 50 miles N.N.W. of Temeſvar.

GYZANTES, in *Ancient Geography*, a people of Africa, in the weſtern part of Libya, near the Zauæci, who cultivated bees and made a great quantity of honey. Herodotus ſays, that they painted themſelves with vermilion, and ate apes, which were abundant on their mountains.

GZAT, in *Geography*, a town of Ruſſia, in the government of Smolenſk; 88 miles E.N.E. of Smolenſk. N. lat. 55° 34′. E. long. 35° 14′.

GZINDER, a town of Pruſſian Pomerelia; 10 miles E. of Dantzic.

H.

H Is the eighth letter of our alphabet, and the ſixth conſonant.

Varro, De Re Ruſtica, lib. iii. cap. 1. calls the *h*, *afflatus*; and Martianus Capella ſays it is pronounced only by a gentle contraction of the trachea. Hence it has been diſputed, whether or not the *h* be a real letter.

Some will only have it to be an aſpiration, or ſpirit, becauſe its ſound is ſo weak. And accordingly the Greeks, of later ages at leaſt, do not place it in the line with the other letters, but put it over the head of the letter which follows it; though it ſhould ſeem they anciently wrote it in the ſame line with the reſt.

The Latin grammarians, as they were religious imitators of the Greeks, have, on their authority, generally diſallowed the *h* as a letter; and the moderns have, in this reſpect, followed the Latins, urging, that it is ſounded only by a ſtrong emiſſion of the breath, without any conformation of the organs of ſpeech, and therefore that it is no letter. However, others maintain that the *h*, like all other aſpirates, from the time it is aſpirated, and for this very reaſon that it is aſpirated, is not only a letter, but a real conſonant; it being a motion, or effort of the larynx, to modify the ſound of the vowel that follows; as is evident in the words *heaven*, *health*, *hero*, &c. where the vowel *e* is differently modified from what it is in the words *endive*, *eating*, *elect*, &c. and ſuch modification is all that is eſſential to a conſonant. They add, that the *h* is either a letter, or *ſ* and *z* are none; thoſe being no more than hiſſing aſpirations; and that they who exclude the *h* from among the letters, as conceiving it only a mark of aſpiration, might as well exclude the labial conſonants *b* and *p*, and ſay they are only marks of certain motions of the lips, &c. Hence they conclude that the *h* is a letter, and a conſonant of the guttural kind, *i. e.* a conſonant, to the pronunciation whereof the throat concurs, in a particular manner, more than in any other of the organs of voice.

It is true, in many words beginning with *h*, the aſpiration is very weak, and almoſt inſenſible; the *h* in thoſe caſes not doing its office: but it does not ceaſe to be a conſonant

on that ground, more than the various other conſonants, which we write but do not pronounce; as the *k* in *quick*, &c. and ſeveral other letters, particularly in the Hebrew, French, &c. Nor does it ceaſe to be a conſonant, becauſe it does not hinder the eliſion of the foregoing vowel, when another vowel follows in the ſubſequent word: for then *m* would undergo the ſame diſqualification.

M. Menage diſtinguiſhes two kinds of *h*; the one an aſpirate, which he allows to be a conſonant, the other a mute, which he conſiders as a vowel. Now, it is certain, the aſpirated *h* is a conſonant; but the mute *h* is no vowel, as having no peculiar or proper ſound diſtinct from that of the vowel, or diphthong, immediately following it.

When the *h* is preceded by a *c*, the two letters together have frequently the ſound of the Hebrew ץ, with a point over the right horn: as in *charity*, &c.

In moſt words derived from the Greek, and beginning in that language with the letter χ, the *ch*, which begins them in Engliſh, has generally the ſound of a *k*, as in *echo*, *chorus*, &c. though it is ſometimes ſoftened a little, as in *Cherſoneſus*, &c.

After a *p*, the *h* is always pronounced, together with the *p*, like an *f*; as in *phraſes*, *Philiſtines*, *phlegm*, *phlebotomy*, *philoſophy*, *Phoceans*, &c. Moſt words of this claſs are either proper names, or terms of art, borrowed from the Greek, or the Oriental languages; and written in Greek with a φ, and with a פ in the others.

This letter is pronounced by a ſtrong emiſſion of the breath between the lips cloſing by a gentle motion of the lower jaw to the upper, and the tongue nearly approaching the palate. Our H, which is the ſame with that of the Romans, moſt probably derived its figure from the Hebrew ח.

The *h* in Engliſh is ſcarcely ever mute at the beginning of a word, or where it immediately precedes a vowel, as *houſe*, *behaviour*, &c. It is always ſilent after *r*, as *rhetoric*, *rheum*, *rhubarb*, &c. Where it is followed by a conſonant, it has no ſound, according to the preſent pronunciation. H final, preceded by a vowel, is always ſilent; as *ah! oh! Meſſiah*, &c. Mr. Murray, in his much approved Engliſh grammar, obſerves, that from the faintneſs of the ſound of this letter, in many words, and its total ſilence in others, added to the negligence of tutors, and the inattention of pupils, it has happened, that many perſons have become almoſt incapable of acquiring its juſt and full pronunciation. It is, therefore, incumbent on teachers to be particularly careful to inculcate a clear and diſtinct utterance of this ſound.

In ancient authors we frequently meet with *h* put inſtead of *f*, as *haba* for *faba*; but this is principally obſervable in the Spaniſh tongue, where moſt of the words borrowed from the Latin, beginning with an *f*, take the *h* in lieu of it: as *hablar*, for *fabulari*; *habo*, for *fabus*; *hado*, for *fatum*. For the relation which *h* has to the Æolic digamma, ſee the letter F.

The aſpirate or ſharp accent of the Greeks, which is the ſame with our *h*, is alſo frequently changed in the Latin for an *s*; ἁλς, *ſal*; ἑπτα, *ſeptem*; ἑξ, *ſex*; ἑρπω, *ſerpo*; ἡμισυ, *ſemis*; ὑς, *ſus*, &c. The *h* is alſo uſed for ſome other letters, enumerated at large by Paſſerat, "De Literarum inter ſe Cognatione & Permutatione."

Anciently the *h* was put for *ch*; thus *Chlodoveus* was formed *Hludovicus*, as it is read on all the coins of the ninth and tenth centuries; and it was on this account that they wrote *Hludovicus* with an *h*. In courſe of time, the ſound of the *h* being much weakened, or entirely ſuppreſſed, the *h* was dropt, and the word was written *Ludovicus*. In like manner we read *Hlotaire*, *Hlovis*, &c. F. Lobineau will have this difference to have ariſen from the differences in the pronunciation. Such, ſays he, as could not pronounce the guttural, with which theſe two words begin, ſubſtituted a *c* for it; and they who pronounced it ſo, wrote it after the ſame manner: but ſuch as were accuſtomed to pronounce the guttural, wrote it likewiſe. He might have added, that ſuch as could not pronounce it, at length abſolutely rejected it, and both wrote and ſpoke *Louis*, *Lotaire*, &c. Some learned men have conjectured, that the *h* ſhould have been detached from the name; and that it ſignified lord, from the Latin *herus*, or the German *herr*: much as the D, which the Spaniards prefix to their proper names, as *D. Phelipe*, for Don Philip. But as it is likewiſe found before the names of ſeveral cities, it is more probable the letter was there uſed to denote the rough harſh pronunciation of the ancient Franks.

In reality, the moſt ancient way of writing the names of theſe French kings was not by *h*, but by *ch*; where the *c* ſeems to have ſtood for *koning*, *king*, and the *h* was inſerted to give the *c* a guttural ſound.

The *h* is ſometimes alſo found prefixed to the *c*; as *Hcarolus*, *hcalendæ*, &c. for *Carolus*, *calendæ*, &c.

H, among the *Ancients*, was alſo a numeral letter, ſignifying 200, according to the verſe:

"H eoque ducentos per ſe deſignat habendos."

When a daſh is drawn at the top of the H̄, it ſignified two hundred thouſand. See what has been obſerved on this ſubject under the letter A.

H, as an abbreviation, was ſometimes uſed by the ancients to ſignify *homo*, *hæres*, *hora*, &c.

H, as an aſpirate, being no letter in the Italian language, whence moſt of our *Muſical* terms are derived, furniſhes few initials or abbreviations. It ſometimes, however, is uſed for half-note, and haubois. In German muſic it ſtands for B *quadro*, or B ♮, in oppoſition to B *rotondo*, or B ♭. In Guido's ſcale, the B flat is called B *fa*, and the B ♮, or B natural, B *mi*.

HAA, in *Geography*, a ſmall iſland in the North ſea, near the coaſt of Scotland; 3 miles S.E. of Farout Head. N. lat. 58° 32′. W. long. 4° 28′.

HAACK, a town of Holland, on the N.E. coaſt of the iſland of Walcheren, with a light-houſe near it. N. lat. 51° 38′. E. long. 22° 7′.

HAAG, a town of Bavaria, and capital of a county of the ſame name, ſeated on a hill on the W. ſide of the river Inn; 28 miles E. of Munich.

Haag is alſo the name of ſeveral towns in Auſtria.

HAAL, or Hal, a town of Arabia, in the province of Oman; 15 miles N.W. of Maſcat.

HAANO, one of the iſlands called Hapaee, in the ſouthern Pacific ocean, diſcovered by Capt. Cook in 1777. S. lat. 19° 41′. E. long. 185° 43′.

HAARLEM. See Haerlem.

HAAS, John Matthew, in *Biography*, was born at Augſburg in 1684, where he received the early part of his education, and was ſent to Helmſtadt to ſtudy theology, with an intention of making that the principal purſuit of his life, but having a decided turn for mathematics, he removed to Leipſic, where he purſued the ſciences, properly ſo called, with diligence and great ſucceſs. The firſt attempt as an author was the conſtruction of maps, which obtained for him much applauſe. His principal object in the maps was to exhibit with more accuracy the ſituation of countries at that time but little known. He took his regular degrees, and ſupported himſelf by teaching. His chief work was entitled "Deſcriptio Geographica et Hiſtorica Regni Davidici et Salomonæi, cum Delineatione Syriæ et Egypti,"

Egypti," fol. cum fig. He laboured alſo many years at another work, part of which only was publiſhed, entitled "Prodromus Hiſtoriarum; ſive, Prodromus Theatri ſummorum Imperiorum; hoc eſt, Hiſtoriæ Politicæ univerſalis, potioris, et principalis, &c." An abridgment of this was publiſhed in 1743, with the title of "Hiſtoriæ Univerſalis Politicæ Idæa plane nova et legitima, &c." This was illuſtrated with twenty-eight maps and ſixteen chronological tables. After the author's death, which happened in Sept. 1742, theſe works were publiſhed under the general title of "An hiſtorical Atlas, containing the great Kingdoms and Monarchies, according to ancient Geography." Gen. Biog.

HAATYBUNDER, in *Geography*, a town of Bengal; 38 miles S.E. of Dinagepour.

HABAEL, *Iſlands of*, a cluſter of ſmall iſlands in the Red ſea, near the coaſt of Abyſſinia, anciently called "Alalæi." N. lat. 14° 15'.

HABAKKUK, one of the twelve leſſer prophets, whoſe prophecies are taken into the canon of the Old Teſtament.

The name is written in Hebrew with ח *hheth*; and ſignifies a *wreſtler* or *grappler*. The Greek tranſlators call him *Abbakoum*.

Nothing certain is known concerning the country, or preciſe time in which this prophet lived. It is ſaid, however, that he was of the tribe of Simeon, and a native of Bethzacar; and that, foreſeeing the capture of Jeruſalem by Nebuchadnezzar, he eſcaped to Arabia, where he remained at Oſtracin, near the lake Sirbonis, for ſome time; but that after the city was taken by the Chaldæans, he returned to Judea, and employed himſelf in agriculture. In this country he died and was buried, two years before the end of the captivity, A. M. 3466, B. C. 538. St. Jerom, who makes him to be the ſame with the prophet Habakkuk, to whom the hiſtory of Bel and the Dragon is aſcribed, believes that he was contemporary with Daniel.

The preciſe time is not known when Habakkuk propheſied; but from his predicting the ruin of the Jews by the Chaldæans, it may be concluded that he was contemporary with Jeremiah, and propheſied in the reign of Joſiah. He alſo foretells the conqueſts of Nebuchadnezzar, his metamorphoſis, and death, and the judgments that ſhould befal the Chaldæans, who completed the captivity of the two tribes. He ſpeaks againſt a prince who built with blood and iniquity; probably the king of Tyre; and he accuſes another king with having intoxicated his friend, in order to diſcover his nakedneſs; probably the king of Egypt. His prophecy only conſiſts of three chapters; and cloſes with an admirable ſong, or prayer to God, whoſe majeſty he deſcribes with the utmoſt grandeur and ſublimity of expreſſion. The ſtyle of Habakkuk is poetical, eſpecially in his ode, which, indeed, may be accounted among the moſt perfect ſpecimens of that claſs. Habakkuk, on cloſe examination, will be found to be a great imitator of former poets, but not without new additions of his own; not in the manner of Ezekiel, who is very copious, and who flags behind thoſe whom he imitates, but with much greater brevity, and with no common degree of ſublimity, riſing in this reſpect ſuperior to thoſe whom he imitates, or at leaſt keeping on an equality with them.

HABASCIA, in *Geography*, a town of Arabia, in the country of Yemen; 25 miles E. of Serrain.

HABASEH, a town of Egypt, in the lake Sheib; 48 miles E.N.E of Cairo. N. lat. 30 18'. E. long. 31° 10'.

HABAT. See BENI-*Haſſen*.

HABDALA, or HABDALAH, a Jewiſh ceremony, practiſed among that people every ſabbath-day evening.

The word is Hebrew, and literally ſignifies *ſeparation*: it is formed of בדל, *badal*, *to ſeparate*; the ceremony being looked upon as the diviſion, or parting of the ſabbath from the reſt of the week. It was eſtabliſhed to prevent their being too haſty in ending the ſabbath.

Towards the cloſe of the ſabbath, when the ſtars begin to appear, every maſter of a family lights a torch or flambeau, or at leaſt a lamp with two wicks. A little box of ſpices is then prepared, and a glaſs of wine taken; then ſinging, or rehearſing a prayer, and bleſſing the wine and the ſpices, they all ſmell at them; and, after a few ceremonies performed about the torch, or lamp, they caſt a little of the conſecrated wine into the flame; every body taſtes; and thus they break up, wiſhing each other, not a good night, but a good week.

HABEAS *Corpora Juratorum*, in *Law*, is a writ that lies for bringing in a jury, or ſo many of them as refuſe to come upon the *venire facias*, for the trial of a cauſe brought to iſſue. This is of the ſame nature in the common pleas, as the *diſtringas juratores* in the court of king's bench. This writ commands the ſheriff to have their bodies, or to diſtrain them by their lands and goods, that they may appear upon the day appointed.

HABEAS *Corpus*, a writ, which a man indicted and impriſoned for any crime, or treſpaſs, before the juſtices of peace, or in a court of franchiſe, having offered ſufficient bail, which is refuſed, though the caſe be bailable, may have out of the king's bench, thereby to remove himſelf thither, at his own coſts, to anſwer the cauſe at the bar thereof.

The order, in this caſe, is firſt to procure a *certiorari* out of the chancery, directed to the ſaid juſtices, for removing the indictment into the king's bench; and upon that to procure this writ to the ſheriff, for cauſing his body to be brought at a certain day.

This writ is alſo uſed to bring the body of a perſon into court, who is committed to any gaol, either in criminal or civil cauſes; and a *habeas corpus* will remove a perſon and cauſe from one court and priſon to another. Of this there are various kinds: ſuch as the *habeas corpus ad reſpondendum*, when a man hath a cauſe of action againſt one who is confined by the proceſs of ſome inferior court; in order to remove the priſoner, and charge him with this new action in the courts above (2 Mod. 198.); ſuch is that *ad ſatisfaciendum*, when a priſoner hath had judgment againſt him in an action, and the plaintiff is deſirous to bring him up to ſome ſuperior court to charge him with proceſs of execution. (2 Lilly prac. reg. 4.) Such alſo are thoſe *ad proſequendum*, *teſtificandum*, *deliberandum*, &c. which iſſue when it is neceſſary to remove a priſoner, in order to proſecute or bear teſtimony in any court, or to be tried in the proper juriſdiction wherein the fact was committed. Such is likewiſe the common writ *ad faciendum et recipiendum*, which iſſues out of any of the courts of Weſtminſter-hall, when a perſon is ſued in ſome inferior juriſdiction, and is deſirous to remove the action into the ſuperior court; commanding the inferior judges to produce the body of the defendant, together with the day and cauſe of his caption and detainer, (whence the writ is frequently denominated an *habeas corpus cum cauſa*,) *to do* and *receive* whatſoever the king's court ſhall conſider in that behalf. This is a writ grantable of common right, without any motion in court (2 Mod. 306.); and it inſtantly ſuperſedes all proceedings in the court below. But in order to prevent the ſurreptitious diſcharge of priſoners, it is ordered by ſtatute 1 and 2 P. & M. c. 13. that no *habeas corpus* ſhall iſſue to remove any priſoner out of any gaol, unleſs ſigned by ſome judge of the court out of which it is awarded. And, to avoid vexatious delays by removal of frivolous cauſes, it is enacted by ſtatute 21 Jac. I. c. 23. that, when the

the judge of an inferior court of record is a barriſter of three years ſtanding, no cauſe ſhall be removed from thence by *habeas corpus* or other writ, after iſſue or demurrer deliberately joined: that no cauſe, if once remanded to the inferior court by writ of *procedendo* or otherwiſe, ſhall ever afterwards be again temoved; and that no cauſe ſhall be removed at all, if the debt or damages laid in the declaration do not amount to the ſum of five pounds. But an "expedient" having been found out to elude the latter branch of the ſtatute, by procuring a nominal plaintiff to bring another action for five pounds or upwards, (and then by the courſe of the court the *habeas corpus* removed both actions together,) it is therefore enacted by ſtatute 12 Geo. I. c. 29, that the inferior court may proceed in ſuch actions as are under the value of five pounds, notwithſtanding other actions may be brought againſt the ſame defendant to a greater amount. And by ſtatute 19 Geo. III. c. 70 no cauſe, under the value of ten pounds, ſhall be removed by *habeas corpus*, or otherwiſe, into any ſuperior court, unleſs the defendant ſo removing the ſame, ſhall give ſpecial bail for payment of the debt and coſts. But the great and efficacious writ, in all manner of illegal conſinement, is that of *habeas corpus ad ſubjiciendum*, directed to the perſon detaining another, and commanding him to produce the body of the priſoner, with the day and cauſe of his caption and detention, to do, ſubmit to, and receive the award of the judge or court. (St. Trials, viii. 142) This is a high prerogative writ, iſſuing by the common law out of the court of king's bench, not only in term time, but alſo during the vacation, by a *fiat* from the chief juſtice, or any other of the judges, and running into all parts of the king's dominions; for the king is at all times entitled to have an account, why the liberty of any of his ſubjects is reſtrained (Cro. Jac. 543.), wherever that reſtraint may be inflicted. If it iſſues in vacation, it is uſually returnable before the judge himſelf who awarded it; and he proceeds by himſelf thereon (4 Burr. 856.); unleſs the term ſhould intervene, and then it may be returned in court. (Ibid. 460. 542. 606.) Indeed, if the party were privileged in the courts of common pleas and exchequer, as being (or ſuppoſed to be) an officer or ſuitor of the court, an *habeas corpus ad ſubjiciendum* might alſo by common law have been awarded from thence (2 Inſt. 55. 4 Inſt. 290, 2 Hal. P. C. 144. 2 Ventr. 24.); and if the cauſe of impriſonment were palpably illegal, they might have diſcharged him (Vaugh. 155.); but if he were committed for any criminal matter, they could only have remanded him, or taken bail for his appearance in the court of king's bench (Carter, 221. 2 Jon. 13.); which occaſioned the common pleas for ſome time to diſcountenance ſuch applications. But ſince the mention of the king's bench and common pleas, as co-ordinate in this juriſdiction, by ſtatute 16 Car. I. c. 10, it hath been holden, that every ſubject of the kingdom is equally entitled to the benefit of the common law writ, in either of theſe courts, at his option. (2 Mod. 198. Wood's Caſe. C. B. Hil. 11 Geo. III.) It hath alſo been ſaid, and by very reſpectable authorities (4 Inſt. 182. 2 Hal. P. C. 147.), thas the like *habeas corpus* may iſſue out of the court of chancery in vacation; but as no precedent could be found upon the famous application to lord Nottingham by Jenks, his lordſhip refuſed it.

In the king's bench and common pleas it is neceſſary to apply for it by motion to the court (2 Mod. 306. 1 Lev. 1.), as in the caſe of all other prerogative writs (*certiorari*, prohibition, *mandamus*, &c.) which do not iſſue as of mere courſe, without ſhewing ſome probable cauſe, why the extraordinary power of the crown is called in to the party's aſſiſtance; and when a probable ground is ſhewn, that the party is impriſoned without juſt cauſe (2 Inſt. 615.), the writ of *habeas corpus* is then a writ of right, which "may not be denied, but ought to be granted to every man that is committed to priſon, or detained there, or otherwiſe reſtrained, though it be by the command of the king, the privy-council, or any other." Com. Journ. 1 April, 1628.

The writ of *habeas corpus* was originally ordained by the common law of the land, as a remedy for ſuch as were unjuſtly impriſoned, to procure their liberty; but many abuſes having been introduced into the mode of granting it, it became neceſſary to prevent them by modern ſtatutes. Accordingly, by the petition of right, 3 Car. I. it is enacted, that no freeman ſhall be impriſoned or detained, without cauſe ſhewn, to which he may make anſwer according to law. And by 16 Car. I. cap. 10. if any perſon be reſtrained of his liberty by order or decree of any illegal court, or by command of the king's majeſty in perſon, or by warrant of the council-board, or of any of the privy-council, he ſhall, upon demand of his counſel, have a writ of *habeas corpus*, to bring his body before the court of king's bench or common pleas; who ſhall determine whether the cauſe of his commitment be juſt, and thereupon do as to juſtice ſhall appertain. The methods of obtaining this are farther pointed out and enforced by 31 Car. II. cap. 2. See the next article.

HABEAS *Corpus Act* is the famous ſtatute 31 Car. II. cap. 2. which ſome have called the ſecond *Magna Charta*, and bulwark of Engliſh liberty. The ſubſtance of this important ſtatute is compriſed in the following particulars; *viz.* 1. That the writ of *habeas corpus* ſhall be returned, and the priſoners brought up within a limited time, according to the diſtance, not exceeding in any caſe twenty days. 2. That ſuch writs ſhall be endorſed as granted in purſuance of this act, and ſigned by the perſon awarding them. 3. That on complaint and requeſt in writing by or on behalf of any perſon committed and charged with any crime (unleſs committed for treaſon or felony, expreſſed in the warrant, or for ſuſpicion of the ſame, or as acceſſary thereto before the fact, or convicted or charged in execution by legal proceſs) the lord chancellor, or any of the twelve judges, in vacation, upon viewing a copy of the warrant, or affidavit that a copy is denied, ſhall (unleſs the party has neglected for two terms to apply to any court for his enlargement) award a *habeas corpus* for ſuch priſoner, returnable immediately before himſelf or any other of the judges; and upon the return made ſhall diſcharge the party, if bailable, upon giving ſecurity to appear and anſwer to the accuſation in the proper court of judicature. 4. That officers and keepers neglecting to make due returns, or not delivering to the priſoner or his agent, within ſix hours after demand, a copy of the warrant of commitment, or ſhifting the cuſtody of a priſoner from one to another, without ſufficient reaſon or authority (ſpecified in the act), ſhall for the firſt offence forfeit 100*l.* and for the ſecond offence 200*l.* to the party grieved, and be diſabled to hold his office. 5. That no perſon, once delivered by *habeas corpus*, ſhall be recommitted for the ſame offence, on penalty of 500*l.* 6. That every perſon committed for treaſon or felony ſhall, if he requires it, the firſt week of the next term, or the firſt day of the next ſeſſion of oyer and terminer, be indicted in that term or ſeſſion, or elſe admitted to bail; unleſs the king's witneſſes cannot be produced at that time; and if acquitted, or if not indicted and tried in the ſecond term or ſeſſion, he ſhall be diſcharged from his impriſonment for ſuch imputed offence; but that no perſon, after the aſſiſes ſhall be opened for the county in which he is detained, ſhall be removed by *habeas corpus*, till after the aſſiſes are ended; but

ſhall

ſhall be left to the juſtice of the judges of aſſiſe. 7. That any ſuch priſoner may move for and obtain his *habeas corpus*, as well out of the chancery or exchequer, as out of the king's bench or common pleas; and the lord chancellor or judges denying the ſame, on ſight of the warrant or oath that the ſame is refuſed, forfeit ſeverally to the party grieved the ſum of 500*l*. 8. That this writ of *habeas corpus* ſhall run into the counties-palatine, cinque-ports, and other privileged places, and the iſlands of Jerſey and Guernſey. 9. That no inhabitant of England (except perſons contracting, or convicts praying, to be tranſported, or having committed ſome capital offence in the place to which they are ſent) ſhall be ſent priſoner to Scotland, Ireland, Jerſey, Guernſey, or any places beyond the ſeas, within or without the king's dominions; on pain that the party committing, his adviſers, aiders, and aſſiſtants, ſhall forfeit to the party grieved a ſum not leſs than 500*l*. to be recovered with treble coſts; ſhall be diſabled to bear any office of truſt or profit; ſhall incur the penalties of *præmunire*, and ſhall be incapable of the king's pardon. And, leſt this act ſhould be evaded, by demanding unreaſonable bail, or ſureties, for the priſoner's appearance, it is declared by 1 W. & M. ſtat. 2 cap. 2. that exceſſive bail ought not to be required.

In conſequence of this act, it is now expected by the court, that, upon writs of *habeas corpus* at the common law, the writ ſhould be immediately obeyed, without waiting for any *alias* or *pluries*; otherwiſe an attachment will iſſue. Blackſt. Com. vol. i. p. 135, &c. vol. iii. p. 136, &c.

The preſervation of perſonal liberty by ſuch means, and in conformity to the explicit language of Magna Charta, "that no freeman ſhall be taken or impriſoned but by the lawful judgment of his equals, or by the law of the land," is of great importance to the public: for if once it were left in the power of any, the higheſt magiſtrate, to impriſon arbitrarily whenever he or his officers thought proper, there would ſoon be an end of all other rights and immunities. Some have thought, that unjuſt attacks, even upon life or property, at the arbitrary will of the magiſtrate, are leſs dangerous to the commonwealth than ſuch as are made upon the perſonal liberty of the ſubject. To bereave a man of life, or by violence to confiſcate his eſtate without accuſation or trial, would be ſo groſs and notorious an act of deſpotiſm, as muſt at once convey the alarm of tyranny throughout the whole kingdom: but confinement of the perſon, by ſecretly hurrying him to goal, where his ſufferings are unknown or forgotten, is a leſs public, a leſs ſtriking, and therefore a more dangerous engine of arbitrary government: and yet ſometimes, when the ſtate is in real danger, even this may be a neceſſary meaſure. But the happineſs of our conſtitution is, that it is not left to the executive power to determine when the danger of the ſtate is ſo great, as to render this meaſure expedient: for it is the parliament only, or legiſlative power, that, whenever it ſees proper, can authorize the crown, by ſuſpending the *habeas corpus* act for a ſhort and limited time, to impriſon ſuſpected perſons without giving any reaſon for ſo doing: as the ſenate of Rome was wont to have recourſe to a dictator, a magiſtrate of abſolute authority, when they judged the republic in any imminent danger. The decree of the ſenate, which uſually preceded the nomination of this magiſtrate, "dent operam conſules ne quid reſpublica detrimenti capiat," was called the "ſenatus-conſultum ultimæ neceſſitatis." In like manner this experiment ought only to be tried in caſes of extreme emergency; and in theſe the nation parts with its liberty for a while, in order to preſerve it for ever.

HABEEBA, in *Geography*, two iſlands in the Mediterranean, near the coaſt of Algiers; one of which, about three miles in circumference, lies ſeven miles N.E. from cape Figalo, with a harbour and freſh water. N. lat. 35° 46'. E. long. 0° 10'. The other, being ſmaller, is ſituated about 12 miles more to the E. four miles S.W. of cape Falcon.

HABELSCHWERDT, a town of Sileſia, in the county of Glatz, ſeated on the Nieſſe; dependent on the town of Glatz; but made a free town in 1319. The church belongs to the Roman Catholics; but the Lutherans are allowed to hold their religious aſſemblies in the town-houſe, eight miles S. of Glatz. N. lat. 50° 8'. E. long. 16° 24'.

HABENA, in *Surgery*, is the name of a bandage for keeping the ſides of wounds in contact.

HABENARIA, in *Botany*, from *habena*, a thong; on account of the long narrow ſtrips or ſegments of the lip, at leaſt in the original genus as founded by profeſſor Willdenow, though Mr. Brown has greatly augmented this genus on other principles. Willd. Sp. Pl. v. 4. 44. Brown. Prod. v. 1. 312. (Orchis; Linn. Gen. 461. Swartz. Orchid. 6.) —Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* three-leaved; leaflets elliptical, concave, obtuſe; the uppermoſt vaulted. *Cor.* Petals two, very narrow, longer than the calyx, ſpreading, ſometimes divided. Nectary a lip proceeding from the lower part of the ſtyle, in three deep, long, narrow ſegments, with a ſpur behind. *Stam.* Anther terminal, of two parallel vertical cells, with an elongated ſpur at the baſe of each; maſſes of pollen oblong, their ſtalks each inſerted into a naked gland. *Piſt.* Germen inferior, club-ſhaped, angular, erect, ſlightly twiſted; ſtyle very ſhort; ſtigma concave, in front, under the anther. *Peric.* Capſule inferior, oblong, taper, of one cell and three valves. *Seeds* numerous, minute, tunicate.

Eſſ. Ch. Calyx-leaves ſlightly ſpreading; the upper one vaulted. Petals long and linear. Nectary with a ſpur. Anther terminal, of two parallel vertical cells, with two horns at its baſe.

The only ſpecies in Willdenow are,

1. H. *macroceratitis*. (Orchis habenaria; Linn. Sp. Pl. 1331. Swartz. Obſ. 319. t. 9.)—"Spur awl-ſhaped, thrice as long as the germen. Leaves ovate."—Native of graſſy, flat places among the mountains of Jamaica. *Swartz*. *Bulb* ſolitary, downy. *Stem* a foot or two high, ſimple, leafy, ſmooth. *Leaves* ſeveral, elliptic-lanceolate, acute. *Spike* of ſix or eight large white flowers, whoſe long narrow ſharp ſegments of the lip and petals, and ſtill longer ſpur, have a very peculiar appearance.

2. H. *brachyceratitis*. (Orchus monorrhiza; Swartz. Prod. 118.)—"Spur compreſſed, the length of the germen. Leaves lanceolate."—Native of Jamaica and Hiſpaniola. *Stem* about 20 inches high, according to Browne's Jamaica, whoſe firſt ſpecies of *Satyrium* this is ſaid to be. We have ſeen no ſpecimen of it.—Swartz firſt hinted that this plant and the former might probably together conſtitute a diſtinct genus.

HABENDUM, in *Law*, a word of courſe in a conveyance. In every conveyance are two principal parts, the *premiſes*, and the *habendum*: the office of the firſt is to expreſs the name of the grantor, the grantee, and the thing granted. See DEED.

The *habendum* is to limit the eſtate, ſo that the general implication, which, by conſtruction of law, paſſed in the premiſes, is by the *habendum* controuled and qualified.

Thus, if a grant be to "A and the heirs of his body" in the premiſes, *habendum* "to him and his heirs for ever," or *vice verſâ*; here A has an eſtate-tail, and a fee-ſimple expectant thereon. (Co. Litt. 21. 2 Roll. Rep. 19. 23. Cro. Jac.

Jac. 476.) But if it had been in the premiſes "to him and his heirs," *habendum* "to him for life," the *habendum* would be utterly void (2 Rep. 23. 8 Rep. 56.); for an eſtate of inheritance is veſted in him before the *habendum* comes, and ſhall not afterwards be taken away, or diveſted by it.

HABENGTON, Henry, in *Biography*, was one of the firſt Engliſh muſicians who received academical honours in our univerſities. Wood, in his Faſti, has been able to produce no names of muſicians that have been enrolled among the graduates of the univerſity of Oxford before the 16th century, though we are told of ſeveral at Cambridge of an earlier period. But academical honours in the faculty of muſic may be traced up to the year 1463, when Henry Habengton was admitted to the degree of bachelor of muſic at Cambridge, and Thomas Saintwix, doctor in muſic, was made maſter of King's College in the ſame univerſity.

HABENTIA, in *Law*, ſignifies riches. In ſome ancient charters, *habentes homines* is taken for rich men; and we read, *nec rex ſuum paſtum requirat, vel* habentes homines, *quos nos dicimus* feaſting men.

HABERDASHER, in *Commerce*, a ſeller of hats and other ſmall wares

The maſter and wardens of the company of haberdaſhers in London, calling to their aſſiſtance one of the company of cappers, and another of the hat-makers and mayors, &c. of towns, may ſearch the wares of all hatters who work hats with foreign wool, and who have not been apprentices to the trade, or who dye them with any thing but copperas and galls, or woad and madder; in which caſes they are liable to penalties by ſtat. 8 Eliz. cap. 7. and 5 Geo. II. cap. 22.

For the etymology of this denomination, ſee Berdash.

Haberdashers' *Hoſpital*. See Hospital.

HABERE *facias poſſeſſionem*, in *Law*, is a writ that lies where one has recovered a term for years in an action of ejectment, in order to put him into poſſeſſion again. See Execution.

Habere *facias ſeiſinam*, a judicial writ, which lies where a man has recovered lands in the king's court; directed to the ſheriff, commanding him to give him the ſeiſin thereof. See Execution.

This writ ſometimes alſo iſſues out of the records of a fine, directed to the ſheriff of the county where the lands lie; commanding him to give to the cognizee, or to his heirs, ſeiſin of the land whereof the fine is levied.

There is alſo a writ called *habere facias ſeiſinam, ubi rex habuit annum, diem, & vaſtum*; which lies for the delivery of lands to the lord of the fee, after the king had taken his due of a perſon's lands who was convict of felony.

Habere *facias viſum*, is a writ that lies in divers caſes, as in dower, formedon, &c. where a view is to be taken of the land or tenement in queſtion.

HABERGION, or Haubergeon, *Habergetum*, a coat of mail; an ancient piece of defenſive armour, in form of a coat, deſcending from the neck to the middle; and formed of little iron rings, or maſhes, linked into each other.

The word is alſo written *haberge, hauberge, haubere, haubert, hauther, hautbert*, and *hauberk*. Spelman takes it to have been formed from the ancient French *hault, high*, and *berg, armour, covering*; as ſerving to defend the upper part of the body. Du Cange and Skinner chooſe to derive it from the Belgic *hals*, or Teutonic *haltz, neck*, and *bergen, to cover*; as if it were a peculiar defence for the neck. Others would have it formed of *al, alla*, q. d. *all*, and *bergen, to cover*; as importing it a cover for the whole body.

HABESAN, in *Geography*, a town of Perſia, in the province of Mecran; 40 miles N.W. of Keluch.

HABESH. See Abyssinia.

HABHAZZIS, in *Botany*, a name given by Leo Africanus, and ſome other of the writers of geography, to a plant growing in many parts of Africa, which they ſay produces its fruit under the earth in form of ſmall round globules, which are much eſteemed as food, and have the taſte of an almond. The fruit, as it is called, is no other than the disjunct tubera of the root, which are connected by fibres or ſtrings, and are in the propagation of the plant very uſeful to its ſpreading over a large ſpot of ground in a little time; all the fibres which ſhoot out horizontally from the root being terminated by theſe tubera, and each of theſe ſending out on the oppoſite ſide ſeveral other fibres, which at due diſtances produce other tubera. The Africans dig up the ground at random near to the place where they ſee any of theſe plants, and never fail of picking up a great number of them. The plant which produces them is the *tarfi*, and they are eaten in many other places beſides Africa. The Spaniards are very fond of them, and call them *avellanda*, from their likeneſs to hazel-nuts in ſhape.

HABICHSPEI, in *Geography*. See Brenner.

HABICHTSWALD, a hilly territory of Germany, in the Heſſian territories.

HABILIMENTS *of War*, in our *Ancient Statutes*, ſignify armour, harneſs, utenſils, or other proviſions for war; without which there is ſuppoſed no ability to maintain war.

HABIRHAOUTCHIN, in *Geography*, a town of Chineſe Tartary, in the country of the Monguls. N. lat. 44° 10'. E. long. 114° 24'.

HABIT, in *Philoſophy*, an aptitude, or diſpoſition, either of mind or body, acquired by the frequent repetition of the ſame act; or, a facility of doing a thing, acquired by having done it frequently. This definition is ſufficient for habits of art; but the habits, which may, with propriety, be called principles of action, muſt give more than a facility; they muſt give an inclination or impulſe to do the action: and it is certain that, in many inſtances, habits have this force. Habit differs from inſtinct, not in its nature, but in its origin; the latter being natural, the former acquired. Both operate without will or intention, without thought, and therefore, ſays Dr. Reid (Eſſays, p. 117.), may be called "mechanical principles." Theſe principles, united, have no ſmall ſhare in forming the characters and manners of moſt men. See Instinct.

Others define habit an affection of mind or body, perſiſting by long uſe and continuance. In which ſenſe ἕξις, a conſtant habit, is diſtinguiſhed from διαθεσις, a preſent diſpoſition, liable ſoon to alter.

Habits may be diſtinguiſhed into thoſe of the mind, and of the body. Thus, virtue is called a habit of the mind; ſtrength, a habit of the body.

All natural habits, whether of body or mind, are modes of the body or mind, in which either perſeveres, till effaced by ſome contrary mode. Ariſtotle enumerates five habits of the mind; *viz.* underſtanding, knowledge, wiſdom, prudence, and art: whereas later writers only admit of three intellectual habits; *viz.* ſcience, prudence, and art: agreeable to the three kinds of objects, about which the mind has occaſion to be facilitated; which are either theoretical, practical, or effective.

Habits, conſidered, in a more reſtricted ſenſe, as principles of action, are, according to Dr. Reid, a part of our conſtitution, ſo that what we have been accuſtomed to do, we acquire not only a facility, but a proneneſs to do on like occaſions,

occafions, ſo that it requires a particular will and effort to forbear it; but to do it, requires very often no will at all.

Habits, as well as inſtinct, are, as he conceives, parts of our original conſtitution; having an evident uſe and deſign, though we can aſſign no cauſe of them, but the will of him who made us; for no man can ſhew a reaſon why our doing a thing frequently, ſhould produce either facility or inclination to do it.

Virtues and vices are conſidered by philoſophers under the notion of good and bad habits.

The archbiſhop of Cambray defines habits, in general, to be certain impreſſions left in the mind, by means whereof we find a greater eaſe, readineſs, and inclination to do anything formerly done, by having the idea ready at hand to direct us how it was done before. Thus, *e. gr.* we form a habit of ſobriety by having always before us the inconveniencies of exceſs; the reflections whereof, being often repeated, render the exerciſe of that virtue continually more and more eaſy.

F. Malebranche gives a more mechanical theory of the habits. His principle is, that they conſiſt in a facility which the ſpirits have acquired, of paſſing eaſily from one part of the body to another. He argues thus: if the mind act on and move the body, it is, in all probability, by means of a ſtock of animal ſpirits lodged in the brain, ready to be ſent at the motion of the will, by means of the nerves which open or terminate in the brain, into the muſcles of the body.

Now, an influx of ſpirits into a muſcle occaſions a ſwelling, and, of courſe, a ſhortening of the muſcle; and, conſequently, a motion of the part to which that muſcle is faſtened.

Farther, the ſpirits do not always find all the roads open and free, which they are to paſs through; whence that difficulty we perceive of moving the fingers with that quickneſs neceſſary to play on a muſical inſtrument; or of moving the muſcles neceſſary to pronounce the words of a foreign language. But, by degrees, the ſpirits, by their continual flux, ſmoothen the way; ſo that at length they meet with no reſiſtance at all. In this facility the ſpirits find of paſſing, when directed into the members of the body, habits conſiſt.

On this hypotheſis, it is eaſy to account for an infinity of phenomena relating to the habits. Why, for inſtance, children acquire new habits with more eaſe than grown perſons? Why it is difficult to get rid of inveterate habits? Whence that incredible quickneſs in the pronunciation of words, even without thinking of them; as is particularly obſervable in thoſe long accuſtomed to formulas, &c.

On this ground the faculty of memory appears to have very much the nature of a habit; inſomuch that in one ſenſe it may paſs for a habit.

Cuſtom, ſays Mr. Locke, ſettles habits of thinking in the underſtanding, as well as of determining in the will, and of motions in the body; all which ſeem to be but trains of motion in the animal ſpirits, which, once ſet a-going, continue in the ſame ſteps they have been uſed to, which, by often treading, are worn into a ſmooth path, and the motion in it becomes eaſy, and as it were natural. Eſſay on the Human Underſtanding, book ii. ch. 33. See ASSOCIATION *of Ideas*.

HABIT, in *Medicine*, is what we otherwiſe call the temperament, or conſtitution of the body; whether obtained by birth, or occaſioned by the manner of living.

An ill, diſtempered habit, without any particular apparent diſeaſe, the phyſicians uſually call a *cachexia*, or *cacochymia*.

A thing is ſaid to *enter the habit*, when it becomes intimately diffuſed throughout the body, and is conveyed to the remoteſt ſtages of circulation.

HABIT is alſo uſed for a dreſs, or garb; or the compoſition of garments wherewith a perſon is covered.

In this ſenſe we ſay, the habit of an eccleſiaſtic; of a religious, &c. the military habit, &c.

The principal part of the dreſs worn by the Jews and the Greeks was the ἱμάτιον and the χιτὼν: the former was an upper garment, conſiſting of a looſe piece of cloth wrapped round the body: the latter was an under garment, or tunic, which was faſtened cloſely round the body, and which fell down to the middle of the thigh. It has been, not unappropriately, obſerved that a perſon diveſted of the upper garment was, in the eaſtern language, ſaid to be *naked*, and thus David danced naked before the ark.

The ſeveral ſort of garments in uſe with both ſexes, among the Romans, were the toga, tunica, peluna, lacerna, chlamys, paludamentum, læna, ſtola, pallium or pella; which ſee reſpectively.

In the Eaſt it was the cuſtom, in times of deep mourning, to put off their upper garment; and this circumſtance accounts for the ſeptuagint tranſlation of Exodus, xxxiii. 4—6, in which Moſes gives an account of the mourning of the Iſraelites. It was likewiſe reckoned in the Eaſt a mark of reſpect often to change their garments; and to this frequent change of veſtments the Pſalmiſt alludes when he deſcribes the change which the heavens ſhall undergo as more ſpeedy, in compariſon with the eternity and immutability of God, than the laying aſide of a veſtment which kings and princes change often in a day. The changing of clothes was a token of Eaſtern magnificence; how wonderfully ſublime then, in this view, is the ſcriptural repreſentation of the majeſty of God "*thou* ſhalt change theſe heavens as a prince changes his veſture."

The different habits and clothes which the generality of the world wear, are, through inadvertency and inattention, very frequently the cauſe of very unhappy maladies. Mr. Winſlow, in the Memoirs of the Royal Academy of Sciences at Paris, has obſerved, that the greateſt attention and care are neceſſary on ſeveral occaſions in regard to this, as it is ſuppoſed, trifling article; and has given many inſtances of the ill effects of it. The ancients have obſerved the inconveniencies of many parts of dreſs, and daily obſervation confirms to us the many miſchiefs the ladies ſuffer from the ſtiff whale-bone ſtays they wear, and the diſorders of the viſcera of the lower belly, to which thoſe are ſubject who lace themſelves too tightly; and this is not only of dangerous conſequence to themſelves, but frequently is the death of children in breeding women.

The tight binding of the neck by the men's neckcloths, ſtocks, or the too tight collars of their ſhirts, &c. has been very frequently the only occaſion of ſeveral very terrible diſorders of the head, the eyes, and the breaſt; deafneſs, vertigoes, fainting, and bleedings at the noſe, are the frequent conſequences of this practice; and the phyſicians, conſulted for relief in theſe caſes, have found all means ineffectual, merely from their not attending to the cauſe of the malady; when a cure might have been, and often has been, made without the help of medicines, only by leaving off thoſe unnatural bandages which had been the occaſion of them, from the not ſuffering the free return of the blood by the jugular veins, which had paſſed up into the head, without moleſtation, by the carotid arteries.

Mr. Winflow has obferved, that the different motions of the bones of the foot, which are very free in their natural ftate, as it is very plainly feen in young children, are ufually wholly loft to us as we grow up, by means of the improper preffure of our fhoes. See the particular illuftration of thefe circumftances in Mem. Acad. Scienc. Paris, 1740.

HABIT is particularly ufed for the uniform garments of the religious, conformable to the rule and order whereof they make profeffion; as the habit of St. Benedict, of St. Auguftine, &c.

In this fenfe we fay abfolutely, fuch a perfon has taken the habit; meaning, he has entered upon a noviciate in a certain order. So he is faid to quit the habit, when he renounces the order. See Vow.

The habits of the feveral religious are not fuppofed to have been calculated for fingularity or novelty; the founders of the orders, who were at firft chiefly inhabitants of deferts and folitudes, gave their monks the habit ufual among the country people. Accordingly, the primitive habits of St. Anthony, St. Hilarion, St. Benedict, &c. are defcribed by the ancient writers as confifting chiefly of fheepfkins, the common dreffs of the peafants, fhepherds, and mountaineers of that time; and the fame they gave to their difciples.

The orders eftabliffhed in and about cities and inhabited places, took the habit worn by other eccleffiaftics at the time of their inftitution. Thus, St. Dominic gave his difciples the habit of regular canons, which he himfelf had always worn to that time. And the like may be faid of the Jefuits, Barnabites, Theatins, Oratorians, &c. who took the common habit of the eccleffiaftics at the time of their foundation. And what makes them differ fo much from each other, as well as from the eccleffiaftical habit of the prefent times, is, that they have always kept invariably to the fame form: whereas the eceleffiaftics and laics have been changing their mode on every occafion.

The eccleffiaftical habit only commenced about the time of Gregory the Great, *i. e.* it only began at that time to be diftinguifhed from the lay habit; *viz.* in the fixth century. The eftablifhment of the barbarous nations was the occafion thereof; for the laymen took the habit of the nations they had fubmitted to, but the prieffs kept to the Roman dreff.

The abbot Boileau has an expreff treatife on the eccleffiaftical habit; wherein he maintains, contrary to the common opinion and cuftom, that the eccleffiaftical habit fhould be a fhort one, and that a fhort habit is more decent than a long one. For the peculiar habit of the prieffs among the Jews, Greeks, and Romans, fee PRIESTS.

HABIT-ANI, in *Ornithology*. See SYLVIA *Campeftris*.

HABITATION, a dwelling-place, or *houfe*; which fee.

HABITATION is fometimes alfo ufed for *cohabitation*.

HABITE *and* REPUTE, in *Scots Law*, the common opinion of the people, among whom a perfon lives, with refpect to any circumftance relating to him.

HABITUAL, fomething that is become a habit or habitude. Thus we fay an habitual, or inveterate difeafe; habitual fin, &c.

HABITUAL *Grace*. See GRACE.

The Romifh divines hold *habitual* grace only neceffary in order to be faved; and *actual* grace to the doing any thing meritorious.

HABITUDE, HABITUDO, in the *Schools*, fignifies the refpect or relation which one thing bears to another.

In this fenfe, habitude is one of Ariftotle's categories. See RELATION.

HABITUDE is alfo ufed, in *Philofophy*, for what we popularly call habit; *viz.* a certain difpofition, or aptitude, for the performing or fuffering of certain things; contracted by reiterated acts of the fame kind. See HABIT.

HABOST, in *Geography*, a town of Perfia, in the province of Segeftan; 160 miles S.E. of Zareng.

HABRAH, a conffiderable river of Africa, in the weftern province of Algiers, which falls into the Sigg; fo called from a numerous tribe of Arabs who live upon its banks. The mouth of thefe confluent ftreams is called El Muckdah, or the Ford, which, except in the rainy feafon, leaves the fand dry. This was probably the *Cartennus* of Ptolemy.

HABSBURG, or HAPSBURG, a bailiwick of Switzerland, in the canton of Lucerne.—Alfo, a caftle, fituated in the canton of Berne, on the right bank of the Aar, about three miles above the town of Bruck; 5 miles N. of Lenzburg.

HABSHEIM, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the diftrict of Altkirch; 9 miles N.N.E. of Altkirch. The place contains 1416, and the canton 12,681 inhabitants, on a territory of 222½ kiliometres, in 17 communes.

HABU, a village of Egypt, in which are the ruins of a magnificent temple, and near which is the celebrated ftatue of Memnon, and another coloffal ftatue; feated on the left bank of the Nile, and 25 miles N. of Syene.

HABUR, a fmall ifland in the Red fea, 6 miles from the coaft of Arabia. N. lat. 16° 45'.—Alfo, a town of Arabia, in the province of Yemen; 12 miles S.W. of Chamir.

HACARI, a town of Peru, in the diocefe of Lima; 45 miles S.E. of Nafca.

HACBOTE, in our *Old Writers* a recompence or amends for violence offered to perfons in holy orders.

HACHA, RIO DE LA, in *Geography*, a government or diftrict, comprehended within the royal audience of Santa Fé, the capital of New Granada, bounding the government of Maracaibo on the weft. This diftrict is furrounded on two fides, *viz.* N. and N.W. by the ocean, and on the third, E. by the gulf of Venezuela. The town of the fame name is fituated at the mouth of the river bearing alfo the fame appellation, which is navigable for light veffels, and the harbour of which is expofed to the N. wind. The environs are very fertile; they have mines of gold and precious ftones; and on the coaft is a pearl-fifhery. The interior of the country is infefted with tigers, and the river with alligators. The town lies 210 miles E.N.E. from Carthagena. N. lat. 11° 28'. W. long. 72° 46'.

HA-CHAM-POU, a town of Afia, in the kingdom of Corea. N. lat. 42° 40'. E. long. 132 35.'

HACHENBURG, a town of Germany, in the county of Sayn; 17 miles N.E. of Coblentz. N. lat. 50° 35'. E. long. 7° 54'.

HACHES, and HACHING. See HATCHING.

HACHOWKA, in *Geography*, a town of Poland, in Volhynia; 34 miles N. of Zytomiers.

HACK, in *Rural Economy*, a fort of pick-axe or mattock, which has only one end, and that a broad one. It is a kind of half mattock, which is found to be a very ufeful tool for many different purpofes.

HACK, a term pretty generally applied to a road-horfe, whether let out to hire or the contrary. It is fometimes applied as a mark of inferiority to fuch forts of horfes.

HACKANBO, in *Geography*, a town of Sweden, in the province of Upland; 28 miles N. of Upſal.

HACKAS, a town of Sweden, in the province of Jamtland; 18 miles S. of Oſterſund.

HACKERT, John, in *Biography*, a landſcape-painter, who was born at Amſterdam about the year 1635. His peculiar taſte induced him to paint romantic ſcenery, and therefore, that he might draw with juſt character, he travelled through the mountainous countries of Germany and Switzerland; making ſketches of thoſe things which moſt excited his admiration, and would beſt ſerve him in his future application of the talents nature had endowed him with for the profeſſion of art. He obtained very conſiderable rank as a painter: his manner of handling was delicate and pleaſing. Not being very ſkilful in deſigning figures, he judiciouſly ſought aid in that particular from Adrian Vandevelde, and by this means highly increaſed the value of his pictures.

HACKET, John, an Engliſh prelate, was born at London in the year 1592, and educated at Weſtminſter ſchool, till he was elected to Trinity college, Cambridge, in the year 1608. Having at this laſt place taken his degrees, he undertook the office of tutor with great reputation, and pupils from ſome of the beſt families in England were committed to his care. In one of the long vacations he compoſed a Latin comedy, entitled "Loyala," which was twice acted before king James I. and printed. In 1618 he was admitted to holy orders, and patronized by Dr. Williams, biſhop of Lincoln, by whom he was elected his chaplain, and introduced to other conſiderable preferment. In 1625 Mr. Hacket was nominated by the king to attend his ambaſſador to Germany, but fearing the reſentment of the Jeſuits, whom he had attacked very ſeverely in his "Loyala," he declined the office. In 1628 he took his degree of D.D. and in 1631 was made arch-deacon of Bedford. Soon after the breaking out of the civil wars he was appointed one of a ſubcommittee, ſelected to prepare matters for diſcuſſion of the "committee of accommodation," appointed by the houſe of lords to examine into the innovations in doctrine and diſcipline introduced into the church ſince the Reformation, and to conſider of ſuch amendment in the liturgy as might obviate the principal objections of the Puritan party, and prevent the ruin of the eccleſiaſtical conſtitution. This committee, however, was broken up, partly in conſequence of the jealouſy and oppoſition of the biſhops, and partly owing to the ferment occaſioned by the diſcovery of the king's deſign of bringing the army to London, to diſſolve parliament. After this Dr. Hacket was preſented to a prebend and reſidentiaryſhip in the cathedral church of St. Paul's, but the confuſion into which the country fell prevented him from enjoying much of the emoluments connected with theſe offices. He was zealouſly attached to the eccleſiaſtical form of church government, and at his houſe there were private meetings held by the biſhops and clergy, whence letters were circulated among the divines in different parts of England, to exhort them to ſtedfaſtneſs in the cauſe of epiſcopacy and monarchy. His zeal led him into difficulties, and he was impriſoned by the parliamentary power. He was, however, in a very ſhort time, liberated, and upon the reſtoration of Charles II. recovered all his preferments, and was offered the biſhopric of Glouceſter, which he refuſed, though he afterwards accepted that of Litchfield and Coventry, and was conſecrated in the year 1661. When he took poſſeſſion of the ſee, he found the cathedral church at Litchfield in ruins, and his epiſcopal palaces in a ſtate of dilapidation, owing to the rage of the republicans, which had been levelled againſt them; at an expence of 20,000*l.* he reſtored thoſe buildings, and rendered them more complete and beautiful than they were before their deſtruction. He died at Litchfield, in 1670, having attained to his ſeventy-ninth year. He was a prelate of great and extenſive learning, diſtinguiſhed for piety, integrity, benevolence, and charity, and for ſtrictly virtuous and exemplary manners. During his life he publiſhed a ſingle ſermon, and his "Loyala," but after his death "A Century of his Sermons, upon ſeveral remarkable ſubjects," was printed by Dr. Plume, and in 1693 appeared his learned and valuable "Life of his Patron Archbiſhop Williams." Biog. Brit.

HACKETSTOWN, in *Geography*, a poſt-town of the county of Carlow, and province of Leinſter, Ireland, 41½ miles S. W. of Dublin.—Alſo, a ſmall poſt-town of America, in Suſſex county, New Jerſey, on the N. W. ſide of Muſconecunk river; 120 miles N. N. E. of Philadelphia.

HACKINSAC, the chief and poſt-town of Bergen county, New Jerſey, ſituated near the W. bank of a river of the ſame name, which unites with Paſſau river at the head of Newark bay, and is navigable about 15 miles. The town, which is 20 miles N. W. from New York, is chiefly inhabited by Dutch, and the houſes, moſtly of ſtone, are conſtructed in the Dutch taſte. It has a Dutch and epiſcopal church, a court-houſe, and a flouriſhing academy. The people, who are generally farmers, carry their productions to New York. N. lat. 40° 53′. W. long. 74° 4′.

HACKLE, in *Rural Economy*, a term ſometimes applied to a ſmall ſort of hack. It is alſo applied to the practice of raiſing turnips, by means of a ſmall two-pronged hack.

Hackle, the name of a tool employed in the buſineſs of dreſſing flax. See Flax.

Hackles, in *Agriculture*, a term provincially uſed in many places to ſignify the handfuls, cones, or ſinglets of bean-crops that are tied and ſet up after being pulled, in order to prevent their being injured by the wet.

HACKLUYT'S Head-Land, in *Geography*, the weſtern point of the iſland of Amſterdam, in the North ſea, near the N. W. coaſt of Spitzbergen. N. lat. 79° 47′. E. long. 9° 11′.

HACKNESS, a cape on the S. E. coaſt of the iſland of Shapinſha. N. lat. 58° 53′. W. long. 2° 42′

HACKNEY, a large and populous pariſh in the hundred of Oſſulſton and county of Middleſex, conſiſted, in the year 1801, of 2134 houſes, which contained 12,730 inhabitants. The ſouthern boundary of this pariſh joins to that of Shoreditch, London, and is connected with the metropolis by ſeveral new rows and ſtreets that have been erected within a few years. Hackney pariſh comprehends the following hamlets: Upper and Lower Clapton, Dalſton, Shacklewell, Kingſland, and Homerton. All theſe places are chiefly occupied by, and belong to, various merchants and tradeſmen of London, who reſide here with their families, and tranſact buſineſs at their reſpective counting-houſes, warehouſes, and ſhops in the metropolis. This extenſive pariſh contains one pariſh church and ſeveral chapels; ſome of which belong to it, and others are appropriated to different claſſes of diſſenters. A new church, on a large ſcale, was begun here in 1791; the old church being inſufficient to hold the congregation. It ſtands on high ground at ſome diſtance from the old fabric; of which the tower and part of the chancel remain. The preſent church is built of brick from deſigns by Mr. Blackburn and Mr. Spiller, and, for commodious and appropriate arrangement, is much to be admired. A chapel-of-eaſe, in Wells-ſtreet, has been recently erected from deſigns by Mr. James Savage; the ground for which was given by the Rev. Mr. Norris. Another chapel for the Unitarians, called the "Gravel-Pit-Meeting-Houſe," is alſo a modern ſtructure, and is built

from deſigns by Mr. Edmund Aikin, to whoſe ſcience and taſte it is an honourable memorial. In the old church and its cemetery, ſeveral diſtinguiſhed perſonages have been interred; among whom the following names occur: Chriſtopher Urſwick, an eminent ſtateſman under Henry VII. and rector of this pariſh; Henry, earl of Northumberland, who died at his manor-houſe in the time of Henry VIII.

Hackney, it is ſaid, was the firſt place in the vicinity of London where ſtage-coaches applied for hire; and hence the origin of the name hackney-coaches. The lords Brooke formerly had a country manſion here, which is now a receptacle for lunatics, and ſtill called Brooke-houſe. Another ancient building in Wells-ſtreet, called St. John's-palace, is ſuppoſed to have been the reſidence of the knights of St. John of Jeruſalem. On Hackney-marſh have been found the remains of a ſtone-cauſeway, which is conjectured to have been the courſe of a Roman road from London into Eſſex. See Lyſons's "Environs of London," vol. ii., and Brayley's "London and Middleſex," vol. ii. 8vo. 1811.

Hackney, in *Rural Economy*, the name of a ſaddle-horſe, or one that is chiefly uſed for the purpoſe of riding. See Horse.

Hackney. See Haqueny.

Hackney *Coach*. See Coach.

HACKSPAN, Theodore, in *Biography*, was born at Weimar, in Thuringia, in the year 1607. He ſpent ſeven years at Jena in the ſtudy of theology and the Oriental languages. He acquired at this and other places ſuch a reputation in this kind of learning, that he was the firſt perſon fixed on to teach the Eaſtern tongues at Altdorf. Here, alſo, he undertook the profeſſorſhip of theology in connection with his other office. By intenſe application to his ſtudies, and to the performance of thoſe duties attached to his ſituation, he brought on a decline, to which he fell a ſacrifice in the year 1649, when he was in the 52d year of his age. He was author of many learned works, which did honour not only to the talents of the writer, but to the age and country in which he flouriſhed. He was regarded as being more perfectly acquainted with the Hebrew, both ſcriptural and rabbinical, the Syriac, the Chaldee, and the Arabic languages, than any of his contemporaries. Moreri.

HACMAN, in *Geography*, a town of the iſland of Ceylon; 24 miles N. of Matura.

HACUB, in *Botany*, Rauwolf. It. t. 74. See Guxdelia.

HACZEG, in *Geography*, a town of Tranſilvania; 30 miles S. of Hunyad.

HAD, El, a town of Africa, in the weſtern province of Algiers, at the conflux of the Mina and Shelliff; 50 miles E. N. E. of Oran.

HADAJA, a town of Africa, in Fez, long deſolate, but lately peopled by a colony of Arabs; 120 miles N. E. of Fez. N. lat. 34° 10'. W. long. 3°.

HADAMAR, a town of Germany, in the principality of Naſſau, and capital of a ſmall principality, called "Naſſau-Hadamar," having a ſuperb chateau, and a convent of Franciſcans; 15 miles S. W. of Dillenburg. N. lat. 50 24'. E. long. 8 1'.

HADARISA, a town of Arabia; 40 miles S. of Cathem.

HADAWI, a town of Abyſſinia; 30 miles S. of Arkeeko.

HADDAM, a poſt-town of America, in Middleſex county, Connecticut, on the W. ſide of Connecticut river, ten miles S. E. of Middletown, containing 2307 inhabitants. Oppoſite to this, on the E. ſide of the river, is Eaſt Haddam, a poſt-town, ſettled in 1704, and containing 2805 inhabitants.

HAD-DESSA, a mountain of Africa, in the country of Tunis, at the eaſtern extremity of the lake of Marks, the "lacus Tritonis" of the ancients, compoſed entirely of ſalt, hard and ſolid like a ſtone, and of a blue or violet colour, which being diſſolved by the dew, becomes white as ſnow.

HADDINGTON. See Hadington.

HADDO, a town of Scotland, in the county of Aberdeen; nine miles N. N. E. of Inverary.

HADDOCK, in *Ichthyology*. See Gadus *Æglefinus*.

HADDON, Walter, in *Biography*, was deſcended from a reſpectable family in Buckinghamſhire, and born in the year 1516. He was educated partly at Eton, and partly at King's college, Cambridge, of which he became a fellow. He was a very elegant ſcholar, wrote Latin with great purity and claſſical taſte, and made himſelf a proficient in poetry and oratory. He devoted himſelf to the purſuit of the civil law, in which he took a doctor's degree, and read public lectures. He was likewiſe appointed profeſſor of rhetoric, and orator of the univerſity, and in the reign of Edward VI. he was elected maſter of Trinity-hall, in the room of Gardiner. In 1550 he ſerved the office of vice-chancellor, and then was elected preſident of Magdalen college, Oxford. Upon the acceſſion of Mary he was glad to ſeek retirement, in which he quietly remained, till death put an end to her bloody reign. By queen Elizabeth he was appointed one of her maſters of requeſts, and by the archbiſhop of Canterbury he was made judge of the prerogative court. He was employed in various official ſituations, and would have attained to high preferment, but his death prevented the good intentions of his patrons. He died in 1571-2, leaving behind him many works which teſtify to his learning and talents. He had a principal concern in drawing up and putting into Latin the code of eccleſiaſtical law, entitled "Reformatio Legum Eccleſiaſticarum," edited in 1571 by John Foxe. He publiſhed, in 1563, a reply to Ozorio's letters, entitled "Admonitio ad Elizabetham, Reginam Angliæ." Some original letters of Dr. Haddon are preſerved among the Harleian MSS. Biog. Brit.

HADDONFIELD, in *Geography*, a ſmall poſt-town of America, in Glouceſter county, New Jerſey; nine miles S. E. by E. from Philadelphia.

HADE, in *Mining*, ſignifies the inclination, or deviation from the vertical of a mineral vein; in different mining diſtricts this is called the pick, want, tilt, fall, &c. and ſuch veins are ſaid to under-beat, batter-off, decline, &c. In a great majority of caſes of hading veins, the ſame is occaſioned by the dip or inclination of the rock or ſtratum in which the vein is found, and owing to the poſition of the veins being moſtly perpendicular to the planes of the ſtrata, but this is not always the caſe, ſince ſome veins hade in different directions even in the ſame rock, as firſt N. then S. and then N again, &c. The following are the mines in Derbyſhire which hade in a remarkable degree or manner, *viz.* Bondog-hole, Bacchus, Barrow, Bright-ſide, Corderlow, Earl of Mar, Gang, Hading-vein, Little-paſture, Longſdon-edge venture, Odin, Mandale, Rantor, Thaws-wood, Thiſtley, Water-hole, Yield, Yokecliff, &c. as enumerated in Mr. Farey's Report on Derbyſhire, where much information on this and other phenomena of the veins of this diſtrict will be found; ſee alſo Mr. Werner's "New Theory of Veins," tranſlated by Dr. C. Anderſon, Williams's "Mineral Kingdom," 2d edit.; and W. Forſter's "Treatiſe on a Section of Strata," Newcaſtle, 1809.

HADELAND, in *Geography*, a town of Norway, in the dioceſe of Aggerhuus; 32 miles N. N. E. of Chriſtiania.

HADELN, a ſmall county of Germany, near the Elbe, bordering on the duchy of Bremen, about 8 miles long, and of the ſame breadth, ſecured by a large dyke from inundations. The ſoil is fertile, and the country abounds in grain, fruit, cattle, and fiſh. It formerly belonged to the elector of Hanover.

HADEQUIS, a town of Morocco; 20 miles E. of Mogador.

HADERSLEBEN, a ſea-port of Denmark, in the duchy of Sleſwick, on the N. ſide of a gulf, about 8 miles from its mouth, which opens into the Little Belt. Its harbour can accommodate only ſmall veſſels; and it principally depends for its ſupport on being the paſſage from Sleſwick to the iſland of Fyen; 24 miles N. of Ripen. N. lat. 55° 15′. E. long. 9° 30′.

HADES. See Ades.

HADESOGN, a town of Norway, in the dioceſe of Bergen; 36 miles S. E. of Bergen.

HADGI-Bestash, a town of Aſiatic Turkey, in Caramania; 28 miles S. E. of Kir-ſhehr.

Hadgi-*Hamzeh*, a town of Aſiatic Turkey, in the government of Sivas; 31 miles E. of Kiangari.

Hadgi-*Keui*, a town of Aſiatic Turkey, in the government of Sivas; 30 miles N. W. of Amaſieh.

Hadgi-*Morat*, a town of Aſiatic Turkey, in the government of Sivas; 36 miles N. N. E. of Sivas.

HADJAR el Hamar, a town of Africa, in Algiers; 29 miles S. W. Conſtantina.

HADIE′, a town of Arabia, in Yemen; 16 miles E. of Beit-el-Fakieh.

HADINGTON, a royal borough, and county town of Eaſt-Lothian, or Hadingtonſhire, Scotland, is ſeated on the banks of the river Tyne, at the diſtance of about 17 miles eaſt of Edinburgh. It conſiſts of four ſtreets, which croſs each other nearly at right angles; and contained, in the year 1791, a population of about 3915 inhabitants. The return to parliament in 1801 was, 711 houſes, and 4049 inhabitants. Connected with the town by a bridge of three arches acroſs the Tyne, is a ſuburb called Nungate, which, with another called Giffordgate, contained 502 inhabitants. Nungate derives its name from a nunnery, which was founded here in 1178 by Ada, the mother of king Malcolm IV. who alſo granted a charter to the town, wherein ſhe ſtyles it "meum burgum de Haddington." The town is governed by a provoſt, three bailiffs, a dean of guild, treaſurer, and 12 counſellors; and, in conjunction with the other towns of the county, returns one member to parliament. Formerly this place was fortified, and ſome fragments of its embattled walls remain. Hadington has ſuſtained material injury both by fire and water: in the year 1775 the water of the Tyne roſe full 17 feet above its uſual level, and inundated nearly one-half of the town. Of the public buildings, the church is the principal. It is a large ancient edifice, apparently built about the thirteenth century; and was originally attached to a monaſtery of Franciſcans. Only part of it is uſed for parochial purpoſes: the other part is in ruins. It contains the family vault of the Maitlands, who poſſeſſed, for many ages, the eſtates of Leithington, now belonging to lord Blantyre. Among the monuments in the church is one to the memory of John Maitland, baron of Thirlſtane, lord high chancellor of Scotland. His epitaph was written by king James VI. Here are ſome marble effigies of the dukes of Lauderdale. A town-houſe was built here in 1748 by the late Mr. Adams, architect. Hadington has two yearly fairs, and a weekly market, which is abundantly ſupplied with corn.

In the vicinity of the town are ſeveral handſome and reſpectable manſions; the moſt noted of which is Amisfield, the ſeat of the earl of Wemyſs; who poſſeſſes ſome fine pictures. Other ſeats are named Leithington, Stevenſtone, Adderſtone, Clerhington, and Letham. At Hadington was born John Knox, the diſtinguiſhed reformer of Scotland, who died in 1572. After his death was publiſhed his "Hiſtory of the Reformation of Religion within the Realm of Scotland."

Sinclair's Statiſtical Account of Scotland, vol. vi. p. 535, written by the Rev. George Barclay, who furniſhed, according to ſir John Sinclair, "a very complete, intelligent, and ſatisfactory hiſtory of Hadington pariſh," for the firſt volume of the Tranſactions of the Society of Antiquaries of Scotland. An account of the town will alſo be found in the ſecond volume of Chalmers's Caledonia, p. 412, &c.

HADINGTONSHIRE, or East-Lothian, a county of Scotland, is ſituated at the ſouth-eaſtern extremity of that part of the kingdom; and is bounded by the German ocean on the eaſt, the Frith-of-Forth on the north, the county of Edinburgh on the W. and S. W.; and Berwickſhire on the S. and S. E. The area thus circumſcribed meaſures, on an average, about 24 miles from W. to E. and nearly 16 in a tranſverſe line. According to Armſtrong's map, it is calculated "to contain 297 ſquare miles, or 190,363 Engliſh acres, of which about 64 parts are arable, 16 meadows, or low-lying land, and 20 parts, or one-fifth of the whole, conſiſts of hills and waſtes, a great part of which is uncultivated." This is the account of Mr. Somerville, who, in another part of his "Agricultural Survey of Eaſt-Lothian," ſays, that in point of ſoil, cultivation, and produce, this county "holds the firſt rank in Scotland; and in ſome of theſe reſpects, particularly the mode of huſbandry, it will bear a compariſon with the beſt improved diſtricts in England; notwithſtanding the great difference of latitude, being ſituated between 55° 46′ 10″, and 56° 3′ 10″ of north latitude, three degrees farther north than the county of Norfolk, whoſe rival it is in many reſpects." The area of this county ſeems to have been called Bernicia, from the abdication of the Romans till the epoch of 1020. The Saxon ſettlers afterwards denominated the whole country lying along the ſea and the forth, from the Tweed to the Avon, Lothian. This diſtrict was known diſtinct from Scotland during the reign of David I. Afterwards it was divided into three parts, and called, from their relative ſituation to each other, Eaſt-Lothian, Mid-Lothian, or Edinburghſhire, and Weſt-Lothian, or Linlithgowſhire.

In an agricultural point of view this county may be divided into four diſtricts, in particulariſing which, the general character of the whole will be pointed out. 1. Coaſt-land; 2. Midlands; 3. Uplands; and, 4. Mountainous, or Lammer-muir diſtrict. The firſt is a ſhelving or ſloping tract of land, affording a fine fertile ſoil; the ſecond is a ridge of ground north of the Tyne, ſloping partly to that river and partly to the coaſt-land. It comprehends a great proportion of the arable land of the county, including every variety of ſoil, a great part of which is extremely valuable. The third conſiſts of a tract of varied breadth, elevated above the mid-lands, and continuing along the baſe of the mountains, nearly the whole extent of the county. The fourth conſiſts of an extenſive range of mountains, which commences at the ſouth-weſt extremity of the county, and terminates at a high promontory called St. Abb's-head, on the eaſt ſhore. The greater part of this is moor, or moſs; but ſome parts in the glens, or low-lands, between the hills, are kept under a regular rotation of crops. Farming is the chief purſuit of the inhabitants, but on the ſea-coaſt many are employed in fiſhing, ſalt-

ſalt-making, and in commercial purſuits. At ſome places the linen and woollen manufactures have been eſtabliſhed, and at Preſton-pans is a large manufactory for oil of vitriol, and another for ſal-ammoniac. The weſtern part of the county abounds with coal; beſides which lime-ſtone, and red granite or iron-ſtone conſtitute the chief mineral ſubſtances beneath the ſurface. Several ſtreams and rivulets are found in the county; but it has only one river of any conſequence, which extends through the whole in a north-eaſterly direction, entering it near Ormiſton, and leaving it at Tyningham, where it forms a bay.

Hadingtonſhire abounds with gentlemens' ſeats, ſome of which are built on a large and commodious ſcale: and ſome of their proprietors reſide, almoſt wholly, at them. Amiſfield and Gosford belong to the earl of Wemyſs; Broxmouth to the duke of Roxburgh; Yeſter-caſtle, the ſeat of the marquis of Tweedale; Tyningham belongs to the earl of Hadington; Leithington, the ſeat of lord Blantyre; Balincrief, the ſeat of lord Elibank; Ormiſtown-hall, a ſeat of the earl of Hopetown; Dunglaſs, the ſeat of ſir James Hall, bart.; Lockend, ſir Peter Warrender; Gilmerton, ſir George Kinloch. Beſides theſe the county contains ſome ſeats called caſtles, which belong to ancient families: the principal are the caſtles of Dunbar and Hailes, once the property of the earl of Bothwell. Tantallan, the reſidence of the Douglaſſes: the caſtle of Redhouſe, the property of the Hamiltons: Dirlton caſtle, belonging to the Neſbit family: and Luffneſs, to the Hopes.

Near the northern coaſt of this county are the ſmall iſlands of Baſs, Fiddrie; alſo ſome rocks called Craig-Leith, Ibres, and Lamb. The firſt is a ſingular inſulated rock of about one mile in circumference, and is chiefly inhabited by rabbits and ſea-birds.

Hadingtonſhire contains the three royal boroughs of Hadington, North-Berwick, and Dunbar. According to the parliamentary report of 1801, it then contained 6257 houſes, and 29,986 inhabitants. Groſe, in "The Antiquities of Scotland," gives accounts, with prints, of the following ancient buildings in this county. A ruin on the ſhore at North-Berwick; a Ciſtertian nunnery at the ſame place; Dirleton-caſtle; Dunbar-caſtle; Gulene church; Hadington church; Hales-caſtle; Innerwick-caſtle; and Tantallan, or Tamtallon-caſtle. Antiquarian objects of a more remote character are, an encampment, called Cheſters in Bolton pariſh; another of a circular form at Gawald; a third at Carfrac; a fourth on Prieſtlaw, which is encompaſſed by four ditches, and meaſures 2000 feet in circumference. The county is divided into three preſbyteries, and theſe again divided into twenty-four pariſhes. A good map of Hadingtonſhire, on a ſcale of two inches to a mile, was publiſhed in 1799 by Mr. Foreſt. In Chalmers's Caledonia, vol. ii. is a full and intereſting account of this county.

HADITA, a town of Curdiſtan, at the conflux of the Altun-ſu with the Tigris; 45 miles S. of Moſul.

HADITH, or HADITSCHEF, a town of Syria, on the Euphrates; 100 miles W.N.W. of Bagdad.

HADLEY, or HADLEIGH, a market-town and pariſh in the hundred of Cosford, and county of Suffolk, is ſeated on the river Breton, at the diſtance of 7 miles W. of Ipſwich, and 64 N.E. of London. The town contained 482 houſes, and 2486 inhabitants, in the year 1801. Camden deſcribes the town as being "famous for the clothing trade" in his time; but at preſent the only manufacture, or trade of the place, is ſpinning of yarn for the Norwich weavers. It is noted by ancient hiſtorians as the burial-place of Guthrum, or Gormo, the Dane, who, on adopting the Chriſtian religion, was preſented by king Alfred with the country of East-Anglia. Gough ſays the inhabitants "pretend to ſhew the tomb of Guthrum, but there is only a long arch with a bouquet on its point in the ſouth wall of the church, of much later date." The ſame author obſerves, that before the rectory-houſe ſtands a venerable brick gate, with two hexagonal towers, built, with the houſe, by William Pikyngham, dean of Stoke college, and rector here about 1490. He alſo founded, in the year 1497, 12 alms-houſes for 24 aged poor perſons, with a chapel. On the adjoining common is a ſtone, with an inſcription, to perpetuate the martyrdom of Dr. Rowland Taylor, rector of this place, who, in 1555, for

> "Defending what was good,
> Upon this plas he left his blood."

This town was anciently incorporated, but its charter was ſurrendered by writ of quo-warranto to king James II. It had formerly two weekly markets, but has now only one, on Mondays, and two annual fairs.

HADLEY, a pleaſant poſt-town of America, in Hampſhire county, Maſſachuſetts, on the E. ſide of Connecticut river, nearly oppoſite to Northampton; 97 miles W. of Boſton. It conſiſts of two long ſtreets, parallel to one another, and to the river, and the townſhip contains 1073 inhabitants.

HADOWTY. See NAGORE.

HADRAMAUT, a province of Arabia Felix, bounded on the W. by Yemen, on the S.E. by the ocean, on the N.E. by Oman, and on the N. by a great deſert. It comprehends a wide extent of country, more eſpecially if, with the Arabians, we include in it the diſtrict of *Mahhra*, which ſee. Hadramaut, like Yemen, exhibits great diverſities of ſoil and ſurface. Some parts of it are dry and deſart; but the hills are extremely fertile, and are interſected by well-watered vales. The inhabitants of this province, like thoſe of Yemen, are divided into Arabs, ſettled in towns, wandering Bedouins, and Kobarts, or highlanders. The religion is a tiſſue of fantaſtic fragments of ſuperſtition; for the prevailing ſect among them is that of the Sunnites. This province, and that of Yemen, conſtituting Arabia Felix, enjoyed, in the remoteſt time, a very extenſive commerce. Its exports conſiſted not only of its own productions, but likewiſe of thoſe of India, which were brought into its harbours, upon the ſhores of the ocean, by veſſels from India; and theſe articles of merchandize were conveyed by land, from the apprehended danger of navigating the Arabic gulf, into Egypt and Syria. The caravans were a ſource of wealth to the whole nation; the inhabitants of the towns gained by purchaſes and ſales, and the Bedouins by hiring out their camels. But ſince the Europeans have diſcovered a different route to India, the trade of South Arabia has neceſſarily declined. However, this province, though deſtitute of the coffee which has been the reſource of Yemen, ſtill carries on ſome trade in its native productions; for theſe ſhips from Maſkat viſit its harbours upon the ocean; the little coffee which it affords, incenſe, gum Arabic, dragon's blood, myrrh, and aloes, are the articles of this trade. The aloes of Soccatra, an iſle belonging to the princes of Hadramaut, has been always in the higheſt eſtimation. The inhabitants have likewiſe ſome trivial manufactures. Yemen is furniſhed from this province with coarſe cloths, carpets, and the knives called "Jumbeu," which are hung from their girdles. But the inhabitants of Hadramaut being averſe to a maritime life, the trade from their ſea-ports is carried on altogether in foreign bottoms. There are ſeveral conſiderable towns in this province, which were better known to the ancients than they are at preſent; ſuch are

are Schibam, Doan, Dafur, Kefchim, Marbat, Hafek, and Ainad, and alfo feveral fea-ports. The Bedouins, and inhabitants of the hills, have here, as well as through other parts of Arabia, a number of independent Scheiks; and the coafts, together with the adjacent country, are fhared among foreigners of higher dignity, whom travellers have called kings, though they take only the title of fcheik, or fultan. The fcheik of Schibam is the moft powerful. The capital of this province is Hadramaut; 360 miles E.N.E. of Mocha.

HADRAN, a town of Perfia, in the province of Adirbeitzan; 132 miles S.W. of Tauris.

HADRIA. See Adria.

HADRIAN. See Adrian.

HADRIANEA, or Hadrinalia, in *Antiquity*, games inftituted by Antonine, at Puzzuoli, in honour of the emperor Hadrian, or Adrian.

There were two forts of Hadrianalia, the one held every year, and the other every five years.

HADRIANISTS, Hadrianistæ, in *Church Hiftory*. See Adrianists.

HADRO, in *Geography*, a town of Curdiftan; 58 miles S.S.W. of Kerkuk.

HADSJAR. See Lachsa.

HAEGT, a town of France, in the department of the Dyle, and chief place of a canton, in the diftrict of Louvain. The place contains 1345, and the canton 10,550 inhabitants, on a territory of 122½ kiliometres, in 11 communes.

HÆMACATE, in *Zoology*, the name of a ferpent found in Afia, the colour of which is bright red: it is a dangerous creature, and is conceived to be the *vipera corallina* of modern naturalifts.

HÆMACHATES, the *blood-coloured agate*, in the *Natural Hiftory of the Ancients*, the name of an agate found at this time in the Eaft Indies, and in fome parts of Germany, and called by Dr. Hill *achates fanguineus variegatus*; or the blood-coloured variegated agate.

It is one of the moft beautiful of the agate kind, and was extremely well characterized by the name the ancients gave it, being always of a ftrong and deep red, like that of blood. Often it is only of this plain and fingle colour throughout the mafs, but more frequently it is found beautifully variegated with a pale blue, and with brown; the blue in this cafe always furrounding the red, and appearing like the ferum which feparates from and floats about the blood, when it has been fome time out of the body; the brown, or hair-colour, is often the bafis, or ground-colour, of the ftone, and the red in fpots only, and variegations, furrounded with this thin blueifh colour; it is very hard, and takes a fine poliih, and is cut into the tops of fnuff-boxes, and other toys, and much valued by our lapidaries.

HÆMAGOGOS, of αιμα, *blood*, and αγω, *I draw away*, the name of a medicinal compofition defcribed in Myrepfus, and intended to bring away the lochia, or forward the menftrual difcharges. It confifts of black hellebore and the fœtid gums, with honey.

HÆMALOPIA, a term derived from αιμα, *blood*, and οπτομαι, *to fee*, and fignifying a morbid affection of the eye, in which every thing appears to have a red colour.

HÆMANTHUS, in *Botany*, from αιμα, *blood*, and ανθος, *a flower*, alluding to the fine red colour of the corolla and involucrum, as well as perhaps to the purple ftains upon the ftalk. Linn. Gen. 160. Schreb. 214. Willd. Sp. Pl. v. 2. 24. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 1. 403. Juff. 55. Tourn. 433. Lamarck. Illuftr. t. 228. Gærtn. t. 11.—Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Spathaceæ*, Linn. *Narciffi*, Juff.

Gen. Ch. *Cal.* Involucrum of feveral, more or lefs coloured, oblong, permanent leaves, furrounding the umbel, with flender linear leaflets between the flowers. *Cor.* of one petal, fuperior, erect; tube fhort, angular; limb in fix deep linear equal fegments, incurved at the points. *Stam.* Filaments fix, awl-fhaped, inferted into the tube, longer than the limb, all equal; anthers oblong, incumbent. *Pift.* Germen inferior; ftyle fimple, as long as the ftamens; ftigma fimple. *Peric.* Berry roundifh, of three cells. *Seeds* folitary, triangular.

Eff. Ch. Involucrum of feveral leaves, many-flowered. Corolla fuperior, in fix deep equal fegments. Berry of three cells. Seeds folitary.

Of this very handfome genus of bulbous plants, the lateft work of Linnæus enumerates but four fpecies. Jacquin has figured and deferibed fix new ones, in his fplendid *Hortus Schoenbrunenfis*, fo that Willdenow defines 14 from thefe and other fources. All except *H. multiflorus*, which comes from Sierra Leone, are natives of the Cape of Good Hope.

1. H. *coccineus*. Linn. Sp. Pl. 412. Curt. Mag. t. 1075. Redout. Liliac. t. 39. (H. africanus; Comm. Hort. v. 2. 127. t. 64. Narciffus indicus puniceus; Ferrari Cult. t. 137. 139. N. indicus ferpentarius; Columna in Hernand Mex. 885. 899. N. indicus, gemino latiore folio; Rudb. Elyf. v. 2. 49. f. 8.)—Leaves two, tongue-fhaped, divaricated, depreffed, flat, fmooth. Umbel denfe, level-topped, fhorter than the involucrum.—An old inhabitant of the gardens of Europe, flowering in the latter part of fummer, after which its leaves appear. It is cultivated in the ftove. The *bulb* is large. The broad dark-green *leaves* lie flat on the ground, fpreading about a foot each way. *Flower-ftalks* folitary, erect, a foot high, fpeckled with dark purple. *Involucrum* of about fix very broad and ftriking fcarlet leaves, rifing above the numerous *flowers*, which are comparatively pale and inconfpicuous. *Berry* pale-red, rarely ripened with us, and then feldom perfecting more than one or two black feeds, though there are always the rudiments of three. The flowers are without fcent.

2. H. *coarctatus*. Jacq. Hort. Schoen. v. 1. 30. t. 57.—Leaves oblong-lanceolate, keeled, fmooth, erect; callous at the tip. Umbel denfe, level-topped, fhorter than the clofe lanceolate-leaved involucrum.—The *leaves* are green, fpotlefs and fmooth, refembling thofe of a *Crinum*, being nearly erect, concave and keeled; their tips red and callous. *Stalk* dotted with red. *Involucrum* deep fcarlet, erect, of feveral lanceolate leaves, pale at the bafe. It flowers in November, the leaves coming out afterwards.

3 H. *puniceus*. Linn. Sp. Pl. 413. Curt. Mag. t. 1315. (H. colchici foliis, perianthio herbaceo; Dill. Elth. 167. t. 140. Trew. Ehret. 14. t. 44.)—Leaves elliptic-oblong, acute, waved, fpreading. Umbel denfe, level-topped, taller than the lanceolate-leaved upright involucrum.—A greenhoufe plant, imported from the Cape, through the hands of the Dutch, and cultivated by Sherard at Eltham about the year 1722. The *root* is thick, and rather tuberous than bulbous. *Leaves* feveral, with fpotted fheathing ftalks, elevating them, like a ftem, feveral inches above the root. *Flower-ftalk* rather taller than the leaf-ftalks, and from a different bud, naked, folitary, fpotted. *Involucrum* green, more or lefs ftained with purple. *Flowers* pale fcarlet, or falmon-coloured, their fegments and ftamens but flightly fpreading. *Berries* crimfon.

4. H. *multiflorus*. Mart. Mill. Dict. n. 8. Nodder Ic. 1. Andr. Repof. t. 318. Curt. Mag. t. 961. (Satyrium e Guinea; Swert. Floril. t. 62. f. 3. Rudb. Elyf. v. 2. 210. f. 3. Orchis e Guinea delata, five fatyrium; Moris. Sect. 12. t. 12. f. 11.)

f. 11.)—Leaves elliptical, ſpreading. Umbel ſpreading, longer than the deflexed lanceolate involucrum. Corolla ſalver-ſhaped. Native of the coaſt of Sierra Leone, from whence it was reſtored to our gardens by the companion of Dr. Afzelius, Francis Borone, who in 1793 ſupplied Meſſrs. Lee and Kennedy with a conſiderable ſtock of the roots, which flowered abundantly, even with a very moderate heat. To bloom ſucceſſively, the plant requires to be kept in a ſtove. Its habit reſembles the laſt, to which its ſynonyms were erroneouſly referred by Linnæus; but the *leaves* are leſs undulated, and the *flowers* far more beautiful, being of a rich deep ſcarlet, forming a large widely expanding umbel, whoſe involucrum is ſmall, pale, and reflexed, like the ſpatha of an *Amaryllis*. The ſegments of the *corolla* ſpread at a right angle with its tube, and the ſtamens are long and divaricated. The *flowers* grow on a rather ſlender ſpotted ſtalk, ſituated, as in the laſt, on the outſide of the leaves, not growing from among them, as drawn by Vallet. This author took his figure from a plant at Paris early in the 17th century, and is copied by thoſe old writers we have cited. In theſe the partial flower-ſtalks look jointed, though originally meant to repreſent ſome flowers as having fallen. This has led profeſſor Willdenow to conſtruct an erroneous ſpecific character.

5. H. *tigrinus*. Jacq. Hort. Schoenbr. v. 1. 29. t. 56.—Leaves two, tongue-ſhaped, divaricated, ſmooth, fringed. Umbel level-topped, denſe, ſhorter than the cloſe, obovate-leaved involucrum.—Native of the Cape of Good Hope, like all the following. It flowered with Jacquin in September. The *bulb* is large and ſcaly. *Leaves* two, ſpreading oppoſitely, as in the firſt ſpecies, but not ſo much depreſſed. They are broad, dark-green, ſmooth, except at the edge, which is denſely fringed, and their baſe externally ſpotted, as in the two laſt. *Flower-ſtalk* compreſſed, beautifully ſpeckled with red. *Involucrum* of about nine upright, obovate, deep-ſcarlet leaves, concealing the flowers, except the tops of their ſtamens and ſtyles. *Corolla* pale red, erect.

6. H. *quadrivalvis*. Jacq. Hort. Schoenbr. v. 1. 30. t. 58.—Leaves two, divaricated, elliptic-oblong, fringed, hairy on the upper ſide. Involucrum of four ſlightly expanding leaves, taller than the cloſe level-topped umbel.—Rather ſmaller than the laſt, and diſtinguiſhed by the rough *foliage*, as well as the few *leaves* of the involucrum, which are pale ſcarlet, with their points expanding, riſing much above the *flowers*, whoſe corolla is of the ſame colour, quite erect, tipped with white.

7. H. *pubeſcens*. Linn. Suppl. 193. Ait. Hort. Kew. v. 1. 404.—Leaves oblong-lanceolate, hairy all over. Umbel roundiſh-level-topped. Limb of the corolla erect.—Introduced into the Kew garden in 1774, by Mr. F. Maſſon. It flowers in Auguſt, and grows naturally in ſandy ground. "The *leaves* are moſtly two, erect, about a ſpan long, ſcarcely an inch broad, flat, ribbed, hairy on both ſides, bluntiſh, contracted at the baſe. *Flower-ſtalk* thread-ſhaped, very ſmooth, reddiſh, three or four inches high, and as thick as a gooſe-quill. *Involucrum* erect, red, of ſix oblong, flat, bluntiſh leaves, an inch and half long and an inch broad. *Flowers* numerous, crowded into a roundiſh-topped umbel, on a level with the involucrum, their *corolla* reddiſh, erect." *Linn. fil. MSS.*

8. H. *ciliaris*. Linn. Sp. Pl. 413. Ait. Hort. Kew. v. 1. 404? (Amaryllis ciliaris; Linn. Suppl. 195.)—Leaves tongue-ſhaped, ſmooth on both ſides, fringed with many rows of hairs pointing forwards.—A ſpecies involved in much confuſion. We have ſeen nothing of the *flowers*, but the *leaves* of the authentic ſpecimen, defined as above, are very different from any thing we find elſewhere deſcribed or figured. Breynius's t. 39. by no means accords with them.

9. H. *albiflos*. Jacq. Hort. Schoenbr. v. 1. 31. t. 59. Curt. Mag. t. 1239.—Leaves elliptical, flat, ſmooth, finely fringed. Stalk hairy, reclining. Involucrum membranous, veiny, of four unequal leaves.—The broad downy-edged *leaves*, white *flowers*, green-veined white *involucrum*, and hairy *flower-ſtalk* diſtinguiſh this from all the preceding. Jacquin makes the *involucrum* ſmooth, Edwards and Gawler in Curt. Mag. fringed. The *corolla* is nearly erect, *umbel* cloſe, *anthers* yellow, *berries* bright ſcarlet.

10. H. *toxicarius*. Ait. Hort. Kew. v. 1. 405. Thunb. Prod. 59. Curt. Mag. t. 1217. (Amaryllis diſticha; Linn. Suppl. 195. Patterſon's Travels, 51, with a very bad plate. —Leaves numerous, two-ranked, lanceolate, glaucous, ſpreading. Involucrum of two leaves, erect. Corolla ſalver-ſhaped. —The only flowers of this plant, known to have been produced in England, were given us in April 1794, from the ſtove of the Hon. Mrs. Barrington at Mongewell, Oxfordſhire. Mr. Sowerby's drawing of them was communicated to the Bot. Mag. by Mr. Lambert, and the original ſpecimen is now before us. The *root* is an ovate bulb, and its juice ſerves the Hottentots to poiſon the arrows, with which they kill antelopes. The *leaves*, common in our ſtoves, are long, glaucous, ſpreading remarkably in two ranks. *Flower-ſtalk* much compreſſed, a foot or more in height, and an inch broad. *Involucrum* more like the ſpatha of an *Amaryllis*, but we preſume the fruit is known to be a *berry*, which places it in the preſent genus. The *flowers* are innumerable, making a denſe umbel; their ſtalks two or three inches long, with many narrow white membranous leaflets among them. *Corolla* very pale roſe-colour, its ſegments horizontal or reflexed, broader than in *H. multiflorus*. *Stamens* of the ſame colour and length.

11. H. *lancifolius*. Jacq. Hort. Schoenbr. v. 1. 31. t. 60. —Leaves few, divaricated, elliptic-lanceolate, ſmooth, fringed with reflexed hairs. Flowers ſalver-ſhaped, taller than the involucrum.—*Bulb* ovate. *Leaves* generally two, widely ſpreading and nearly flat, a ſpan long, an inch and half broad in the middle, tapering at the baſe, dark-green, ſmooth, fringed with reflexed hairs. *Stalk* ſmooth. *Flowers* about ſeven, white with a tinge of red, riſing much above the leaves of the *involucrum*, which are few, erect, oblong, reddiſh, ſpatha-like. The ſegments of the *corolla* ſpread horizontally as in the laſt, and the tube is very ſhort.

12. H. *carinatus*. Mill. Dict. ed. 8. n. 2.—Leaves linear, elongated, keeled.—We know nothing of this but from Miller, who mentions that he received the bulbs from Van Royen of Leyden. He ſays the *root* is like that of *H. coccineus*. *Leaves* three or four, a foot long, or more, not flat, but hollowed like the keel of a boat, more erect than thoſe of *coccineus*, but not quite ſo broad. *Flowers* like that ſpecies, but paler. This deſcription does not much differ from Jacquin's *coarctatus*, ſee n. 2, which may poſſibly be the ſame plant.

13. H. *pumilio*. Jacq. Hort. Schoenbr. v. 1. 32. t. 61. —Leaves linear-lanceolate, upright, ſmooth, naked. Flowers ſalver-ſhaped, taller than the involucrum.—A ſmaller plant than *H. lancifolius*, from which its upright, narrow, ſmooth-edged *leaves* abundantly diſtinguiſh it, though their *flowers* are exactly alike.

14. H. *ſpiralis*. Linn. fil. in Ait. Hort. Kew. v. 1. 405. Thunb. Prod. 58. (Crinum tenellum; Linn. Suppl. 195. Jacq. Ic. Rar. t. 363.)—Leaves briſtle-ſhaped. Stalk thread-ſhaped, ſpiral at the baſe. Involucrum awl-ſhaped, ſhorter than the umbel.—Mr. F. Maſſon ſent this to Kew garden

garden in 1774, where it flowers in September, and is treated as a green-houſe plant. Nothing can be leſs like the other *Hæmanthi*, and there ſeems no reaſon to place it with them except the pulpy *fruit*, which however differs from the reſt in being tricoccous, or three-lobed. The whole habit is very ſlender and thread-ſhaped. *Flowers* ſcarcely above three or four, in a lax umbel, white, funnel-ſhaped, not unlike thoſe of *Anthericum ſerotinum* and others of that genus. *Involucrum* of two ſhort, ſlender, purpliſh leaves. *Stigmas* very diſtinctly three. *Berry* browniſh. The *bulb* is no bigger than a filberd.

Mr. Donn in his *Hortus Cantabrigienſis* mentions, beſides moſt of the above, four ſpecies unknown to us, all from the Cape of Good Hope. Theſe are named by him *H. orbicularis; obliquus; maculatus;* and *undulatus*.

Hæmanthus, in *Gardening*, comprehends plants of the bulbous-rooted, herbaceous, perennial flowering kind; of which the ſpecies cultivated are, the ſcarlet hæmanthus, blood flower, or lilly (H. coccineus); the wave-leaved hæmanthus, blood flower, or baſtard dragon (H. puniceus); and the carinated Cape hæmanthus, (H. carinatus.)

Method of Culture.—In the firſt and third ſpecies the off-ſets being ſparingly afforded, they are of courſe raiſed with ſome difficulty. When the off-ſets are capable of being procured they ſhould be planted in pots of light loamy mould, immediately when the ſtems decay depoſiting them in a dry glaſs frame. The old roots, after they have been taken up, may remain out of the ground until Auguſt, when they ſhould be new potted and placed out in the open air, till they require protection for the winter ſeaſon.

In the ſecond ſort the plants may be readily increaſed by dividing the roots, and planting them out during the early ſpring months, before they ſend forth new ſtems, in pots of light loamy earth. The old roots ſhould alſo be repotted at this ſeaſon.

All the ſorts are likewiſe capable of being raiſed from ſeeds, but eſpecially the ſecond kind, by ſowing them in pots of light ſandy earth, and immediately plunging them into the bark ſtove. As ſoon as the plants appear they ſhould have a pretty free admiſſion of freſh air; and as ſoon as they have attained a good growth, they ſhould be removed into ſeparate pots, and be replunged in the hot-bed. After being properly hardened they may be depoſited in the dry ſtove.

They all require the management of bulbous-rooted plants, little water being given them during the winter ſeaſon, but pretty frequently when the weather is warm, as well as when they are in the flowering ſtate, air being likewiſe pretty freely allowed.

Plants of this nature afford ornament and variety in ſtove collections.

HÆMATEMESIS, in *Medicine*, from αἷμα, *blood*, and ἐμέω, *I vomit*, ſignifies a vomiting of blood.

A diſcharge of blood from the ſtomach is a diſeaſe generally alarming to the patient, and ſometimes attended with conſiderable uneaſineſs and diſtreſs, and occaſionally with danger. From the importance of the organ in the animal economy, and its great connection with life, we ſhould, indeed, be led to ſuppoſe that an hæmorrhage from its veſſels could not occur, without occaſioning very ſerious injury to the conſtitution, or being itſelf the reſult of ſome formidable diſorder of the ſtomach itſelf. But experience altogether invalidates the correctneſs of ſuch a ſuppoſition; and teaches us that, in the great majority of inſtances, a vomiting of blood does not originate in any actual diſeaſe of the ſtomach, but is ſymptomatic of diſorder in ſome other organ, whoſe operations are connected by ſympathy with thoſe of the ſtomach, eſpecially the inteſtines, the liver, the uterus, and other abdominal viſcera; and farther, that the primary diſorder is moſt frequently a ſlight derangement of the bowels or of the liver, which is eaſily removed by medicine. This form of hæmatemeſis we ſhall firſt deſcribe, and afterwards notice the leſs frequent varieties.

The ordinary form of this diſeaſe chiefly attacks females, between the eighteenth and thirtieth year of their age. It is preceded by great languor and oppreſſion, both about the cheſt and the region of the ſtomach; by a ſenſe of fulneſs of the præcordia; by cough, difficulty of breathing, and ſometimes by pain in the breaſt; by loſs of appetite, headache, giddineſs, and diſturbed ſleep. The eye is dull, the countenance is expreſſive of much diſtreſs, the pulſe is feeble, and the bowels are conſtipated. In this ſtate of impaired health, a particular fit of ſickneſs and nauſea is the immediate fore-runner of the attack of the vomiting of blood. The blood brought up is ſometimes florid, and at other times black and grumous; ſometimes it is mixed with a large quantity of mucus, and at others with the remains of the alimentary matters taken into the ſtomach. The quantity of blood brought up at one time varies from a few ounces to a pound or more. The diſtreſſing ſymptoms are relieved by this diſcharge of blood; but they are again aggravated, previouſly to the return of a ſimilar attack of the vomiting.

It is requiſite, when blood is brought up, to aſcertain with accuracy whether it has been diſcharged from the ſtomach or from the lungs: in popular language, the origin of every diſcharge from the cheſt is generally referred to the ſtomach. For this purpoſe the following circumſtances ſhould be inveſtigated. If the blood is brought up manifeſtly by the action of vomiting, without any coughing; if the vomiting has been preceded by ſome ſenſe of weight, anxiety, and pain in the region of the ſtomach; if the blood diſcharged is of a black and grumous appearance; and if it is manifeſtly mixed with other contents of the ſtomach; we can ſeldom have any doubt of the ſource from whence the blood proceeds, and therefore of the exiſtence of the diſeaſe in queſtion. We ſhall have occaſion to notice this ſubject again under the head of Hæmoptysis.

The *cauſes* of this hæmatemeſis have been the ſubject of much ſpeculation. The time of life in which it principally occurs, and the circumſtance of being peculiar to the female ſex, have induced phyſicians to imagine that it is intimately connected with the menſtrual flux, the ſuppreſſion of which has generally been conſidered as the ſole cauſe of the diſeaſe: it has been ſaid to be a hæmorrhage vicarious of the menſes. Dr. Cullen, after ſtating that a plethora in the veſſels of the ſtomach, where there is a general plethoric ſtate of the habit, although it might be ſuppoſed to give riſe to hæmatemeſis, is in fact not found by experience to do ſo; and that ſuch a plethoric ſtate of the ſyſtem is probably induced by the ſuppreſſion of the menſes; is at length compelled to admit that ſome particular (we might as well ſay, unknown) circumſtances of the ſtomach itſelf muſt be ſuppoſed to exiſt which "determine an afflux of blood to that organ, and may therefore occur without any conſiderable or dangerous plethora prevailing in the ſyſtem." The peculiar circumſtances, in this inſtance, he ſuppoſes to be "the connection and conſent which we know to ſubſiſt between the uterus and the whole of the alimentary canal, and eſpecially that principal part of it the ſtomach." (Firſt Lines, par. 1023.)

The obſervations of Dr. Hamilton on this ſubject are more conſiſtent with ſound reaſoning. Admitting the great importance of the uterine ſyſtem in the animal economy, he is inclined to think that too much has been imputed to

the influence of the catamenia in circumſtances of diſeaſe; and that, in explaining theſe circumſtances, we have reaſoned too much on a ſubject that is little underſtood. He farther obſerves, "in the caſe now before us, the cauſe aſſumed, to account for vomiting of blood, proceeds upon limited or miſtaken information. Suſpended menſtruation is not a neceſſary concomitant of hæmatemeſis, which appears when the menſes are regular. I do not know," he adds, "in what proportion of inſtances this is the caſe; but if it is ſo in one inſtance, this one inſtance overturns the theory, does away the vicarious nature of hæmatemeſis, and gives it a place, where I conceive it ought to have one, among idiopathic diſeaſes." (Obſervations on Purgative Medicines, Edinburgh 1805, page 113.)

This cannot but be deemed a ſatisfactory refutation of the vicarious nature of hæmatemeſis; and the fact of the occaſional ceſſation of the diſeaſe, on the re-appearance of ſuſpended catamenia, which was even ſtated by Hippocrates, ("Mulieri ſanguinem evomenti menſtruis erumpentibus ſolutio fit." Aphoriſm, ſect. v. 32.) is eaſily explained on other grounds. The ceſſation of the periodical diſcharge, notwithſtanding the general opinion of females, who attribute almoſt every malady to this ſource, is probably much more frequently a conſequence and a ſign of the ill condition of the general health, than a cauſe of it. (See CHLOROSIS.) The re-appearance of the menſes, therefore, and the ceſſation of the hæmatemeſis, are nearly co-incident, not becauſe the one is the cauſe of the other, but becauſe both are the conſequence of the reſtoration of the general health. It is obvious then, that theoretical diſquiſitions, founded upon ſuch views of the diſorder, muſt have led to practical errors; namely, to the difficult and precarious attempts to reſtore the ſuppreſſed menſes; when obſervation and experience, unſhackled by hypotheſis, would have conducted the practitioner to more efficient means of cure.

Accordingly we find, that under the ordinary method of treatment formerly recommended by practical phyſicians, hæmatemeſis was a diſeaſe of uncertain duration and of very unequal ſeverity; whilſt, under the plan lately introduced by Dr. Hamilton, it is in general ſpeedily removed. Hoffmann affirms, that "a vomiting of blood is, of almoſt all hæmorrhages, the moſt dangerous:" (Medicin. Ration. Syſtem. tom. ii. par. ii.) but he admits at the ſame time that when it ariſes from plethora, or ſuppreſſed evacuations, "we need not deſpair." Dr. Cullen, however, juſtly conſidered this form of hæmatemeſis as "hardly ever a dangerous diſeaſe;" and for ourſelves, we have never witneſſed any ill conſequences reſulting from it, but have always found it yield readily to the method of treatment recommended by Dr. Hamilton, to which indeed our own obſervation had led us previouſly to the appearance of his publication.

The uſual practice adopted for the cure of hæmatemeſis conſiſts in the uſe of refrigerant, or cooling medicines, as they have been called, ſuch as the neutral ſalts, eſpecially nitre, the diluted ſulphuric acid, ſmall doſes of opium, with acidulated drinks and light diet; to which ſome have added the uſe of ſpermaceti and oleaginous matters. If the diſeaſe, notwithſtanding the exhibition of theſe medicines, continued for ſome time, then powerful aſtringents and ſedatives, ſuch as alum, kino, the tincture of muriated iron, digitalis, &c. were reſorted to with the occaſional interpoſition of a gentle laxative, ſuch as the caſtor oil. (See Thomas's Modern Practice of Phyſic.) Dr. Cullen recommended the uſe of the ordinary remedies employed in the caſe of ſuppreſſed catamenia; and Hoffmann likewiſe preſcribed the employment of mild emmenagogues, frequent emmenagogue glyſters and bleeding in the foot, when the bloody vomiting aroſe from ſuppreſſions or obſtructions of the menſes. The ſame able phyſician alſo adviſed that, if the patient be plethoric, bleeding from the arm, cautiouſly proportioned to the age, ſtrength, and degree of repletion of the individual, ſhould be reſorted to in the paroxyſm; and where there was much heat with ſtrong pulſe, he uſed free dilution with watery liquids, containing nitre and ſyrup of poppies, as well as emollient glyſters with nitre, with a view to relax the ſpaſms of the inteſtines, and to procure a derivation of the humours from the ſtomach. In order to prevent a recurrence of the vomiting, he preſcribed "half a drachm of rhubarb twice a-week at bed-time, either by itſelf or with crabs'-eyes, or half a grain of camphor for common drink, pure water in which iron has been quenched, or acidulated whey; and for tea an infuſion of veronica, knot-graſs, milfoil tops, liquorice, and fennel ſeeds." He cautions us to be wary in the uſe of opium in all vomitings of blood, from whatever cauſe, and likewiſe of aſtringent and vitriolic medicines; which, he ſays, though they reſtrain the hæmorrhage, endanger the occurrence of inflammation, and even of dropſy. (Hoffmann, loc. cit.)

The experience of Dr. James Hamilton, in the Royal Infirmary at Edinburgh, led him to the knowledge of the connection of hæmatemeſis with a conſtipated ſtate of the alimentary canal, and of the conſequent facility of removing the diſeaſe by the exhibition of cathartics. After having adopted this mode of treatment during a period of ten years, Dr. Hamilton thus ſtates his opinion of its efficacy. "I have followed the practice, which this caſe ſuggeſted in the inſtances of the ailment which I have ſince met with; and my ſucceſs has been ſo uniform, that I now lay it down as a certain poſition, that the proper exhibition of purgative medicines affords ſure and effectual means of removing hæmatemeſis, the ſubject of this chapter." He goes on to remark, "the purgatives which I have uſed in theſe caſes have never excited vomiting; and what may be thought ſingular, I have never been able to aſcertain the preſence of blood in the fæces. As the ſtrength of patients labouring under this vomiting of blood is generally pretty entire, we need not dread full purging; but this effect is not wanted; if we unload the bowels we accompliſh the cure. The fæces which are brought off are copious, unnatural in colour, conſiſtence, and ſmell, as they generally are after long remora, the conſequence of obſtinate and protracted coſtiveneſs. The different circumſtances which not only expoſe women to coſtiveneſs more readily than men; but when it does occur, to a more obſtinate kind of it, as already noticed, may explain why they are excluſively the ſubjects of the diſeaſe." (Loc. cit. p. 116.) The medicines which Dr. Hamilton employed with a view to empty the bowels were various; combinations of calomel and jalap, aloetic pills, neutral ſalts, &c. occaſionally aided by the uſe of injections: and as far as our own experience goes, the nature of the purgative, provided it will agree with the ſtate of the ſtomach, and is proportioned to the ſtrength of the patient, and to the neceſſity of evacuation, is a matter of ſecondary importance.

This practical fact being aſcertained, the rational inquirer will not aſk for any theoretical explanation of it. Whether we may ſuppoſe the loaded bowels to impede the hepatic and abdominal circulation, and thus to occaſion a venous plethora in the ſtomach and inteſtines; or whether the languid circulation in theſe parts, and the ſlow action of the bowels, may be alike the conſequence of the general languor of the ſyſtem; or whether any other hypotheſis may be reſorted to, the value of the practical fact is neither diminiſhed nor augmented.

Having diſcuſſed the ordinary form of hæmatemeſis at ſome

ſome length, we have only a few words to add relative to ſome other modifications of the diſeaſe, which depend upon more ſerious diſorder of the ſtomach itſelf, of other organs, or of the ſyſtem at large. Succeſs in the cure of theſe varieties of bloody vomiting is doubtful in the extreme, and very difficult to be attained; for the conſtitution itſelf is undermined in theſe caſes, by acute diſeaſe, or by previous irregularities and intemperance; in addition to the local miſchief.

The organic derangements of the ſtomach, which are accompanied by vomiting of blood, are thoſe ariſing from wounds or other mechanical injury to its ſtructure, which are generally ſpeedily fatal. Theſe are included in the ſecond ſpecies of Sauvages, Hæmatemeſis *traumatica;* to which may be added the ninth, or H. *cholerica*, as far as regards its origin from corroſive poiſon ſwallowed; and the fourth, or H. *ab hyrudine*, in which the internal coat of the ſtomach has been wounded by a leech, ſwallowed in drinking ditch water. (Riverius, Cent. iv. Obſ. 26.) In cancer and ſcirrhus of the ſtomach a blackiſh matter, reſembling the grounds of coffee, is commonly ejected by vomiting; but as this is not in a fluid ſtate it can ſcarcely be denominated hæmatemeſis.

Morbid enlargements of the neighbouring viſcera, the ſpleen, pancreas, and liver, (ſee Sauvages, ſpec. 6, 7, and 13.) aneuriſm of the aorta, (ſpecies 2.) and compreſſion of that artery, (ſpec. 11.) have all been aſſigned as occaſional cauſes of hæmatemeſis. In the records of phyſic, Dr. Cullen obſerves, there are many inſtances of vomitings of blood, which were accompanied with a tumified ſpleen, which had compreſſed the vas breve, and thereby prevented the return of venous blood from the ſtomach. It is alſo poſſible, that an obſtruction of the liver, reſiſting the free motion of the blood in the vena portarum, may ſometimes interrupt the free return of the venous blood from the veſſels of the ſtomach, and thereby occaſion a vomiting of blood; but the inſtances of this are neither ſo frequent nor ſo clearly explained as thoſe of the former caſe. (Firſt Lines, par. 1027—28.) In the *morbus niger* of authors, and the *melæna* of Sauvages, the black and grumous blood is ſometimes thrown out by vomiting, as well as diſcharged downwards, and is conſidered as originating in a venous plethora in the inteſtinal canal, connected with obſtructed viſcera. (See Melæna.) This forms the twelfth ſpecies of Sauvage, or H. *atra*.

There are two or three conditions of the conſtitution in which hæmatemeſis is liable to occur, and in which it is to be deemed a hopeleſs ſymptom. The firſt of theſe is the laſt ſtage of acute fevers, in which ſpontaneous hæmorrhage takes place from different parts of the body, and is uſually conſidered as the moſt decided ſymptom of the malignancy and putreſcency of the diſeaſe. In typhus, ſcarlet-fever, ſmall-pox, &c. this ſort of hæmorrhage occaſionally cloſes the ſcene. Hence the aphoriſm of Hippocrates, "qui ſanguinem vomunt, ſi quidem ſine febre, ſalutare; ſi verò cum febre, malum." (Sect vii. Aph. 37.) The other conſtitutional condition is that which is found in ſcurvy, and in the *purpura hæmorrhagica*, *hæmorrhœa petechialis*, or *purples*, as the diſeaſe has been variouſly denominated. In the higheſt degree of theſe maladies, blood flows from every part of the body, internal and external, where the cuticle or inveſting membrane is delicate and thin, and hæmorrhage from the ſtomach is one form of the diſcharge.

Laſtly, we may obſerve, that Sauvages has included in his account a pretended hæmatemeſis, (H. *ſimulata*. ſpec. 10.) in which a deception was practiſed, even upon the medical attendant, by a girl who was confined in a convent and was deſirous of being ſent out. She vomited ſeveral pounds of blood, for ſeveral days even in the preſence of the phyſician: but it was at length diſcovered that ſhe ſwallowed bullock's blood, which was clandeſtinely conveyed to her daily. (Sauvages Noſol. Method. Claſs ix. genus 4.)

HÆMATION, a word uſed among the *Ancients*, for a ſort of reddiſh garon, made of the inteſtines and blood of fiſhes macerated in ſalt.

HÆMATITES, from αιμα, *blood*, in *Natural Hiſtory*, the *blood-ſtone;* a kind of ruddy mineral ſubſtance; thus called, either on account of its reſembling dry curdled blood, or of its reputed faculty of ſtaunching blood.

Pliny reckons five kinds of blood-ſtone; *viz.* the *Ethiopic*, *androdamas*, the *Arabic*, the *elatites* or *miiittes*, and the *ſchiſtos;* beſides that commonly called in his time the *magnes hæmatites*, from the property it hath of attracting iron.

Theſe five ſorts differ chiefly in point of hardneſs: the beſt, according to Dioſcorides, is that which is friable, hard, black, and ſmooth, without either gritty parts, or veins. That commonly uſed by the painters is factitious, being made of Armenian bole, and other drugs.

The common native, or the foſſil kind, comes from Egypt, Bohemia, &c. This is of various figures; ſpherical, ſemi-ſpherical, pyramidal, or cellular; compoſed of ſmall pyramids, the apices of which appear, in a tranſverſe ſection, in the centre. It contains a large portion of iron; but the iron is obtained with ſuch difficulty, and is of ſo bad a quality, that this ore is not commonly ſmelted. This ſtone, when expoſed to a moderately ſtrong fire, falls by degrees into ſcales; and in this ſtate is attracted by the magnet, and gives out its iron to acids. It has divers uſes in medicine; being held cooling and aſtringent, and, in that quality, preſcribed in hæmorrhages and uterine obſtructions. It is given in ſubſtance, in form of a fine powder, from one ſcruple to three or four, for a doſe. It is alſo uſed in diſtemperatures of the eyes; but pure iron, or the preparations of iron, muſt be preferable to this ſtone in the ſame intention.

The gilders uſe it for burniſhers to poliſh their metals. Bauſchius has an expreſs treatiſe on the lapis hæmatites.

HÆMATOCELE, in *Surgery*, denotes a ſwelling of the ſcrotum, or of the ſpermatic cord, cauſed by blood. The term is derived from the Greek αιμα, *blood*, and κηλη, *a tumour*.

In this article we have little more to do than inſert Mr. Pott's account of the diſeaſe, of which no earlier, nor any later author has treated with equal ability. He begins with pointing out the importance of making diſtinctions in the complaint, as without them it cannot be properly underſtood, and an ill-founded and haſty prognoſis is apt to be given.

Mr. Pott remarks, that "the diſeaſe, properly called hæmatocele, is of four kinds; two of which have their ſeat within the tunica vaginalis teſtis; one within the albuginea; and the fourth in the tunica communis, or common cellular membrane, inveſting the ſpermatic veſſels.

"In paſſing an inſtrument, in order to let out the water from an hydrocele of the vaginal coat, a veſſel is ſometimes wounded, which is of ſuch ſize, as to tinge the fluid pretty deeply at the time of its running out. The orifice becoming cloſe, when the water is all diſcharged, and a plaſter being applied, the blood ceaſes to flow from thence, but inſinuates itſelf partly into the cavity of the vaginal coat, and partly into the cells of the dartos; making, ſometimes, in the ſpace of a few hours, a tumour nearly equal in ſize to the original hydrocele. This is one ſpecies.

"It ſometimes happens, in tapping an hydrocele, that although the fluid diſcharged by that operation be perfectly

clear and limpid, yet, in a very ſhort ſpace of time (ſometimes in a few hours), the ſcrotum becomes as large as it was before, and palpably as full of a fluid. If a new puncture be now made, the diſcharge, inſtead of being limpid (as before), is now either pure blood, or very bloody. This is another ſpecies; but, like the preceding, confined to the tunica vaginalis.

"The whole vaſcular compages of the teſticle is ſometimes very much enlarged, and at the ſame time rendered ſo lax and looſe, that the tumour produced thereby has, to the fingers of an examiner, very much the appearance of a ſwelling compoſed of a mere fluid, ſuppoſed to be ſomewhat thick or viſcid. This is in ſome meaſure a deception; but not totally ſo. The greater part of the tumefaction is cauſed by the looſened texture of the teſtis; but there is very frequently a quantity of extravaſated blood alſo.

"If this be ſuppoſed to be an hydrocele, and pierced, the diſcharge will be mere blood. This is a third kind of hæmatocele; and very different, in all its circumſtances, from the two preceding. The fluid is ſhed from the veſſels of the glandular part of the teſticle, and contained within the tunica albuginea.

"The fourth conſiſts in a rupture of, and an effuſion of blood from, a branch of the ſpermatic vein, in its paſſage from the groin to the teſticle; in which caſe, the extravaſation is made into the tunica communis, or cellular membrane inveſting the ſpermatic veſſels."

Theſe four, Mr. Pott has ſeen ſo diſtinctly and perfectly, that he has not the ſmalleſt doubt concerning their exiſtence, and of their difference from each other.

He next ſtates, that "the tunica vaginalis teſtis, in a natural and healthy ſtate, is a membrane, which, although firm, is of no great thickneſs. It is white, or rather of a reddiſh white colour, and its blood-veſſels are (in a healthy ſtate) no more apparent to the eye than are thoſe of the tunica albuginea; but when it has been long or much diſtended, it thereby becomes thick and tough, and the veſſels (eſpecially thoſe of its inner ſurface) are ſometimes ſo large as to be very viſible, and even varicoſe. If one of theſe lies in the way of the inſtrument wherewith the palliative cure is performed, it is ſometimes wounded; in which caſe, as I have already obſerved, the firſt part of the ſerum which is diſcharged is pretty deeply tinged with blood.

"Upon the collapſion of the membranes, and of the empty bag, this kind of hæmorrhage generally ceaſes, and nothing more comes of it. But it ſometimes happens, either from the toughneſs of the tunic, or from the varicoſe ſtate of the veſſel, that the wound (eſpecially if made by a lancet) does not immediately unite, but continues to diſcharge blood into the cavity of the ſaid tunic, thereby producing a new tumour, and a freſh neceſſity of operation."

Mr. Pott calls this the firſt ſpecies of hæmatocele, which evidently conſiſts in a wound of a veſſel of the vaginal tunic.

"Upon the ſudden diſcharge of the fluid, from the bag of an over-ſtretched hydrocele, and thereby removing all counter-preſſure againſt the ſides of the veſſels, ſome of which are become varicoſe, one of them will ſometimes, without having been wounded, burſt. If the quantity of blood ſhed from the veſſel ſo burſt be ſmall, it is ſoon abſorbed again; and, creating no trouble, the thing is not known. But if the quantity be conſiderable, it, like the preceding, occaſions a new tumour, and calls for a repetition of the operation." This is the ſecond ſpecies, "which, like the firſt, belongs entirely to the vaginal coat, and has no concern either with the teſticle, or with the ſpermatic veſſels. In both the bag, which was full of water, becomes in a ſhort ſpace of time diſtended with blood, which blood, if not carried off by abſorption, muſt be diſcharged by opening the containing cyſt; but in neither of theſe can caſtration (though ſaid to be the only remedy) be ever neceſſary. The mere diviſion of the ſaeculus, and the application of dry lint to its inſide, will in general, if not always, reſtrain the hæmorrhage, and anſwer every purpoſe for which ſo ſevere a remedy has been preſcribed. The other two are indeed of more conſequence; they intereſt either the teſticle itſelf, or the veſſels by which it is ſupplied with blood, and rendered capable of executing its office, and are ſometimes not curable but by removal of the part.

"One of theſe is ſeated within the tunica albuginea of the teſticle; the other in the tunica communis of its veſſels. They are neither of them very frequent; but when they do happen they call for all our attention.

"If blood be extravaſated within the tunica albuginea, or proper coat of the teſticle, in conſequence of a great relaxation, and, as it were, diſſolution of part of the vaſcular compages of that gland, and the quantity be conſiderable, it will afford or produce a fluctuation, to the hand of an examiner, very like to that of an hydrocele of the tunica vaginalis; allowing ſomething for the different denſity of the different fluids, and the greater depth of the former from the ſurface.

"If this be miſtaken for a ſimple hydrocele, and an opening be made, the diſcharge will be blood; not fluid, or very thin; not like to blood circulating through its proper veſſels, but dark and duſky in colour, and nearly of the conſiſtence of thin chocolate (like that which is moſt frequently found in the imperforate vagina). The quantity diſcharged will be much ſmaller than was expected from the ſize of the tumour, which ſize will not be conſiderably diminiſhed. When this ſmall quantity of blood has been ſo drawn off, the teſticle will, upon examination, be found to be much larger than it ought to be, as well as much more looſe and flabby. Inſtead of that roundneſs and reſiſtance ariſing from an healthy ſtate of the gland within its firm ſtrong coat, it is ſoft, and capable of being compreſſed almoſt flat, and that generally without any of that pain and uneaſineſs which always attend the compreſſion of a ſound teſticle. If the bleeding ceaſes upon the withdrawing the cannula (ſuppoſing a trochar to have been uſed) and the puncture cloſes, a freſh accumulation of the ſame kind of fluid is ſoon made, and the ſame degree of tumefaction is produced as before the operation. If the orifice does not cloſe, the hæmorrhage continues, and very ſoon becomes alarming.

"In the two preceding ſpecies, the blood comes from the tunica vaginalis, the teſtis itſelf being ſafe and unconcerned, and the remedy is found by opening the cavity of the ſaid tunic; but in this the hæmorrhage comes from the ſubſtance of the teſticle—from the convolutions of the ſpermatic artery within the tunica albuginea. The diviſion of the vaginal coat can here do no good; and an inciſion made into the albuginea can only increaſe the miſchief. The teſticle is ſpoiled or rendered uſeleſs by that kind of alteration made in it previous to the extravaſation; and caſtration is the only cure which a patient in ſuch circumſtances can depend upon.

"The laſt ſpecies of this diſeaſe ariſes from a burſting of a branch of the ſpermatic vein between the groin and ſcrotum, in what is generally known by the name of the ſpermatic proceſs. This, which is generally produced by great or ſudden exertions of ſtrength, feats of agility, &c. may happen to perſons in the beſt health, whoſe blood and juices are in the beſt order, and whoſe genital parts are free from blemiſh or diſeaſe.

"The effuſion or extravaſation is made into the cellular membrane,

membrane, which inveſts and envelopes the ſpermatic veſſels, and has ſomething the appearance of a true hernia. When the caſe is clear, and the extravaſated blood does not give way to diſcutient applications, the only remedy is to lay the tumour fairly open through its whole length. If the veſſel or breach be ſmall, the hæmorrhage may be reſtrained by mere compreſſion with dry lint, or by the uſe of ſtyptics; but if it be large, and theſe means do not ſucceed, the ligature muſt be made uſe of." Pott's Chirurgical Works, voll. ii.

HÆMATOCHYSIS, a word derived from αιμα, *blood*, and χεω, *to pour out*; an effuſion of blood.

HÆMATOMPHALOCELE, a tumour at the navel, containing blood. The term is deduced from αιμα, *blood*, ομφαλος, *the navel*, and κηλη, *a tumour*.

HÆMATOPUS, in *Ornithology*, a genus of the Grallæ order, diſtinguiſhed by having the bill compreſſed with the tip equal and cuneated; noſtrils linear; tongue about one-third the length of the bill; and the feet three-toed, cleft, and formed for running. The only ſpecies of this genus at preſent known is that called Oſtralegus by Linnæus.

Ostralegus. Bill orange; head, neck, and ſhoulders black; wings and tail black and white, body beneath white; legs red. Linn. &c. *Marſpitt*, *ſtrandſkjura*, Linn. Fn. Suec. *Tirma*, Martin. *Scolopax pica*, Scop. *L'huitrier*, Briſſ. *Sea pie*, Ray. *Pied oyſter-catcher*, Donov. Br. Birds, &c.

This bird is an inhabitant of almoſt every ſhore throughout Europe, and alſo extends to America, differing, however, in ſome countries, in being more or leſs variegated with white, and in ſometimes being deſtitute of any intermixture of that colour. The pied variety is more peculiar to England, and other European countries; thoſe entirely black are met with in the north of Europe, in ſome parts of America, in New Zealand, Terra del Fuego, and Van Diemen's land.

Both varieties of the ſpecies are excluſively confined to the ſhores of the ſea, its food conſiſting of marine worms, cruſtaceous animals, inſects, and the various kinds of littoral ſhell-fiſh, as the limpet, muſcle, and oyſter.

In England this bird is known by the name of ſea-pie, and perhaps not leſs generally by that of oyſter-catcher, the latter alluding to the facility with which it contrives to open the ſhell of the oyſter, and extract the fiſh. This ſingular feat is not unfrequently accompliſhed by force, the bird violently thruſting its laterally compreſſed bill between the valves, and burſting the ſhell aſunder, as if effected by means of a knife: in like manner it opens the muſcle, or removes the limpet from the rock, and devours the inhabitant. It is a wily, artful bird, and is often obſerved to have recourſe to ſtratagem as well as force to obtain its prey; the oyſter eſpecially, as the ſhells of thoſe are oftentimes ſtrong enough to withſtand the violence of its attacks; in this caſe it deſiſts, waiting patiently for the convenient moment when the oyſter gapes, and cautiouſly approaching, drops or inſerts a pebble between the valves, which preventing them from again cloſing, the animal within becomes an eaſy prey.

During winter theſe birds are ſeen in large flocks; in the ſummer ſeaſon they uſually appear in pairs. The female lays four or five eggs on the bare ground, above high water mark: the colour of the eggs is greeniſh-grey, varied with ſpots or blotches of black. The total length of the adult bird is ſixteen inches and a half.

HÆMATOSIS, formed of αιμα, *blood*, in *Medicine*, the action whereby the chyle is converted into blood; called alſo *ſanguification*.

The chief of the vital actions are the chyloſis and hæmatoſis.

HÆMATOXYLUM, in *Botany*, from αιμα, *blood*, and ξυλον, *wood*; becauſe of the dark-red colour of the wood, for which it is uſeful in dyeing. Log-wood.—Linn. Gen. 210. Schreb. 280. Willd. Sp. Pl. v. 2. 547. Mart. Mill. Dict. v. 2. Juſſ. 348. Lamarck. Illuſtr. t. 340. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coloured; tube very ſhort, cup-ſhaped, fleſhy, permanent; limb in five deep, ſpreading, oblong, obtuſe, deciduous ſegments, of which the four uppermoſt are equal, the lower one rather the longeſt. *Cor.* Petals five, lanceolate, broader upwards, obtuſe, veiny, ſpreading, nearly equal, inſerted into the calyx, and larger than its ſegments. *Stam.* Filaments ten, awl-ſhaped, erect, unequal, ſcarcely longer than the corolla, inſerted into the calyx, their lower part hairy on the inſide; anthers oval, ſmall. *Piſt.* Germen ſuperior, oblong, ſcimitar-ſhaped, compreſſed; ſtyle capillary, curved at the point, longer than the ſtamens; ſtigma funnel-ſhaped. *Peric.* Legume lanceolate, flat, obtuſe, of one cell, bordered at each edge with a thickiſh future, which does not ſeparate, but opening by a longitudinal laceration along the middle of each valve, ſo as to divide itſelf into two unequal boat-like parts. *Seeds* few, oblong, compreſſed, furrowed, affixed to one of the futures.

Eſſ. Ch. Calyx in five deep deciduous ſegments. Petals five. Legume lanceolate, of one cell, opening along the middle of its valves. Seeds ſeveral.

1. H. *campechianum*. Linn. Sp. Pl. 549. Jacq. Obſ. faſc. 1. 20. Woodv. Med. Bot. t. 17.—The only ſpecies hitherto diſcovered. Native of South America, eſpecially at Campeachy, in the bay of Honduras, from whence it was brought to Jamaica in 1715, in order to be propagated there for exportation. This ſcheme does not appear to have anſwered, though the plant thrives there in ſwampy ground. It is known by the name of Logwood, Campeachy-wood, or Blood-wood, and is principally uſed in Europe for dyeing, though, from its aſtringent quality, not totally uſeleſs as a corroborant of the inteſtines after diarrhœas, and even dyſenteries. It gives a red colour to the ſtools, and ſometimes the urine. The taſte of the wood is ſweetiſh, the ſmell peculiar, not without a faint fragrance. Its colour is a deep purpliſh red, which it communicates to water or ſpirit. This wood is brought to Europe in logs about a yard long, of a ſinuous and twiſted appearance, and very heavy. Before it can be uſed, it is ground, or rather cut and bruiſed, by a mill on purpoſe, and gains conſiderably in bulk. The plant is ſaid to have been cultivated in England 70 years ago by Miller, who mentions it as thriving well, but Dr. Woodville aſſures us he ſought in vain for a ſpecimen in moſt of the hot-houſes about London, nor have we ever ſeen any growing.—The *tree* is ſmall and crooked, with a dark rough bark, the branches armed with ſolitary, axillary, prominent thorns. *Leaves* abruptly pinnate, compoſed of four or five pair of rigid, very ſmooth and ſhining, wedge-ſhaped, emarginate, entire leaflets. *Flowers* reddiſh-yellow, numerous, in axillary ſpikes, longer than the leaves, either ſolitary or in pairs, appearing in March.

HÆMATURIA, in *Medicine*, from αιμα, *blood*, and ουρον, *urine*, ſignifies the paſſing of bloody urine, *mictus cruentus*.

A diſcharge of blood from the urinary paſſages is ſeldom, if ever, an idiopathic diſeaſe; but is occaſioned, perhaps always, by ſome injury to the parts, or by ſome other diſeaſe affecting them, of which the hæmaturia is a conſequence

and

and a ſymptom. It has been alleged, indeed, by ſome writers, that a ſpontaneous or idiopathic hæmaturia occaſionally occurs in plethoric conſtitutions; in which it has been conſidered as a ſalutary evacuation, originating in the local congeſtion or plethora of the kidnies. (See Sauvages Noſol. Meth. Claſs. ix. Gen. v. Spec. 1. Hæmaturia *ſpontanea*: alſo Juncker, Tabul. 10. in Aph. 25.) Such inſtances, however, are at leaſt extremely rare, and have not occurred to the obſervation of Dr. Cullen and other experienced phyſicians. Dr Cullen thinks it probable that the obſervations, which have been recorded, may have been fallacious; "for I have frequently obſerved," he ſays, "an hæmaturia without ſymptoms of other affection of the kidney or urinary paſſages being, for the time, preſent; whilſt, however, fits of a *nephralgia calculoſa* having before, or ſoon after, happened, rendered it to me ſufficiently probable, that the hæmaturia was owing to a wound made by a ſtone preſent in ſome part of the urinary paſſages." (Firſt Lines, par. 1034.)

The moſt frequent cauſe of hæmaturia, is the preſence of a ſtone or concretion in ſome part of theſe paſſages; and the diſcharge of blood, in ſuch caſes, is manifeſtly owing to the wounding of the internal ſurface of the pelvis of the kidney, of the ureter, or of the bladder, occaſioned by this hard and often irregularly ſhaped ſubſtance. This is the Hæmaturia *calculoſa*, ſpecies 5, of Sauvages. The attending ſymptoms will enable us to aſcertain, without much difficulty in general, whether the ſource of the blood is in the kidney or ureter, or in the bladder itſelf. If a calculus is preſent in the pelvis of the kidney, or in the ureter leading to the bladder, there is generally a moſt ſevere pain fixed in one ſide of the loins, and ſhooting in the direction of the ureter to the bladder; in men it is accompanied with a painful retraction of the teſticle of the ſame ſide, and in women with a numbneſs extending down the thigh; and during the ſeverity of the pain, there is generally a nauſea in the ſtomach, and even vomiting. See NEPHRALGIA.

In ſuch caſes, the blood diſcharged with the urine is ſometimes of a florid colour, but for the moſt part it is of a dark hue. The whole of it is ſometimes diffuſed or diſſolved, and therefore entirely ſuſpended, in the urine; but if it is in any large quantity, a portion of it is depoſited to the bottom of the veſſel in which it is contained. On different occaſions it puts on other appearances. Thus when blood, poured out in the kidney, has happened to ſtagnate for ſome time in the ureters or bladder, it is ſometimes coagulated, and the coagulated part is afterwards broken down into a grumous maſs of a dark or black colour, and therefore gives the ſame colour to the urine voided; or if the quantity of broken down blood is ſmall, it gives only a browniſh urine reſembling coffee. It ſometimes alſo happens, that the blood, ſtagnating and coagulating in the ureters, takes the form of theſe veſſels, and is therefore voided under the appearance of a worm; and if the coagulated blood happens to have the gluten ſeparated from the red globules, theſe worm-like appearances have their external ſurface whitiſh, and the whole ſeemingly forming a tube containing a red liquor. (Cullen.) "Hæc vermiformia corpora vidi;" ſays Sauvages, "ſunt tubuli pellucidi ſero rubro pleni." Theſe coagula have ſometimes been miſtaken for worms, as by Platerus probably, in the caſe of *lumbricorum miſtus*, lib. iii. Dr. Cullen ſays that he had ſometimes obſerved the blood, which had ſeemingly been coagulated in the ureter, come away in an almoſt dry ſtate, reſembling the half-burnt wick of a candle.

Theſe are the ſeveral appearances of the blood, voided in the hæmaturia calculoſa, when it proceeds eſpecially from the kidney or ureter, and many of the ſame appearances are obſerved, when the blood proceeds only from the bladder when a ſtone is lodged there. The ſymptoms in this caſe, however, are conſiderably different. The ſigns of a ſtone in the bladder will have commonly preceded the hæmaturia; and the abſence of acute pain in the lumbar region, extending obliquely acroſs to the bladder, the ſenſe of weight and pain in the ſeat of this organ, the ſudden ſtoppage of the urine, while paſſing in a full ſtream, &c. (ſee STONE), will contribute to point out the ſource of the hæmorrhage. It may happen, indeed, as Dr. Cullen has remarked, that, when a quantity of blood from the kidney or ureter is coagulated in the bladder, and is therefore with difficulty got rid of, the pain and uneaſineſs may appear to be chiefly in the bladder, though it contains no ſtone; but in ſuch caſe, he obſerves, the antecedent ſymptoms will commonly diſcover the nature of the diſeaſe.

The *cure* of hæmaturia *calculoſa* can only be effected by the removal of the calculus, which excites the hæmorrhage, and its return prevented by the remedies which ſeem to obviate the formation of the uric acid, of which the calculi or concretions commonly conſiſt. Theſe are chiefly alkaline and abſorbent medicines. But as the treatment of the diſeaſes, of which the hæmaturia is a ſymptom, is amply detailed under their reſpective heads, a repetition of it is unneceſſary here. (See GRAVEL, NEPHRALGIA, and STONE.) It may be ſufficient to add, that every ſpecies of irritation that can affect the kidnies or ureters muſt be carefully avoided; and that of ſuch irritation none is more frequent or more conſiderable than the preſence of hardened fæces in the colon, which of courſe muſt be removed by the frequent uſe of gentle laxatives.

Hæmaturia occaſionally happens from the application of external violence (conſtituting the H. *violenta*, and H. *traumatica*, of Sauvages, ſpec. 2, and 13.); as from a kick or blow in the loins, or (as we once obſerved) in the ſide of the belly; or from the violent or long continued exerciſe of the muſcles incumbent on the kidnies, as in riding on horſeback. The former of theſe circumſtances are often immediately followed by a diſcharge of pure blood from the urinary paſſages. In ſuch caſes, the rigid adoption of the antiphlogiſtic regimen becomes immediately neceſſary; and if any tendency to inflammation in the wounded organ appears, even a farther depletion of the blood-veſſels may be requiſite. See NEPHRITIS.

Under the head of hæmaturia from violence, Sauvages includes the variety of the diſeaſe, which occurs in conſequence of taking certain acrid ſubſtances, which particularly paſs off by the urinary canals, and which, by inflaming and ſwelling the neck of the bladder, bring on a rupture of the over-diſtended veſſels, and give occaſion to a bloody urine. Cantharides, turpentines, and acrid diuretic medicines, are liable to produce this effect. In theſe inſtances, the diſorder will be removed by omitting the uſe of theſe medicines, by the free exhibition of thin, diluent, and mucilaginous liquors, by camphor and other anodynes, as in caſes of ſtrangury in general.

Inſtances of hæmaturia have alſo been mentioned by authors originating from a ſuppreſſion of the menſtrual and hæmorrhoidal diſcharges; but theſe are at leaſt extremely rare. The examples of bloody urine connected with the ſcorbutic or petechial diatheſis, whether independent of fever, or occurring in the latter ſtage of typhus, ſmall-pox, &c. are commonly accompanied by hæmorrhages from other parts, and denote, not any particular diſeaſe of the urinary

organs,

organs, but that looſe and uncoagulating condition of the blood, which is commonly aſſumed as a mark of its putreſcent ſtate. See HÆMORRHÆA.

The ſtate of the urine, which is coloured by the red juices of ſome particular fruit, as the ficus opuntiæ, has given riſe to a ſpecies in the catalogue of Sauvages, by a ſort of ſoleciſm called Hæmaturia *deceptiva*. The ſame obſervation is applicable to his H. *ſpuria*, and H. *lateritia*, in both of which there is no blood in the urine; but this fluid is of a deep red colour, ſo as to give a ſuſpicion of its being tinged with blood. This occurs in ſome diſeaſes, and it is important in many caſes to determine, whether the red colour of the urine be from blood preſent in it, or from a ſuperabundance or altered condition of the ſalts and oils, which are conſtituent parts of the urine. According to Dr. Cullen, the queſtion may commonly be decided by the following conſiderations:

When any conſiderable quantity of blood is voided with the urine, there is always a portion of it depoſited at the bottom of the veſſel; and in ſuch a caſe, there will be no doubt in attributing the colour of the urine floating above, to ſome part of the blood diffuſed in it. The queſtion, therefore, can only occur, when no ſuch depoſition appears; and when the blood, that may be ſuppoſed to be preſent, is diſſolved or diffuſed, and therefore entirely ſuſpended in the urine. In this caſe the preſence of blood may be commonly known; 1ſt, by the colour which blood imparts to urine, and which a little experience will enable moſt perſons to diſtinguiſh. 2dly. By the circumſtance, that the preſence of blood always diminiſhes the tranſparency of the urine with which it is mixed; while the moſt high-coloured urine ſeldom loſes its tranſparency, at leaſt when it is recently voided. 3dly. When urine has blood mixed with it, it tinges a piece of linen dipt into it with a red colour, which the higheſt coloured urine without blood never does. 4thly. High-coloured urine, without blood, upon cooling and remaining at reſt in a veſſel, almoſt always depoſits a lateritious ſediment, and if bloody urine makes a depoſit of part of its blood in this way, the difference may be diſcerned by heating the urine, in which caſe the lateritious ſediment will be re-diſſolved, which will not happen to any ſediment of blood. Laſtly, we know no ſtate of urine without blood, which ſhews any portion of it coagulable by a heat equal to that of boiling water; but blood diffuſed in urine is ſtill coagulable in ſuch a heat; and by this teſt, therefore, the preſence of blood in urine may be commonly aſcertained. Cullen, Firſt Lines, par. 1044.

HÆMIONIUM, in *Botany*, a name by which Dioſcorides calls the *aſplenium*.

HÆMITYBION, in the *Writings of the Ancients*, a linen piece of apparel fringed on both ſides. Others call it a ſoft kind of handkerchief to wipe off ſweat; but Galen makes it ſignify a thick piece of linen cloth. In this he has an eye to ſome paſſages of Hippocrates, where the word ſeems plainly to be uſed in that ſenſe; others of the ancients have alſo uſed it exactly in the ſame meaning.

HÆMOCERCHNUS, of αιμα, *blood*, and κερχνος, *roughneſs of the throat*, in *Medicine*, a term uſed by ſome of the old writers for a ſpitting of blood, attended with a rattling noiſe in the noſe and fauces.

HÆMODIA, a ſtupor of the teeth, cauſed by auſtere and acid ſubſtances.

HÆMODORACEÆ, in *Botany*, ſo called from *Hæmodorum*, one of the genera which compoſe it; a natural order of plants eſtabliſhed by Mr. R. Brown. Prod. Nov Holl. v. 1. 299, who gives it the following characters. *Perianth* (rather *corolla*) ſuperior, rarely inferior, in ſix deep ſegments. *Stamens* inſerted into the ſame, ſix or three, in the latter caſe oppoſite to its inner ſegments; anthers in front. *Germen* with one, two, or many ſeeds in each cell; ſtyle ſimple; ſtigma undivided. *Pericarp* capſular, moſtly valvular, rarely without valves, and ſomewhat catkin-like. *Seeds* either definite and peltate, or indefinite. *Leaves* equitant.

Theſe plants differ from the *Enſatæ* of Linnæus and Gawler in having ſix ſtamens; or when there are only three, they are oppoſite to the inner ſegments of the (corolla or) calyx; the anthers moreover are placed on the fore or inſide, nor are the habits of the two orders ſimilar.—To this belongs *Dilatris*, *Lanaria*, *Wachendorſia*, and Michaux's *Heritiera*. *Xiphidium* remains doubtful, Mr. Brown having never ſeen its fruit. The New Holland genera which range under the order in queſtion are *Hæmodorum*, (ſee the next article); *Conoſtylis* and *Phlebocarya* of Brown; with *Anigozanthos* of Labillardiere.

HÆMODORUM, ſo named by the author of the preſent article, from αιμα, *blood*, and δωρον, a *gift* or *offering*, becauſe of the fine red colour of the whole herb as well as flowers. The name is given by Theophraſtus to a ſort of *Orobanche*; what preciſe ſpecies cannot be determined. Some commentators would have the word αιμοδερον, from δερας, the *ſkin*.—Smith Tr. of Linn. Soc. v. 4. 213. Vahl. Enum. v. 2. 179. Brown. Prod. Nov. Holl. v. 1. 299.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Iridibus affine*, Juſſ. *Hæmodoraceæ*, Brown.

Gen. Ch. *Cal.* none, unleſs the corolla be taken for ſuch. *Cor.* ſuperior, regular, of ſix linear, ſomewhat ſpreading, permanent, ſmooth *petals*. *Stam.* Filaments three, inſerted into the three inner petals, awl-ſhaped, much ſhorter than the corolla; anthers incumbent, ovate-oblong, obtuſe, of two cells, burſting lengthwiſe in front. *Piſt.* Germen inferior, turbinate; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma capitate. *Peric.* Capſule half-ſuperior, three-lobed, three-celled, with three heart-ſhaped valves, the partitions formed by their centres. *Seeds* two in each cell, peltate, depreſſed, thin, opaque, with a broad membranous border.

Eſſ. Ch. Petals ſix, ſuperior; the three inner ones bearing the ſtamens. Stigma capitate. Capſule half-ſuperior, of three cells. Seeds two in each cell, peltate, bordered.

A genus of New Holland, herbaceous, perennial, ſmooth plants, remarkable for their ſcarlet colour, which turns as black as ink in drying. Mr. Brown informs us the *roots* conſiſt of cluſtered ſpindle-ſhaped knobs, and even theſe are ſcarlet. The *ſtems* are ſolitary, two or three feet high, leafy; corymboſe, rarely ſpiked, in their upper part. *Leaves* ſimple, ſheathing, alternate, erect, either flat or ſomewhat cylindrical.

1. H. *coccineum*. Brown. n. 1.—Corymbs compound. Leaves flat. Three outer petals obtuſe, about half as long as the inner.—Gathered by Mr. Brown in the tropical part of New Holland. Of this we have ſeen no ſpecimen.

2. H. *planifolium*. Br. n. 2.—Corymbs compound; with ſpreading branches. Leaves flat. Inner petals rather the longeſt, bearing the ſtamens from their baſe.—Native of New South Wales, near Port Jackſon; communicated to us by ſir Joſeph Banks. The *branches* are long, and widely extended, the lateral or inferior ones riſing about the central part. *Filaments* ſlender. *Anthers* long. *Capſules* large.

3. H. *teretifolium*. Br. n. 3. (H. *corymboſum*; Vahl. Enum. v. 1. 179.)—Corymbs compound; their branches erect. Bracteas lanceolate, pointed. Leaves nearly cylindrical. Inner petals longeſt, bearing the ſtamens from their middle.

middle.—Sent by Dr. White from Port Jackſon, New South Wales, in 1792. It was alſo gathered there, as well as the laſt, by Mr. Brown. The *inflorescence* is cloſe and level-topped, exactly as in the genus *Corymbium*. *Filaments* and *anthers* ſhorter than in *H. planifolium*. This is the ſpecies from whence the generic character was originally taken, as will appear by comparing that character with the above ſpecific difference.

4. H. *laxum*. Br. n. 4.—"Corymbs compound; their branches ſpreading. Bracteas oblong, obtuſe, membranous. Leaves nearly cylindrical."—Diſcovered by Mr. Brown on the ſouthern coaſt of New Holland.

5. H. *ſpicatum*. Br. n. 5.—"Spikes elongated. Flower-ſtalks in pairs."—Found by Mr. Brown in the ſame country.

HÆMOPTYSIS, or HÆMOPTOE, in *Medicine*, from αἷμα, *blood*, and πτύω, *I ſpit*, ſignifies literally a *ſpitting of blood*.

It is not every diſcharge of blood by the mouth, however, to which the term is applied; for, in that caſe, the ſame appellation would denote ſeveral forms of diſeaſe, altogether diſtinct in their nature and origin, and equally different in the danger attendant on them, and in the method of treament requiſite for their cure. Blood eſcaping from the veſſels of the poſterior part of the noſe, of the gums, throat, gullet, and ſtomach, muſt of courſe be diſcharged by the mouth, as well as that which eſcapes from the veſſels of the lungs; but it is to this laſt ſpecies of hæmorrhage only that the term *hæmoptyſis* is appropriated; which is therefore ſynonymous with hæmorrhage from the lungs, or pulmonary hæmorrhage.

The careful diſtinction of this hæmorrhage, from thoſe juſt mentioned, is of conſiderable practical importance: becauſe, while the latter are generally neither the cauſe nor the effect of any dangerous condition of the body, hæmoptyſis is always an alarming affection; being moſt commonly either the precurſor of that moſt fatal malady, pulmonary conſumption, or one of the ſigns indicative of the commencement or actual preſence of the diſeaſe. Dr. Cullen, indeed, conſidered hæmoptyſis as the ordinary exciting cauſe of conſumption of the lungs; and, therefore, has violated the order of his noſological ſyſtem, by placing conſumption among the "Hæmorrhagiæ." (Claſs I. Ord. 4.) But, as we have already ſtated, there are many reaſons for believing, that hæmoptyſis is often not the cauſe, but one of the ſymptoms of the diſeaſe. See CONSUMPTION.

When we reflect upon the ſtructure of the lungs, and the nature of the circulation through them, the frequency of the diſeaſe will be far from occaſioning any ſurpriſe. The blood-veſſels of the lungs are more numerous than thoſe of any other part of the body of the ſame bulk; indeed thoſe organs conſiſt almoſt entirely of blood-veſſels, the largeſt of which, as they ariſe from the heart, are more immediately, than in any other part, ſubdivided into veſſels of the ſmalleſt ſize; and theſe ſmall veſſels, ſpread out near the internal ſurfaces of the bronchial cavities, are ſituated in a looſe cellular texture, and covered by a tender membrane only. And when we conſider farther, the conſtant alternate compreſſion and dilatation of the whole collection of minute veſſels in reſpiration, and the frequency and readineſs with which they are gorged with blood, as by active exerciſe, ſevere coughing, ſneezing, &c. we may underſtand why a hæmorrhage from the lungs is one of the moſt frequent that occurs, and why any violent ſhock, given to the whole body, ſo readily produces it.

The ancients obſerved, that there are three ways in which blood might eſcape from the veſſels of the lungs, and give riſe to hæmoptyſis: namely, 1. By a mechanical rupture of the veſſels from external violence, which, according to Aretæus and Galen, was called ῥῆξις, or *rupture:* 2. By a corroſion of the veſſels from an acrimony of the fluids, which was termed διάβρωσις, *eroſion;* and, 3. By a mere dilatation of the extreme apertures of the veſſels, which they called ἀναστόμωσις, *anaſtomoſis*, or *opening of mouths*. (See Aretæus, de cauſ. et ſignis morbor. acut. lib. ii. cap. 2. Galen de uſu partium, lib. vii. cap. 3.) This diviſion of the modifications of hæmoptyſis was partly the reſult of obſervation, and partly of hypotheſis; as may be collected from the diagnoſtics and prognoſtics which they deduced from it. Thus an hæmoptyſis ariſing from the firſt of theſe cauſes may be recognized, they affirm, if a perſon ſpits blood immediately after a fall, or blow, lifting a great weight, &c.; in which caſe a ſudden *rupture* of the veſſels muſt be inferred. If one of the larger veſſels be thus ruptured, death may ſpeedily enſue, from the quantity of blood diſcharged; but if the hæmorrhage be moderate, this ſpecies of it may be conſidered as not without a conſiderable chance of a cure. But, 2dly. If the hæmoptyſis occur from eroſion of the veſſels, the cure will be much more difficult; for "in this caſe," Aretæus obſerves, "an ulcer is produced, not a wound." Hæmoptyſis may be known, it is added, to proceed from this cauſe, "if no external force has been applied; if a long irritating cough has preceded; if ſome pain has been felt in the inſide of the thorax; if the blood be ſpit out in ſmall quantities, but almoſt continually, or, at leaſt, if it often returns." Now, the practical inference from theſe obſervations is ſound; but the exiſtence of a corroſive acrimony in the blood is purely hypothetical. Theſe preceding and concomitant ſymptoms juſtly intimate the danger of the hæmoptyſis; becauſe they imply a conſiderable progreſs of diſeaſe in the lungs towards a confirmed conſumption, of which the hæmoptyſis is at once a ſign and a conſequence. But, 3dly, a ſpitting of blood from *anaſtomoſis*, or dilatation of the mouths of the veſſels, was deemed far leſs dangerous; becauſe the veſſels, although dilated, were entire, and would contract again, it was believed, by their own elaſticity; and the fluids were at the ſame time healthy. This ſpecies of hæmoptyſis was ſaid by Aretæus to occur in women during a ſuppreſſion of the catamenia, of which it was vicarious: and Galen remarks, that it was altogether free from pain in the part affected, which occurred in the other two ſpecies. In this caſe again, although the inference of the comparative ſafety of a vicarious hæmoptyſis is in ſome degree correct, yet the ſuppoſition of the blood being diſcharged ſimply from the dilated mouths of the exhalent arteries, without any rupture of veſſels, is altogether gratuitous.

A more correct and uſeful view of the varieties of hæmoptyſis may be obtained if we lay aſide hypotheſis, and conſider the various conditions of the body in which theſe modifications appear, as well as the morbid ſtate of the lungs, which diſſection diſcovers to us in conſumptive diſeaſes, and which the ancients had not the opportunities of inveſtigating.

There are ſeveral obvious peculiarities of conſtitution, which appear to prediſpoſe the individual poſſeſſing them to the occurrence of hæmoptyſis. A general delicacy of habit, which is marked by a ſlender make, a delicate ſkin, fine complexion, a flaccidity and ſoftneſs of the muſcular parts, a long neck, and narrow cheſt, in which the veſſels of the lungs are equally delicate with thoſe of the other parts of the body, may be conſidered as conſtituting a particular prediſpoſition to hæmoptyſis. In ſuch a habit there is generally alſo a great degree of ſenſibility and irritability.

irritability, and therefore ſome acuteneſs of the mental faculties and cheerfulneſs of diſpoſition. This form and conſtitution are frequently hereditary. In addition to the general delicacy of ſuch a habit, it frequently has ſomewhat of a ſcrofulous taint, that is, any ſolution of parts, which it ſuffers, inſtead of readily healing by the adheſive inflammation, is liable to go on to an unfavourable ſuppuration. The narrowneſs of the cheſt, as Dr. Cullen obſerves, implies a ſmaller capacity of the lungs than in more hardy habits; whence there muſt be a faulty proportion between the capacity of the veſſels of tht lungs, and that of the veſſels of the reſt of the body, and conſequently a tendency to an habitual plethora of the lungs. Whenever, therefore, the balance of the circulation between the ſyſtems of the pulmonary artery and of the aorta is diſturbed, the danger of hæmoptyſis muſt occur.

Such being the condition of the body, it will appear, that a ſpitting of blood may be occaſioned from the mere circumſtance of the prediſpoſition, or prediſponent cauſe, ariſing to a conſiderable height; when, under the ordinary actions of life, the circulation is even ſlightly diſturbed. But in thoſe who are prediſpoſed to it, hæmoptyſis is readily brought on by various exciting cauſes. Thus expoſure to great external heat, as in manufacturers employed in furnaces, glaſs-houſes, &c.; all violent ſtrainings of the muſcles, ſuch as attempts to lift or carry burdens of great weight; blowing violently, as in playing on trumpets, or other wind inſtruments; great exertions, by which the circulation is hurried, as in wreſtling, running, jumping, aſcending declivities, and the like; in which the extreme congeſtion of the blood in the veſſels of the lungs is evinced by the ſhort and laborious breathing, the ſenſe of ſuffocation or of ſtuffing in the breaſt, and the violent efforts of the heart to overcome the reſiſtance. To the laborious exertion in climbing mountains, therefore, rather than to the rarity of the air, we ſhould be diſpoſed to aſcribe the occurrence of hæmoptyſis under ſuch circumſtances. Among other cauſes, which diſturb the balance of circulation, and occaſion a congeſtion of blood in the lungs, and hæmoptyſis in thoſe who are prediſpoſed to it, we may add exceſſive drinking of intoxicating liquors; violent emotions of the mind, eſpecially anger; and laſtly, all great and ſudden agitations of the cheſt, as by coughing, ſhouting, ſneezing, and the like.

It is to be obſerved, however, that this prediſpoſition of conſtitution, and this delicacy and diſproportion in the formation of the lungs, are frequently conjoined with actual diſeaſe in theſe organs, previous to the occurrence of hæmoptyſis. Diſſection has ſhewn, that, in individuals of the phthiſical temperament, the formation of tubercles had gone on to a conſiderable extent in the lungs, before the bleeding had taken place. Theſe little bodies, which are generally conſidered as of a ſcrofulous nature, contribute to diminiſh the already too contracted capacity of the cheſt, and to impede the free circulation; they are alſo liable to inflame from expoſure to cold; and their ordinary progreſs is to a ſlow and bad ſuppuration, forming ulcers of various extent. Thus the rupture of the minute veſſels is greatly endangered by the obſtruction of the circulation, by the partial inflammations, and is directly cauſed by the deſtruction of thoſe minute veſſels by the proceſs of ulceration. Theſe laſt modifications of hæmoptyſis are apparently thoſe included by the ancients under the hæmoptyſis by *diabroſis*; and the correctneſs of their unfavourable prognoſis, as well as of their diagnoſis, in ſuch caſes is thus ſatisfactorily explained. The ſpontaneous occurrence of the hæmorrhage, or at leaſt the "abſence of any external force," together with the "previous exiſtence of an irritating cough, and pain in the ſide," reſult from the actual previous diſeaſe of the lungs; and the greater danger of this ſpecies of hæmoptyſis neceſſarily follows from the tendency of this previous diſeaſe to go on to a bad ſuppuration, that is, to pulmonary conſumption.

This view of the ſubject likewiſe ſerves to explain why the hæmorrhage from the lungs in the two other ways above-mentioned, namely, from mechanical rupture by external violence, and as vicarious of ſuppreſſed diſcharges, (ſuch as the catamenia, the piles, &c.) is much leſs dangerous than that from *diabroſis*. For, as they do not imply any previous malformation or phthiſical habit, the veſſels may heal, as in other caſes of hæmorrhage, as from the noſe, bowels, &c. and the healthy circulation be reſtored. And ſuch, in fact, is frequently the event. Nevertheleſs, there is always ſome degree of danger from a rupture of the veſſels of the lungs, however occaſioned. For the conſtant motion of the part, its unceaſing expoſure to the air inhaled in reſpiration, and the extreme delicacy and ſlight ſupport of the minute veſſels in the lungs, render the healing of thoſe veſſels more difficult than in other parts of the body; ſo that, where there is not very conſiderable vigour of conſtitution, or where the leaſt prediſpoſition to the diſeaſe exiſts, ſuch accidental injury to the veſſels may lay the foundation of conſumption, which under other circumſtances would not have occurred.

In whatever manner hæmoptyſis is occaſioned, it moſt commonly comes on with a ſenſe of weight and anxiety in the cheſt, ſome uneaſineſs in breathing, ſome pain of the breaſt or other parts of the thorax, and ſome ſenſe of heat under the ſternum or breaſt-bone; and very often, before the diſeaſe appears, a ſaltiſh taſte is perceived in the mouth. Immediately before the diſcharge of blood a degree of irritation is felt at the top of the larynx, to relieve which a hawking is made, which brings up a little blood, of a florid colour, and ſomewhat frothy. The irritation returns; and in the ſame manner more blood of a like kind is brought up, with ſome noiſe in the windpipe, as of air paſſing through a fluid. The blood iſſuing is ſometimes at firſt in very ſmall quantity, and ſoon diſappears altogether; but in other caſes, eſpecially when it repeatedly occurs, it is in greater quantity, and frequently continues to appear for ſeveral days together. It is ſometimes profuſe, but rarely in ſuch quantity as, either by its exceſs, or by its ſudden ſuffocation, to prove immediately mortal. It commonly either ceaſes ſpontaneouſly, or is ſtopped by the remedy employed.

With regard to the *diagnoſis*, it is very neceſſary, as we have already remarked, to diſtinguiſh the different parts from which blood, thrown out by the mouth, proceeds; whether from the internal ſurface of the mouth itſelf, from the fauces, or the adjoining cavities of the noſe, from the ſtomach, or from the lungs. In moſt inſtances this diſtinction may be made by attending to the following circumſtances.

When blood ſpit out proceeds from ſome part of the internal ſurface of the mouth itſelf, it comes out without any hawking or coughing; and generally, upon inſpection, the particular ſource of it becomes evident. When it proceeds from the throat or adjoining cavities of the noſe, it may be brought out by hawking, and ſometimes by coughing; ſo that, in this way, a doubt may ariſe concerning its real ſource. A patient often lays hold of theſe circumſtances to pleaſe himſelf with the opinion, that it comes from the fauces, and he may be allowed to do ſo; but a phyſician cannot readily be deceived, if he conſider, that a bleeding from the fauces is more rare than one from the lungs; that the former ſeldom happens but to perſons who have been be-

fore liable either to an hæmorrhagy of the noſe, or to ſome evident cauſe of eroſion; and in moſt caſes, by looking into the fauces, the diſtillation of the blood, if it come from thence, will be perceived.

When vomiting accompanies the diſcharge of blood by the mouth, ſince vomiting and coughing often mutually excite each other, ſo they may be frequently joined, and render it doubtful, whether the blood thrown out proceeds from the lungs or from the ſtomach. We may generally decide, however, by conſidering, that blood does not ſo frequently proceed from the ſtomach as from the lungs; that blood proceeding from the ſtomach commonly appears in greater quantity, than when it proceeds from the lungs; that when it is diſcharged from the lungs, it is uſually of a florid colour and mixed with a little frothy mucus only; whereas, when it proceeds from the ſtomach, it is commonly of a darker colour, more grumous, and mixed with the other contents of that organ; and that the coughing or vomiting, according as the one or the other *firſt* ariſes, in the caſes in which they are afterwards joined, may ſometimes point out the ſource of the blood. Not to mention that the vomiting of blood happens moſt frequently to females. (See Hæmatemesis.) But when to all theſe conſiderations we add the obſervation of other circumſtances, which may concur to point out the lungs as the ſeat of the diſeaſe, the preſence of hæmoptyſis may commonly be ſufficiently aſcertained: theſe are the periods of life, between puberty and thirty-five; the form and habit of body, and other marks of a prediſpoſition, already ſtated; the actual previous exiſtence of cough, pain of the ſide, and other ſymptoms of diſorder in the cheſt; and more eſpecially if, together with theſe, ſome of the exciting cauſes have immediately before been applied. (Cullen.)

Of the Cure of Hæmoptyſis.—As the hæmoptyſis, which occurs in thoſe who are prediſpoſed to the diſeaſe, is always accompanied by what has been termed a phlogiſtic diatheſis, or a certain degree of febrile action in the arterial ſyſtem, the principal indications of cure will be, firſt, to remove this diatheſis, and every ſpecies of irritation, which may contribute to keep it up; after which we muſt endeavour to allay pain, and to procure an agreeable diſtribution of blood throughout the vaſcular ſyſtem, and thus to take off too great a determination of blood to particular parts. At the ſame time we muſt be careful to avoid or to remove ſuch occaſional cauſes, as may ſtill continue to operate.

It will be generally neceſſary, therefore, to purſue the antiphlogiſtic regimen, with more or leſs rigour, according to the ſtrength of the patient. When the temperament is ſanguine, and the ſtrength not impaired, it is ſometimes adviſable to reſort to blood-letting, in order ſpeedily to reduce the general inflammatory ſtate of the ſyſtem. This evacuation was formerly carried to a great extent, in conſequence of the appearance of the inflammatory cruſt, or buffy coat, upon the blood drawn: but farther experience has ſhewn that this buffy coat continues to appear on the blood, even to the laſt ſtage of conſumption, and, therefore, is no proper practical guide to the uſe of the lancet. Hence, although ſmall bleedings afford a temporary relief, yet, as they contribute to reduce the declining ſtrength of the patient, they are not generally reſorted to in the delicate habits, that are moſt frequently the ſubjects of hæmoptyſis. This inflammatory diatheſis may be more ſafely combatted by gentle laxatives, eſpecially of the ſaline claſs; and by regulating the temperature of the apartment of the patient, ſo as to avoid the influence of external heat, by retaining a regular and moderate coolneſs, and alſo by avoiding the uſe of too much cloathing. Yet the irregular tranſition from heat to cold, or the contrary, by paſſing from a warm houſe to the cold and moiſture of a wintry or vernal atmoſphere, and *vice verſâ*, is ſtill more pernicious, and ought to be ſcrupulouſly ſhunned.

The ſame object will be aided by the medicines, which are called refrigerants and ſedatives, or ſuch as allay the exceſſive irritability of the heart and arteries. Hence the uſe of the vegetable and mineral acids is frequently reſorted to; and the neutral ſalts, eſpecially nitre, have been conſiderably extolled for their virtues in the cure of hæmoptyſis. Dr. Dickſon affirms, that, when nitre was given early in hæmoptyſis, he could almoſt equally depend upon it, as upon the Peruvian bark for the cure of an intermittent fever. (See Med. Obſ and Inquir. vol. iv. p. 209.) The elixir of vitriol, as it was formerly called, or the diluted ſulphuric acid, has alſo been an eſteemed remedy for ſpitting of blood; and it is ſtill commonly preſcribed, and often with advantage, under the form of the infuſion of roſes (of the pharmacopœias). It muſt be obſerved, however, that hæmoptyſis is very liable to ceaſe ſpontaneouſly after a ſhort time, ſometimes to appear no more during the progreſs of the conſumption, which too often follows it, but often to return for a certain period, and ceaſe again: whence, it is eaſy for any medicine, which happens to be adminiſtered at the time, to gain the credit of the cure; and our concluſions, reſpecting the efficacy of any medicine in the diſeaſe, ought, therefore, to be drawn with much caution.

The digitalis, or fox-glove, wich appears to be poſſeſſed of powerful ſedative properties upon the action of the vaſcular ſyſtem, has frequently, in the ſame manner, been followed by the ſpeedy ceſſation of hæmoptyſis, and is, doubtleſs, an uſeful auxiliary in repreſſing the diſeaſe. Ceruſſa acetata has alſo been employed for the ſame purpoſe, eſpecially by the continental phyſicians, and by ſome of them much extolled: but the deleterious conſequences which are known to reſult from the poiſon of lead, however introduced into the ſyſtem, have rendered Engliſh practitioners, in general, averſe to the employment of this medicine.

With a view to relieve pain, and procure an equable diſtribution of blood, the uſe of ſmall doſes of opium, (which, however, is prejudicial in very acute forms of the diſeaſe), hyoſcyamus, and conium, (formerly called cicuta,) is to be reſorted to, as well as that of gently relaxing diaphoretics. And although nothing is more neceſſary in hæmoptyſis than avoiding bodily exerciſe; yet ſome kinds of geſtation, ſuch as ſailing, ſwinging, and travelling in an eaſy carriage, on ſmooth roads, have often proved a remedy; probably by determining the flow of blood from the lungs to the ſurface and extremities. Bliſters applied to the breaſt, or back, are ſometimes beneficial.

Both during the preſence of hæmoptyſis, and after its ceſſation, the diet ſhould be exceedingly light, and free from any ſtimulant properties. Spirituous and fermented liquors ſhould be totally refrained from, as well as ſolid animal food: the various preparations of milk, vegetables, the farinaceæ, and fruits, ſhould conſtitute the chief or ſole aliment of the patient. This plan is not leſs uſeful with a view to prevent a return, than to aid in the removal of the diſeaſe, when preſent.

We have ſaid nothing reſpecting the exhibition of cinchona and chalybeate medicines, which were formerly recommended, as experience ſeems to have proved them prejudicial to this diſeaſe. See Cullen, Firſt Lines, par. 830, et ſeq. Van Swieten. Aph. 1198, et ſeq.

Hæmorrhæa Petechialis, a diſeaſe which has received a variety of denominations, and appears to be a modification of the ſcurvy (ſcorbutus) ſtrictly ſo called.

This diſeaſe reſembles the ſea-ſcurvy in its leading ſymptoms,

ſymptoms, being chiefly characterized by the appearance of *petechiæ* and *vibices*, or purple ſpots, and livid effuſions, as from the ſtrokes of a whip, or bruiſes, unconnected with fever, and accompanied, in ſome caſes, with the diſcharge of conſiderable quantities of blood from various parts of the body. At the ſame time it differs from the ſcurvy, in the non-appearance of ſponginеſs in the gums, of fœtid ulcers on the extremities, &c. in originating independently of ſalted proviſions, and in not being curable by citric acid and freſh vegetables, and in the general courſe of the diſeaſe.

It has been denominated "land-ſcurvy;" "petechiæ ſine febre," (by Dr. Graaf, Göttingen, 1775,) a term moſt generally adopted; "Purpura," and "Purpura ſine febre," (by Cuſſon,) "Phœnigmus petechialis," (by Sauvages,) and "Aimorrhœa," (by Dr. Duncan). The appellation of hæmorhæa petechialis was given to it by Dr. Adair, in his inaugural diſſertation, Edin. 1789, and, as it deſignates the diſeaſe by its two leading ſymptoms, the paſſive hæmorrhage, and the petechiæ, it appears to be the moſt appropriate term. But as Dr. Willan's nomenclature of cutaneous diſeaſes, in which the old appellation of "Purpura" is retained, is likely to be generally adopted in the profeſſion, we ſhall defer the deſcription of this ſingular diſeaſe to that head.

HÆMORRHAGIA, or HÆMORRHAGE. See HEMORRHAGE.

HÆMORRHOIDS. See HEMORRHOIDS.

HÆMORRHOSCOPIA, formed of αιμα, *blood*, ῥεω, *I flow*, σκοπεω, *I obſerve*, an old term, uſed by the writers in *Medicine*, to expreſs an examination of the blood drawn from a patient by phlebotomy, in order to judge of the nature of a diſeaſe by it.

HÆMORRHUS, in *Zoology*. See *Blood* SNAKE.

HÆMOSTASIA, formed of αιμα and στασις, *ſtation*, or *reſt*, occurs in ſome writers as the name of a diſeaſe occaſioning ſudden death; and it is ſaid to be a total ſtagnation of the whole maſs of blood from a plethora.

HÆMOSTATICA, formed of αιμα and ιστημι, *I ſtop*, a name given by ſome authors to medicines uſed to ſtop hæmorrhages, whether internally taken, or externally applied.

HÆMUS, in *Geography*, a mountain, rather a chain of mountains, of European Turkey, that ſeparates Servia from Macedonia. This chain has been much celebrated by the ancients, on account of its great elevation, as well as extent, as they infer from the numerous and large rivers which iſſue from its ſides. But Dr. Brown, who has viſited parts of this mountain, and who informs us that it is ſuppoſed to extend from the Euxine to the Adriatic, concludes that the elevation cannot be conſiderable, becauſe no ſummit of it is covered with perpetual ſnow. The middle parts of this chain were by the ancients called Scomius and Orbalus, while the Scardus may be conſidered as its furtheſt branch on the weſt. If with M. D'Anville we place the "Hæmi extremia," the fartheſt eaſtern point of the Hæmus at Emineh, and extend it thence above Filipopoli and Sofia to the S. of Servia, we ſhall find an extent of more than 400 miles, now known under various names, as Emineh, or Heminch Dag, perhaps a remnant of the ancient appellation, on the E.; Bulkau and Samoco in the middle; Joan W.; while the Deſpoto Dag branches off to the S.E.; and may, perhaps, be the Rhodopé of the ancients. From the weſtern branch of the Hæmus ſeem to branch off two other extenſive chains; one running N.W. between Dalmatia on the W., and Boſnia and Servia on the E.; while the other paſſing S. forms the mountains of Albania, and the W. of Greece. The northern chain begins with the Scardus of the ancients, continued by the Buſſinius and the Albius. Pinkerton.

HAEN, ANTHONY DE, in *Biography*, profeſſor of the practice of medicine in the univerſity of Vienna, was born at Leyden in 1704, and was one of the diſtinguiſhed pupils of the celebrated Boerhaave. After having received the degree of M. D. at his native place, he ſettled at the Hague, where he practiſed with conſiderable reputation and ſucceſs for nearly twenty years. Baron Van Swieten, however, being acquainted with the extent of his talents, invited him to remove to Vienna, with the view of uniting with him in the propoſed plan of reform, which he had prevailed on the empreſs to ſupport, in the medical faculty of that capital. De Haen accordingly repaired to that city in 1754; and his merits were found fully equal to the expectations that had been formed of them. At the expreſs command of Maria Thereſa, he undertook a ſyſtem of clinical education, in the hoſpital which he ſuperintended, as the moſt advantageous method of forming good phyſicians: the reſult of this duty was the collection of a great number of valuable obſervations, which were publiſhed in the ſucceſſive volumes of the work, entitled "Ratio Medendi in Noſocomio Practico," Vienna, 1757, which amounted ultimately to ſixteen. He died in the year 1776, at the age of ſeventy-two.

He left ſeveral other works, of which the following are the titles: "Hiſtoria Anatomico-Medica morbi incurabilis Medicos paſſim fallentis," Hague, 1744. "De Colica Pictonum Diſſertatio," ibidem, 1745. "De Deglutitione impeditâ." ibid. 1750. "Quæſtiones ſuper Methodo inoculandi Variolas," Vienna, 1757. "Theſes pathologicæ de Hæmorrhoidibus," ibid. 1759. "Refutation de l'Inoculation ſervant de reponſe à M. M. De la Condamine et Tiſſot," Vienna, 1759. "Theſes ſiſtentes febrium diviſiones," ibid. 1760. "Difficultates circa modernorum ſyſtema de ſenſibilitate et irritabilitate corporis humani," 1761. "Vindiciæ difficultatum circa, &c." ibid 1762. "Lettre à un de ſes amis au ſujet de la Lettre de M. Tiſſot à M. Hirzel," 1758. "Reſponſio ad apologeticam Epiſtolam Balthaſaris-Ludovici Tralles, circa Variolarum Inoculationem, &c." ibid. 1764. "Epiſtola de Cicutâ, &c." ibid. 1765.

Gruner, in his Medical Almanac for 1782, ſays, "Van Haen was a man of great learning and practical knowledge, but an enemy to all new opinions, which he violently oppoſed; as appears from his diſpute with Haller on irritability and ſenſibility; with Tralles on inoculation; and with baron Von Storck, on the uſe of poiſonous plants in medicine; and from his obſervations on the nature and origin of malignant fevers, on the plague, &c.; in which, however, ſetting aſide the polemic part, the reader will find a great deal of uſeful information." See Eloy. Dict. Hiſt. Gen. Biog.

HÆPHESTITES LAPIS, in *Natural Hiſtory*, a name given by authors to a ſtone of a reddiſh colour, and capable of a high poliſh. The ancients gave it this name, from its property of ſetting fire to dry ſubſtances by reflection, when formed into a concave ſpeculum. They hence called it the *Vulcanean-ſtone*, or *fire-ſtone*, not conſidering that the ſhape into which they formed it, and not the nature of the ſtone, was the cauſe of the effect; any ſtone being capable of the ſame, if hard enough to bear a proper poliſh. About Hildersheim they have, at this time, a ſort of blackiſh-red coarſe jaſper, which they take to be the hæphæſtites of the ancients, and uſe it, at this day, for the ſame purpoſes, hollowing large pieces of it into ſpeculums, and ſetting them, when well

well polished, in proper frames, and using them as burning-glasses.

HÆNEL, JACOB, HÆNDL, or GALLUS, in *Biography*, mentioned by Walther under all these names, was chapel-master to the bishop of Olmutz, and a publisher of four books of spiritual cantatas or motets, at Prague, in four, five, and six parts; in the last set of which, a motet of his composition, in twenty-four parts, for four choirs, gained him great reputation among the admirers of polyphonic composition.

He was a native of Crain, in Germany, and flourished about the middle of the sixteenth century.

HÆREDE ABDUCTO, in *Law*, is a writ which anciently lay for the lord, who, having by right the wardship of his tenant under age, could not obtain his body, as being conveyed away by another.

HÆREDE *deliberando alii qui habet custodiam terræ*, a writ directed to the sheriff, willing him to command one that had the body of him who was ward to another, to deliver him to the person whose ward he was on account of his land. See WARD.

HÆREDE *Rapto*. See FORCIBLE *Abduction*, and RAVISHMENT *de Gard*.

HÆREDIPETA, in our *Ancient Law Books*, the next heir. See HEIR.

"Et mellus hæredipeta suo propinquo vel extraneo periculosa sane custodia committatur." Leg. Hen. I. cap. 70.

HÆREDITAS JACENS. See ABEYANCE and OCCUPANCY.

HÆRESIARCH, HÆRESIARCHA, of the Greek, αἱρεσιαρχης, an arch-heretic. See HERETIC.

HÆRESIS, the separation of a diseased from a sound part.

HÆRESIS, *Heresy*. See HERESY.

HÆRETICO COMBURENDO, in *Law*, a writ which anciently lay against an heretic, who having once been convicted of heresy by his bishop, and having abjured it, afterwards falling into it again, or into some other, is thereupon committed to the secular power. This writ is thought by some to be as ancient as the common law itself; however, the conviction of heresy by the common law was not in any petty ecclesiastical court, but before the archbishop himself in a provincial synod, and the delinquent was delivered over to the king, to do with him as he pleased: so that the crown had a controul over the spiritual power, and might pardon the convict by issuing no process against him; the writ being not of course, but issuing by the special direction of the king in council. (1 Hal. P. C. 395.) But by 2 Hen IV. cap. 15. the diocesan alone, without the intervention of a synod, might convict of heretical tenets: and unless the convict abjured his opinions, or if after abjuration he relapsed, the sheriff was bound *ex officio*, if required by the bishop, to commit the unhappy victim to the flames, without waiting for the consent of the crown. This writ remained in force, and was actually executed on two Anabaptists in the seventeenth of Elizabeth, and on two Arians in the ninth of James I.

Sir Edward Coke was of opinion, that this writ did not lie in his time; but it is now formally taken away by statute 29 Car. II. cap. 9. But this statute does not extend to take away or abridge the jurisdiction of Protestant archbishops or bishops, or any other judges of any ecclesiastical courts, in cases of atheism, blasphemy, heresy, or schism, and other damnable doctrines and opinions; but they may prove and punish the same according to his majesty's ecclesiastical laws, by excommunication, deprivation, degradation, and other ecclesiastical censures, not extending to death, in such sort and no other, as they might have done before the making of this act. (Sec. 2.) See HERESY.

HÆRETICUS, HERETIC. See HERETIC.

HÆRINGHE, in *Geography*, a town of France, in the department of the Lys, and chief place of a canton, in the district of Furnes. The place contains 1309, and the canton 13,931 inhabitants, on a territory of 167½ kiliometres, in 13 communes.

HÆRLEBECKE, a town of France, in the department of the Lys, and chief place of a canton, in the district of Courtray. The place contains 2990, and the canton 14,457 inhabitants, on a territory of 85 kiliometres, in 5 communes.

HAERLEM, or HAARLEM, a large, handsome, rich, and populous city of Holland, the capital of a country called "Kemmer," situated about a league from the sea, on the river Sparen. It is fortified, like Leyden, by old brick walls; and contains, besides the church, which was once the cathedral, and which is reckoned the largest in the province of Holland, four Dutch churches, one French, one Lutheran, one Arminian, four Anabaptist, and also private houses or chapels for the Roman Catholics. In the great church are preserved the models of three ships, in which some crusaders from Haerlem sailed to Damietta in 1249, and in the steeple are two bells brought from that place. Its celebrated organ is more remarkable for power than sweetness. The stadt-house is a grand building, situated at one end of the market-place; it contains many valuable pictures, and, among others, the first painting in oil by Eyck in 1437. sold, during the siege in 1572, for a few stivers, and now valued at 2000*l*. The magistracy is composed of an escaut or bailiff, a pensionary, two burgomasters, seven echevins, and 22 common-councilmen. The number of inhabitants is reckoned at about 40,000. Haerlem carries on considerable manufactures in linen, ribbands, and tapes, and exports a great quantity of beer to Friesland, and other places. Here is also a great trade for flowers. The house of Laurence Coster, to whom the Dutch ascribe the invention of the art of printing, is situated near the great church; but their boast has been superseded in favour of Mentz; 10 miles W. of Amsterdam. N. lat. 52° 22'. E. long. 4° 37'.

This city is rendered interesting to lovers of music by the fame of its organ in the great church.

In order to hear and examine which, we, thirty years ago, expressly visited that city. Expectation, however, when raised very high, is not only apt to surpass probability, but possibility. Whether imaginary excellence diminished the real, on this occasion, we know not, but we were somewhat disappointed upon hearing this instrument. In the first place, the person who plays it is not so great a performer as he imagines; and in the next, though the number of stops amounts to sixty, the variety they afford is by no means equal to what might be expected. As to the *vox humana*, which is so celebrated, it does not at all resemble a human voice, though a very good stop of the kind: but the world is very apt to be imposed upon by names; the instant a common hearer is told that an organist is playing upon a stop which resembles the human voice, he supposes it to be very fine, and never enquires into the propriety of the name, or exactness of the imitation. However, with respect to our own feelings, we must confess that of all the stops which we have yet heard, that have been honoured with the appellation of

vox humana, no one in the treble part has ever reminded us of any thing human, ſo much as of the cracked voice of an old woman of ninety, or, in the lower parts, of Punch ſinging through a comb.

As this organ is not only ſaid to be the largeſt, but the beſt in Europe, that is, in the world, we ſhall in the article ORGAN give a liſt of the ſtops which it contains, with equivalent Engliſh names, to ſuch as are uſed in our country, and ſhort explanations of the reſt.

This inſtrument has ſixty ſtops, two tremulants, two couplings, or ſprings of communication, four ſeparations or valves to cloſe the wind-cheſt of a whole ſet of keys, in caſe of a *cipher*, and twelve pair of bellows.

Upon the whole, it is a ſtupendous ſtructure, though we think that given to the new church at Hamburgh is larger, and that of the old kirk, in Amſterdam, better toned; but all theſe enormous machines ſeem loaded with uſeleſs ſtops, or ſuch as only contribute to augment noiſe, and to ſtiffen the touch.

HAERLEM *Iſlands*, a cluſter of ſmall iſlands in a bay on the N. ſide of New Guinea. S. lat. 3° 42'. E. long. 13° 6'.

HAERLEM *Meer*, a large lake of Holland, between Amſterdam, Leyden, and Haerlem, navigable for boats

HÆRUCA, in *Zoology*, a genus of inteſtinal worms eſtabliſhed by Goëze, and which, according to that writer, has the body round, the anterior part two-necked, and ſurrounded by a row of prickles; and no proboſcis.

This genus is cloſely allied to that called by helmintholoGiſts *echinorynchus*, the principal difference conſiſting in the latter-mentioned tribe being furniſhed with a retractile proboſcis, while the hæruca is entirely deſtitute of that organ. It may be proper to obſerve that, notwithſtanding this obvious diſſimilarity, and the credit uſually aſcribed to the accuracy of Goëze, ſome continental writers reject his genus hæruca, and refer the ſpecies he deſcribes to the analogous genus *echinorynchus*; Gmelin nevertheleſs adopts it, the genus being inſerted in the laſt edition of the Linnæan Syſtema Naturæ. The ſpecies called by Goëze murio, was diſcovered by that naturaliſt in the inteſtines of the mouſe; the body is greyiſh-white, and wrinkled.

HAFAIVA, in *Geography*, one of the Friendly iſlands, about 6 leagues N.N.E. of Annamooka.

HAFAR, a town of Perſia, in the province of Chuſiſtan; 36 leagues S. of Suſa.

HAFDAEL, a town of Norway, in the dioceſe of Drontheim; 55 miles N.E. of Runſdal.

HAFFENREFFER, SAMUEL, in *Biography*, a phyſician, was born in the duchy of Wirtemberg, and practiſed his profeſſion firſt at Kircheim, in Suabia, and afterwards at Tubingen, where he became a profeſſor, and taught with conſiderable reputation. He died in 1660, at the age of 73. He left ſeveral works, to moſt of which he gave the quaint titles peculiar to the times and the country in which he lived. Theſe are "Raphaël Artem Medicam feliciter cùm inchoandi, tum continuandi, &c.," Tubingen 1622, 12mo. reprinted at Francfort and Ulm. "Pandocheion æolodermon, ſive Noſodochium cutis, &c." ibid. 1630, 8vo.—"Vexillum Raphäeliticum, &c." ibid. 1631. "Monochordon ſymbolico-biomanticum, abſtruſiſſimam Pulſuum doctrinam ex harmoniis muſicis dilucidè, figuriſque ocularitèr demonſtrans, &c." Ulm, 1640, 8vo.—"Officina iatrica, continens pharmaca ſelecta, Hippocratico-Galenica et Hermetico-Paracelſica, &c." ibid. 1653, 8vo.—Eloy Dict. Hiſt.

HAFFHERT, in *Ornithology*, the name of a bird deſcribed by Hoier, which is ſeen uſually at ſea, and is ſuppoſed to be a foreteller of ſtorms. See PROCELLARIA *Glacialis*.

HAFIZI, or HAFIZLER, is a name given in Turkey to thoſe who learn the whole Alcoran by heart; and who, on this account, are held in great veneration by the people.

HAFLE, in *Ichthyology*, one of the names of the dolphin of the Portugueſe, and coryphæna hippurus of Linnæus.

HAFNER, in *Biography*, a muſical publiſher of Nuremberg, in Germany, who engraved muſic on copper during the laſt century, in a more neat manner than moſt other publiſhers in Europe. Many of the earlieſt and beſt works of Emanuel Bach have been delivered to the public from the ſhop of Hafner.

HAG, in *Rural Economy*, a term provincially applied to a coppice, or originally, perhaps, ſuch wood as was ſet apart for the purpoſe of fuel.

HAG-*Fiſh*, in *Ichthyology*. See GASTROBRANCHUS.

HAGA, in our *Old Writers*, has different ſignifications. In Doomſday it is taken for a houſe in a city or borough. An ancient anonymous author ſays it is a houſe with a ſhop, *Domus cum ſhopa*.

HAGABLUM, the ſame with *gablum* or *gabel*.

HAGÆA, in *Botany*, in honour of M. Lahaye, a botanical gardener, who went out with the expedition in ſearch of De la Pérouſe, and found this plant on the Peak of Teneriffe. Lamarck had called it *Polycarpæa*, from its reſemblance to *Polycarpon*; but ſuch a name is altogether untenable, and Ventenat therefore rejected it for the above. Vent. Fabl. du Regne Veg. v. 3. 240. (Polycarpæa; Lamarck. in Journ. d'Hiſt. Nat. v. 2. 1. t. 25. Dict. v. 5. 482.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Caryophyllei*, Linn. Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, concave, membranous-bordered, permanent leaves. *Cor.* Petals five, ovate-oblong, equal, rather ſhorter than the calyx, emarginate. *Stam.* Filaments five, awl-ſhaped, rather membranous at the baſe, alternate with the petals, and nearly as long; anthers ovate, of two cells. *Piſt.* Germen ſuperior, ovate, with three angles; ſtyle ſimple, the length of the ſtamens; ſtigma obtuſe. *Peric.* Capſule ovate, triangular, acute, of one cell, and perhaps three valves, encloſed in the permanent calyx. *Seeds* ſeveral, oval, a little compreſſed on one ſide, ſmooth, attached by threads to the baſe of the capſule.

Eſſ. Ch. Calyx of five leaves. Petals five, emarginate. Capſule three-ſided, of one cell, with ſeveral ſeeds.

1. H. *canarienſis*. (Illecebrum canarienſe; Linn. Suppl. 161. Willd Sp. Pl. v. 1. 1206. Polycarpæa teneriffæ; Lamarck, as above.)—Leaves ſpatulate, with a blunt point. Gathered by Mr. Maſſon and M. Lahaye in Teneriffe. Mr. Maſſon's own ſpecimen, in our hands, agrees exactly with ſome from the Paris garden, except that, being a wild one, its *ſtem* is more woody; which gave the younger Linnæus an idea of its being an arboreſcent plant, eſpecially as he was not aware of its growing proſtrate, though that circumſtance is evident on a due examination, even of this ſpecimen. We thus get rid of an uncouth ſpecific name, for one rather better and more uſual, though not excellent, all names of countries being liable to objection for ſuch a purpoſe. Many oppoſite, round, jointed, leafy, more or leſs downy, *branches* ſpring from the woody ſtem, which in their upper part are repeatedly forked in an alternate manner, and finally panicled, bearing innumerable crowded green and white *flowers* reſembling thoſe on *Illecebrum*, the ſilvery membranous *bracteas*, and borders of their calyx-leaves, giving them ſuch an appearance. The *leaves* are oppoſite, ſtalked, about an inch long, ſpatulate, entire, ſmooth, flat, with a little blunt

H A G

blunt point, and are accompanied by axillary tufts of rather ſmaller ones. *Stipulas* numerous, ovate, long-pointed, membranous, jagged, ſmall, browniſh.

2. H. *indica*. (Polycarpæa indica; Lamarck. in Journ. d'Hiſt. Nat. v. 2. 8. Dict. edited by Pourret, v. 5. 483. Achyranthes corymboſa; Linn. Sp. Pl. 296. Willd. Sp. Pl. v. 1. 1196. Polia arenaria; Lour. Cochinch. 164, not 204. Paronychia foliis ad genicula confertis acutis, floribus umbellatis; Burm. Zeyl. 184. t. 65. f. 2. Amaranthus folio tenuiſſimo, incano, &c. Bocc. Muſ. 44. t. 39.)—Leaves linear, acute, ſomewhat awned.—Native of ſandy ſea ſhores in Ceylon, Coromandel, and probably other parts of the Eaſt Indies. The *root* is woody. *Stems* ſhrubby at the baſe, about a foot high, aſcending, round, downy, repeatedly forked, denſely corymboſe at the top. *Leaves* numerous, oppoſite or quaternate, ſcarcely an inch long, ſeſſile, linear, acute, often awned, entire, flat, glaucous or hoary, with a prominent rib beneath; they are accompanied by axillary tufts of ſmaller leaves, as in the firſt ſpecies. *Stipulas* ovate or lanceolate, white, pellucid, jagged, with a very ſlender point. *Flowers* numerous, white or reddiſh, with ſilvery bracteas. In ſtarved ſpecimens the leaves are ſometimes ſhorter, and rather broader. Such a variety is exhibited in Plukenet, t. 86. f. 5, while f. 6, bad as it is in the flowers, approaches more to the uſual habit of the plant.

HAGARSTOON, in *Geography*. See ELIZABETH *town*.

HAGDANGER, a town of Sweden, in Angermanland; eight miles S.S.W. of Hernoſand.

HAGE, a town of Eaſt Frieſland; 15 miles N. of Embden.

HAGEDORN, FREDERIC, in *Biography*, born at Hamburgh in the year 1708, received an excellent education, and diſcovered at a very early age a good talent for writing poetry. By the death of his father while he was very young, he had little elſe to truſt to, in making his way in the world, but his own exertions and induſtry. In 1726 he went to Jena, where he applied moſt diligently to the ſtudy of the law for about three years, and in 1729 he publiſhed a ſmall collection of poems. In the ſame year he repaired to London with good recommendations to the Daniſh ambaſſador, who treated him with great kindneſs, and introduced him to the ſociety of ſuch perſons as could render him any ſervice, and through whoſe influence he was, in the year 1733, appointed ſecretary to the ſociety of Britiſh merchants at Hamburgh, an office which rendered him eaſy with reſpect to pecuniary matters, and which gave him acceſs to the beſt company. In the year 1738 he publiſhed his firſt book of "Fables," which brought him into notice, and from this period he frequently appeared before the public as author of various light but elegant productions; and many of them on important moral ſubjects. He was, when in England, a great admirer of Pope, and in 1742 he publiſhed a good paraphraſe of his "Univerſal Prayer." He died in the forty-ſeventh year of his age. By ſome of his biographers he has been compared with Pope, by others with Prior, whom he has in ſome of his pieces endeavoured to imitate. Few poets have taken more pains to poliſh their works than Hagedorn, and he is called by Wieland the German Horace. His works were colle ted two years after his death, and publiſhed at Hamburgh, ſince which there have been ſeveral editions of them. Gen. Biog.

HAGEN, in *Geography*, a town of Weſtphalia, in the county of Mark, containing three churches and ſome manufactures of cloth; ſix miles N.W. of Altena.

HAGEN, a town of the iſland of Rugen; 16 miles S.E. of Bergen.

HAGENAU, a town of Lower Saxony, in the duchy of Schwerin; 26 miles S.W. of Schwerin.

HAGENBURG, a town of Weſtphalia, in the county of Schauenburg; 15 miles W. of Hanover.—Alſo, a town of the archduchy of Auſtria; nine miles N.E. of Steyregg.

HAGENDORN, ERFROY, in *Biography*, a phyſician, was born at the little town of Wolaw, in Sileſia, in 1640. He graduated at Jena in 1668, and practiſed at Gorlitz with great reputation as an able phyſician, and a man of extenſive knowledge. Hence he was honoured with the appointment of phyſician to the court of Saxony, which he filled with great credit under the electors John-George II., III., and IV. He was attacked with a fit of apoplexy on the 27th of February, 1692, and died the ſame day, at the age of fifty-two years. He wrote ſeveral papers, which were printed in the memoirs of the Imperial academy, and alſo publiſhed the following works. "Martini Rulandi patris ſecreta ſpagyrica, &c." Jena, 1676, 12mo. "Tractatus phyſico-medicus de Catechu, ſive Terra Japonica," ibid. 1679, 8vo. "Cynoſbatologia," ibid. 1681, 8vo. "Hiſtoriæ phyſico-medicæ," 1690, 8vo. A poſthumous publication, entitled "Obſervationum et Hiſtoriarum medico-practicarum rariarum Centuriæ tres," appeared at Francfort and Leipſic, in 1698, in 8vo. Eloy. Dict. Hiſt.

HAGENIA, in *Botany*, ſo named by Lamarck in honour of Dr. Charles Godfrey Hagen, profeſſor at Koningſberg, author of a valuable work entitled *Tentamen Hiſtoriæ Lichenum, et præſertim Pruſſicorum*, and of an eſſay *De Ranunculis Pruſſicis*, the firſt publiſhed in 1782, the latter in 1784. Their author, born in 1749, is, as far as we know, ſtill living.—Lamarck. Illuſtr. t. 311. Willd. Sp. Pl. v. 2. 331. (Bankſia; Bruce's Travels, v. 5. 73, with a figure.)—Claſs and order, *Decandria Monogynia*. (*Octandria Monogynia*. Lamarck. Willd.) Nat. Ord. *Roſaceæ*, Juſſ.?

Eſſ. Ch. Calyx horizontal; its limb in five elliptical, permanent, enlarged ſegments. Petals five, acute, entire, four times ſhorter than the calyx. Stamens very ſhort.

1. H. *abyſſinica*. Willd. (Cuſſo, or Bankſia abyſſinica; Bruce, as above.)—A *tree*, whoſe branches are leafy at their extremities, and ſcaly with the baſes of footſtalks that are fallen. *Leaves* large, cluſtered, interruptedly pinnate, with an equal-ſized terminal leaflet; pinnæ five or ſix pair, nearly oppoſite, ſeſſile, lanceolate, a little unequal, ſerrated, hairy, heart-ſhaped at the baſe; the intermediate ones ſmall, round, notched, variable. *Stipula* membranous, entire, united to the footſtalk at each ſide. *Panicle* terminal, pendulous, ſtalked, about as long as the leaves, much branched, zig-zag, many-flowered. *Flowers* about an inch broad; their calyx pale yellowiſh-green; petals dull purpliſh-brown; anthers yellowiſh. We have no account of the fruit, and having never ſeen a ſpecimen, can only gueſs at the natural affinities of this very extraordinary plant, and attempt more correct botanical characters of it than have hitherto been given, for thoſe in Willdenow are certainly erroneous. That the genus is diſtinct from all hitherto known there can be no doubt, though Bruce was incompetent to give a ſcientific account of it, and no living or dried ſpecimens have as yet come under botanical inveſtigation.

HAGETMAU, in *Geography*, a town of France, in the department of the Landes, and chief place of a canton, in the diſtrict of St. Sever, 2½ leagues S. of St. Sever. The place contains 2392, and the canton 10,181 inhabitants, on a territory of 197¼ kiliometres, in 20 communes.

HAGGAI, a canonical book of the Old Teſtament, ſo called from the prophet of that name, who in all probability was born at Babylon, from whence he returned with Zerubbabel.

This

This prophet, in the ſecond year of Darius, or the five hundred and twentieth before Chriſt, exhorted the Jews after their return from their captivity, to finiſh rebuilding the temple, which they had intermitted for fourteen years. His remonſtrances had the deſired effect; and to encourage them to proceed in the work, he aſſured them from God, that the glory of this latter houſe ſhould exceed the glory of the former; which was accordingly fulfilled when Chriſt honoured it with his preſence: for with reſpect to the building, this latter temple was not to be compared with the former. The ſtyle of this prophet is altogether proſaic.

HAGGARD, in *Falconry*, a hawk, or falcon, not taken in the neſt; but after ſhe had been enured to liberty, and preying for herſelf. The word is French, and ſignifies *fierce*; ſome derive it from the Latin *agreſte, wild*; others from the German *hag*, incloſure, fortified place. Whence Mr. Huet obſerves, the word haggard is ſometimes applied to a man who becomes hardy and proud, in confidence of the ſtrength of the place he is in.

Haggard hawks are hard to tame, and bring under diſcipline.

HAGGEIN, in *Geography*, a mountain of Switzerland, in the canton of Schweitz, remarkable for its triple-top and formidable aſpect; from it extends a chain, ſeparating this canton from Uri on the N. and Glaris on the E.

HAGGS, a kind of fiery meteor appearing on men's hair, or horſes' manes; now known to be electrical phenomena.

HAGI, or HADDI, in *Geography*, a kingdom of Africa, in the deſert of Zanhaga, on the borders of the river St. John, and near the Atlantic ocean.

HAGIAM, in the *Materia Medica*, a name given by ſome of the Arabian phyſicians to a kind of *ſchœnanth*, or camel's hay. The Greeks made ſeveral kinds of this, according to the places from whence they received it; the ſchœnanth of different countries differing in virtue: but the Perſian was, in many ages, eſteemed the beſt kind; and this is probably what the Arabs called *hagiam*. The interpreters of Avicenna leave this word wholly unexplained. Garcias, according to what ſkill he had in the Arabic, ſuppoſes it the city Damaſcus, and given to ſuch ſchœnanth as came from that part of the world; but this ſeems erroneous. The Arabs called all other nations barbarians; and this term gentiliſm, or barbariſm, was, in their language, expreſſed by the word *hagiam*; they hated the Perſians beyond all other nations in the world, and called them hagiam, by way of eminence, and therefore hagiam and Perſian were a ſort of ſynonymous words. It is probable they had their ſchœnanth principally from Perſia; and that this, whether better or worſe than the Nabatæan ſchœnanth of their own country, was diſtinguiſhed by the epithet of *foreign*, and that with the word by which they expreſſed Perſian.

HAGIAN, in *Geography*, a town of Arabia Petræa, near the ſcite of the ancient Petra.

HAGIAZ, a town of Arabia, in the province of Hedsjar; 120 miles N. of Medina.

HAGIBESTASH, a town of Aſiatic Turkey, in Caramania; 25 miles S. E. of Kirſhehr.

HAGIOGRAPHA, a name given to part of the books of Scripture, called by the Jews *Cetubim*. See CANON.

The word is compounded of ἅγιος, *holy*, and γράφω, *I write*. The name is very ancient: St. Jerom makes frequent mention of it: before him, St. Epiphanius called theſe books ſimply Γραφαὶ.

The Jews divide the ſacred writings into three claſſes; the Law, which comprehends the five books of Moſes; the Prophets, which they call *Neviim*; and the *Cetubim*, כתובים, called by the Greeks, &c. *Hagiographa*; comprehending the book of Pſalms, Proverbs, Job, Daniel, Ezra, including alſo the book of Nehemiah, Chronicles, Canticles, Ruth, the Lamentations, Eccleſiaſtes, and Eſther.

The Jews ſometims call theſe books the Writings, by way of eminence, as being written by immediate inſpiration of the Holy Spirit. Thus, ſays Kimchi, in his preface to the Pſalms, Maimonides in *More Nevoch*, and Elias Levita in his *Thiſbi*, under the word כתב.

They diſtinguiſh the hagiographers, however, from the prophets; in that the authors of the former did not receive the matters contained in them by the way called Prophecy, which conſiſts in dreams, viſions, whiſpers, exſtaſies, &c. but by mere inſpiration, and direction of the Spirit.

HAGIOSIDERON, or HAGIOSIDIRON, compounded of ἅγιος, *holy*, and σίδηρος, *iron*. The Greeks, who are under the dominion of the Turks, being prohibited the uſe of bells, made uſe of an iron wherewith to call people to church, called *hagioſideron*.

Magius gives us the deſcription of a hagioſideron which he had ſeen. It is a plate of iron, about three inches broad, and ſixteen long, faſtened by the middle to a chain or cord, whereby it is ſuſpended at the church-door. On this they ſtrike with an iron hammer, with ſome meaſure and cadence, ſo as to make no diſagreeable noiſe.

They alſo carry a hagioſideron before the prieſt, in a proceſſion of the ſacrament to any ſick perſon, beating on it from time to time, to advertiſe the people to adore it; much as in the Romiſh church they do with a bell.

HAGISA, in *Geography*, a town of Arabia, in the province of Hedsjar; 112 miles S.E. of Medina.

HAGLIAR, a town of Spain; 22 miles S.S.E. of Aleppo.

HAG-MASTER, in *Engineery*, is a perſon who undertakes the cutting of a length of canal, or other job of work by meaſure, and employs labourers or navigators, *by the day*, to execute it.

HAG's-*Head*, in *Geography*, a cape of Ireland, in the county of Clare. N. lat. 52° 55′. W. long. 9° 23′.

HAGSHULT, a town of Sweden, in the province of Smaland; 25 miles S. of Jonkioping.

HAGSNARE, in *Rural Economy*, a term ſometimes employed, provincially, to ſignify a ſtool or ſtub, from off which coppice wood has been cut or felled.

HAGUE, in *Geography*, uſually eſteemed a village of Holland, though the number of its inhabitants has been eſtimated at 36,000. It is ſituated about two miles from the ſea, in former times the reſidence of the ſtadtholder, the ſtates-general, and the ſtates of the province. The court, or palace, contained ſeveral chambers allotted to the different branches of government, beſides the apartments of the ſtadtholder. The ſtates-general met in a room, which contained 26 chairs, for the uſual number of the members. The French have deſpoiled it of its cabinet of natural hiſtory, and probably of the moſt curious books and pictures. It has been ſaid, that this village contains more magnificent houſes, than occur in the like ſpace in any city of modern Europe. The ſtreets are long and ſpacious, and ſeveral of them adorned with rows of trees. It is governed by its own magiſtrates, which are a bailiff, whoſe office is for life, three burgomaſters, annually changed, ſeven echevins, 12 common council, a penſionary, ſecretary, and treaſurer. On the N. of the town is

a noble

a noble grove, with alleys of oak and beech, leading to the palace of the (late) ſtadtholder; but the pleaſanteſt road is that to Schevening, a village on the ſhore, two miles to the N.W. through four rows of lofty elms. The Hague is pleaſantly ſituated, in a dry ſoil, upon ſomewhat of an eminence, compared with the reſt of the country; the air is pure, and the environs are delightful; 32 miles S.W. of Amſterdam, and 12 N.W. of Rotterdam. N. lat. 52° 4′ 10″. E. long. 4° 17′ 30″.

HAGUENAU, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the diſtrict of Straſburgh; 15 miles N. of Straſburgh. It is ſituated on the Motter, in the middle of a foreſt which bears its name; and it was fortified by Frederick I., who made it an imperial town, and called it the chamber of the empire, becauſe in it were preſerved the imperial ornaments, under the houſe of Swabia. The place contains 7094, and the canton 14,567 inhabitants, on a territory of 195 kiliometres, in 16 communes. The ſurrounding land is ſandy, and unproductive, and the commerce is inconſiderable: the principal articles being madder and tobacco. N. lat. 48° 50′. E. long. 7° 52′.

HAGWORM, in *Rural Economy*, a name which is ſometimes provincially applied to the adder, an animal which is venomous, and delights in ſituations of the new-cut coppice wood kinds.

HAHA, in *Geography*, a bay on the S. coaſt of Labrador. N. lat. 51. W. long. 59° 10′.

HAHN, Simon Frederic, in *Biography*, was born at Bergen, in the duchy of Hanover, in the year 1692. He ſoon acquired an extenſive knowledge of the learned languages, and when he was only fourteen years of age, he pronounced, at the univerſity of Hall, a Latin harangue on the origin of the monaſtery of Bergen, which was printed. He next appeared as the continuator of the Chronicle of Bergen by Meibomius, and its charter from Otho the Great. His next work was lectures on hiſtory, which were publiſhed before he was twenty years of age, and which obtained for him a reputation that cauſed him to ſucceed the profeſſor Eccard in the profeſſorſhip of hiſtory at Helmſtadt. In 1725 he ſucceeded the ſame perſon as hiſtoriographer and librarian to the elector of Hanover. He died while in the diſcharge of theſe offices, at the age of thirty-ſeven. His principal works are "A Hiſtory of the Empire," in the German language, of which the firſt four volumes appeared in 1731; and "Collectio Monumentorum veterum et recent. ineditorum." Moreri.

HAHRAR, in *Geography*, a town of Egypt; 21 miles E. of Tineh.

HAI, a city of China, of the ſecond rank, in the province of Kiang-nan. N. lat. 34° 32′. E. long. 117° 0′.

HAJAR, a town of Arabia, in the province of Hedsjar; 150 miles N. of Medina.

HAICHAN-TAO, an iſland in the Chineſe ſea; near the S.W. coaſt of Corea. N. lat. 34° 30′. E. long. 124 32′.

HAJE, in *Zoology*, the name of a viper that inhabits Egypt, and which, when irritated, inflates its throat. Some imagine this to be the true aſp of the ancients. See Coluber *Aſpis*, Linn.

HAIFAR, in *Geography*, a town of Paleſtine, near the coaſt of the Mediterranean, at the foot of mount Carmel, and on the S. ſide of a bay oppoſite to Acre. It has tolerably good anchorage, but no harbour. It has the remains of a caſtle, and of two churches, one ſerving for a magazine, and the other for a caravanſera; 5 miles S.E. of Acre.

HAIGERLOCH, a town of Germany, in the county of Hohenberg; 44 miles S.E. of Straſburgh. N. lat. 48° 20′. E. long. 8° 54′.

HAIGH, a townſhip in the pariſh of Wigan, and county of Lancaſter, England, is chiefly worthy of notice, in a topographical point of view, for a ſingular ſpecies of coal obtained here, and called Cannel coal. This is generally found in large blocks, is as black as jet, and, from its hard compact ſubſtance, will bear a beautiful poliſh. The beds, or ſtrata, are about three feet thick; they dip one yard in twenty, and are at conſiderable depths, with a black maſs above and below. This coal is peculiarly pleaſant for burning, being very clean, and producing a vivid hot flame. It is often turned in a lathe, and manufactured in ſnuff-boxes, and various ornamental utenſils. At Haigh-hall is a ſummer-houſe, built entirely with this coal. For its mineralogical character, &c. ſee under the term Coal, ſection 11, family black-coal, vol. viii. of this work.—Haigh-hall, the ancient ſeat of the Bradſhaighs, now belongs to the earl of Balcarras. Haigh contained, in 1801, 118 houſes, and 798 inhabitants. See Beauties of England and Wales, vol. ix.

HAII, a name uſed by the Braſilians for an animal we call the ſloth or *ignavus*. The word ſeems pronounced by the creature itſelf, as its common note, and thence became uſed as its name. See Bradypus.

HAJIPOUR, in *Geography*, a town of Hindooſtan, in Meywar; 20 miles S. W. of Cheitore.

HAIL, or Hailstones, in *Meteorology*, conſiſt of drops of rain congealed in their deſcent. The occaſion of hail, and the extaordinary circumſtances which ſometimes accompany the phenomena, have excited the attention of philoſophers of ſucceſſive ages, and have produced many conjectures and opinions, which, in the preſent improved ſtate of the ſciences, are ſcarcely worthy of mention. Deſcartes imagined clouds to be frozen, and that portions of them were partially melted and detached; theſe, in their deſcent, were again frozen and became hail. The diſcoveries in electricity opened the way for a much more refined hypotheſis. Signior Beccaria ſuppoſes hail to be formed in the higher regions of the air, where the cold is intenſe, and where the electric fluid abounds. By the electric attraction a great many particles of water are brought together; theſe are frozen, and in their deſcent they collect other particles; theſe laſt form the outſide of the hailſtones, leſs denſe and hard than the central parts, becauſe the temperature in deſcending is more moderate. Agreeably to this hypotheſis, hailſtones and drops of rain are found to be leſs on the tops of mountains than in vallies; and both are larger, all other circumſtances the ſame, in proportion as the atmoſphere exhibits ſtrong marks of electrical agencies. Thus, large hailſtones and large drops of rain, are univerſally known to be the frequent concomitants of thunder and lightning. Beccaria obſerves, that as motion promotes freezing, ſo the rapid motion of the electrified clouds may promote that effect in the air. This laſt remark appears injudicious, as thunder-clouds have generally leſs motion than others.

Though the theory of Beccaria is incomparably more plauſible than that of Deſcartes; yet it contains much that is hypothetical. That hail is formed in the high and cold regions of the atmoſphere is unqueſtionable; and that the electric fluid abounds there as much as it abounds in the lower regions, is as probable as the contrary. But why ſhould the electrical attraction form an aggregate of particles of water? Are not they all electrified alike, and conſequently

quently indifferent to each other in regard to attraction and repulſion? Or, if the effect of the electrical attraction is to collect the particles of water diffuſed through the air, how comes it to paſs that it ever allows them to ſeparate again? Theſe, and many other queſtions might be put, to which no anſwer could be given, or at beſt very unſatisfactory ones. But, waving all theſe objections, it ſhould appear from the hypotheſis, that hail is a natural and ordinary production, and might be expected as frequently as rain; whereas the quantity of hail, at an average, is not perhaps more than $\frac{1}{100}$ part of the quantity of rain, and muſt therefore be conſidered as a phenomenon out of the ordinary courſe of nature. Theſe conſiderations render the theory of Beccaria, as well as all other electrical theories, very inadequate to explain the phenomena.

Before we enter upon any other explanatory view, it may be proper to ſtate the general phenomena more minutely, as reſulting from obſervation.

Hail is moſt frequently attendant upon thunder; and it is upon ſuch occaſions that the hailſtones are ſometimes enormouſly large and deſtructive, as the experience of many people, and authentic records ſufficiently teſtify. Hiſtory indeed furniſhes us with ſome extravagant and incredible accounts of hail accompanying thunder. Mezeray, in the ſecond volume of his hiſtory of France, p. 339, mentions hailſtones that fell in Italy, 100lbs. in weight. Dr. Halley, in the Philoſophical Tranſactions, relates ſtorms in which the hailſtones weighed from five ounces to half a pound, and were 13 or 14 inches in circumference. No doubt ſuch accounts are frequently exaggerated; but it is probable that people are often deceived by taking up maſſes that have been aggregated and cemented by congelation after their fall. However this may be, hailſtones do frequently fall much exceeding any drops of rain in magnitude. Hailſtones are generally more or leſs opaque, hardeſt in the centre, and the outſide forms a kind of coating, not unlike the hoar-froſt on the ſurface of a veſſel containing a freezing mixture. The figure of hail is moſtly globular, but ſubject to conſiderable irregularities. Hail-ſhowers take place much the ſame in all ſeaſons of the year, but rather leſs frequently in ſummer; yet in that ſeaſon they are more violent when they do occur. Mr. Dalton obſerves (Meteorology, p. 46.), that the winds, which bring hail-ſhowers in the north of England, are always S.W. W. or N.W.; and the barometer is generally low. He ſtates the reſult of five years obſervations on hail-ſhowers, in the different months of the year, to be as follows:—

Months.	No. of days on which hail was obſerved.
January	11
February	7
March	5
April	8
May	11
June	6
July	2
Auguſt	1
September	6
October	7
November	7
December	13

It is preſumed that hail rarely, if ever, appears in the torrid zone; and it has been aſſerted that it rarely occurs in latitudes above 60°; probably it is confined chiefly to the temperate zones.

Now, as *rain* is the uſual form in which water is precipitated from the atmoſphere in ſummer, and *ſnow* that in winter, the general theory of the precipitation, or, more properly, of the *formation* of rain and ſnow in the atmoſphere, will be diſcuſſed under the heads of Rain and Snow. In the preſent inſtance, we have only to ſhew what are the extraordinary circumſtances which occaſionally convert the *rain* into *hail*; for, that the central part of every hailſtone originates in a drop of rain, according to the common opinion, is too obvious to require proof.

It is a well known fact in meteorology, that in ſerene weather the temperature of the atmoſphere gradually decreaſes above the ſurface of the earth in proportion as we aſcend. The quantity of variation is commonly about 1° for 300 feet perpendicular aſcent, or about 18° for one mile. Hence, then, in the ordinary courſe, when any precipitation takes place in the higher regions, it will gradually increaſe in temperature as it deſcends. Rain will continue to be rain during the whole deſcent; and ſnow to be ſnow, unleſs the increaſe of heat change it into rain. But if by ſome means the general law of temperature in the atmoſphere ſhould be inverted; if a warm, vapoury ſtratum of air ſhould, temporarily, become ſuperior in ſituation to a cold ſtratum, rain might be precipitated from the warm ſtratum, and this, in falling through the cold ſtratum, might be frozen into globules of ice; theſe would then have to deſcend through another inferior and warmer ſtratum of vapoury air, where the cold particles of ice would conſtantly condenſe more and more vapour on their ſurfaces; theſe ſurfaces would become leſs hard as the temperature approached the freezing point, and perfectly reſemble the opaque icy coating of a veſſel containing a freezing mixture, agreeably to obſervation.

Now, as hail is attended with a low barometer, and this uſually indicates ſqually or tempeſtuous weather, it is highly probable that ſuch inverſions of temperature in the atmoſphere may occur as have been pointed out. Particularly when the barometer is low, a ſudden influx of the air, which muſt always be tending from the equator toward the poles in the higher regions, may induce with it a higher temperature than the latitude and ſeaſon can ſupport; and in ſome caſes a temperature, ſuch as to be ſuperior to that of the ſtratum of air beneath. See Wind.

Another cauſe may ſubſiſt for the inverſion of temperature in the atmoſphere. If, on any occaſion, as during the heat of ſummer, a ſtratum of air next the earth's ſurface ſhould be heated, from local circumſtances of reflection, &c. beyond a certain point, it might become ſpecifically lighter than the incumbent ſtratum of air, and change places with it. This would produce a tumultuous agitation of the atmoſphere, and irregularities not otherwiſe to be obſerved. See Hurricane.

Thunder uſually accompanies violent hail-ſhowers; and thunder is well known to be moſt prevalent in that ſeaſon of the year when the atmoſphere is moſt replete with vapour. When the quantity of ſteam in the air is a maximum, any commotion or cauſe of precipitation muſt be ſuppoſed to produce a greater effect in that caſe than if the total quantity was only one-half or leſs, and all other circumſtances the ſame. Hence it ſhould ſeem that the extraordinary falls of hail are occaſioned, not ſo much from a ſuperabundance of electricity, as of ſteam in the atmoſphere. See Thunder, &c.

HAILE, a *ſea*-term, ſignifying either to call to a ſhip, to know from whence ſhe comes, and whither ſhe is bound, or elſe to ſalute her, and wiſh her well.

HAILLAN, Bernard de Girard du, in *Biography*, born at Bourdeaux, about the year 1535. He became

known while he was a very young man, by his poems and tranſlations, but in 1571 he was appointed hiſtoriographer to Charles IX. of France; and on this occaſion he renounced the religion in which he had been educated, and embraced the tenets of the Roman Catholics. He was in the confidence of Henry III. before he came to the throne, and in 1576, dedicated to that prince his "Hiſtory of France" for which he received various honours and emoluments. He accompanied Noailles, biſhop of Acqs, on his embaſſies to England and Venice. He died in 1610, leaving behind him ſeveral works, but that by which he is principally known is his "Hiſtory of France from Pharamond to the death of Charles VII." which was the firſt body of French hiſtory written in that language. Moreri. Bayle.

HAILSHAM, in *Geography*, a pariſh and market town in the hundred of Dill, and rape of Pevenſey, Suſſex, England, is 12 miles from Lewes, the county town, and 57 from London. The town conſiſts of 132 houſes, inhabited by 897 perſons. Here is a ſmall weekly market on Wedneſdays. At Michelham, near this town, was a priory of black-canons, founded by Gilbert de Aquila in the time of king Henry III.

HAIMEN, in *Geography*, a town of the kingdom of Corea, in the province of Tchu-ſin; 90 miles S.W. of Kingkitao. N. lat. 37° 48'. E. long. 126° 42'.—Alſo, a town of China, in the province of Tche-kiang; 20 miles S. of Tai-cheou.

HAIMER, Le, a town of Dar-fur; 50 miles N.N.E. of Cobbé.—Alſo, a town of Nubia; 60 miles S. of Syené.

HAIN, in *Agriculture*, a term ſometimes made uſe of to ſignify the ſhutting up paſture lands from being eaten by live ſtock. It likewiſe ſignifies the raiſing or heightening a rick or ditch on the borders of the ſea, in the county of Norfolk.

HAINAN, in *Geography*, an iſland of China, belonging to the province of Quang-tong, and bounded on the N. by the province of Quang-ſi, on the S. by the channel, formed between the bank Paracel and the eaſtern coaſt of Cochinchina, on the W. by the ſame kingdom and part of Tong-king, and on the E. by the Chineſe ſea. Its extent from E. to W. is between 60 and 70 leagues, and from N. to S. 45; ſo that it is about 160 leagues in circumference. Its capital is Kiun-tcheou-fou; which ſee. The natives of this iſland are very deformed, ſmall of ſtature, and of a copper-colour; both men and women wear their hair thruſt through a ring on their forehead; and above they have a ſmall ſtraw-hat, from which hang two ſtrings that are tied under the chin. Their dreſs conſiſts of a piece of black or dark-blue cotton cloth, which reaches from the girdle to their knees; the women have a kind of roller of the ſame ſtuff, and mark their faces from the eyes to the chin with blue ſtripes made with indigo. Among the animals of this iſland is a curious ſpecies of black apes, having the ſhape and features of a man; they are ſaid to be very fond of women; here are alſo crows with a white ring round their necks, ſtarlings, which have a ſmall crefcent on their bills, black-birds of a deep blue colour, with yellow ears riſing half an inch, and a multitude of other birds, remarkable for their colour or their ſong. Beſides mines of gold and lapis lazuli, which enrich this iſland, it produces an abundance of various kinds of curious and valuable wood; ſome of which has been tranſported to Peking, at an immenſe expence, to adorn an edifice, intended for a mauſoleum. The moſt valuable is called by the natives "Hoali," and by the Europeans, roſe or violet wood, from its ſmell; it is very durable, and of unrivalled beauty; and it is, therefore, reſerved for the uſe of the emperor. Hainan, on account of its ſituation, riches, and extent, deſerves to be ranked among the moſt conſiderable iſlands of Aſia. Not far from it is another ſmall iſland, commonly called "San-cian." It is celebrated by the death of St. Francis Xavier; whoſe tomb is ſtill to be ſeen on a ſmall hill, at the bottom of which is a plain, covered on one ſide with wood, and on the other ornamented with ſeveral gardens. This iſland contains five villages, inhabited by poor people, who ſubſiſt merely on rice and the fiſh they catch. N. lat. 18° 15', to 20° 2'. E. long. 108° 4', to 110° 20'.

HAINAUT, *County of*, late one of the provinces of the Catholic Netherlands, bounded on the N. by Flanders and Brabant, on the E. by Brabant, the county of Namur, and biſhopric of Liege, on the S. by France, and on the W. by France and Flanders. Its greateſt extent from N. to S. was about 48 miles, and from E. to W. 55. The air is temperate; the ſoil produces corn in abundance; the rich paſtures feed large herds of cattle, and the ſheep yield good wool. Its woods ſupply timber for building, and fuel for burning. It has mines of coal and iron, and quarries of beautiful marble, ſlate, and other uſeful ſtone. The principal rivers are the Scheldt, the Selle, the Haiſne, the Sambre, and the Dender. By the peace of Luneville, the whole of this county was ceded to France. The capital is Mons.

HAINBURG, or Haimburg, a town of Auſtria, on the Danube, having a manufacture of cloth; 20 miles E.S.E. of Vienna. N. lat. 48 6'. E. long. 17°.

HAINFELDEN, a town of Auſtria; 20 miles S.W. of Vienna.

HAINGEN, a town of Germany; 21 miles W.S.W. of Ulm.

HAIR, or Hayr, a country of Africa, in the deſert of Sahara, E. of Zanhaga, and extending about 60 miles. The air is temperate, and the ſoil in many places fertile. In the ſouthern parts manna is collected. The chief town is called Hair or Terga. N. lat. 23° 30' to 25° 20'. E. long. 1° to 4°.

Hair, in *Comparative Anatomy*, is the proper covering of the ſkin of mammalia, to which it appears to be excluſively confined. The hair-like tufts found on the bodies of young birds do not grow exactly like hair in general, but rather in the manner of feathers, to which they are in fact appendages. (See article Feathers.) The hairs of inſects are proceſſes of the ſhell or ſkin, which they reſemble in compoſition. The ſetæ of worms alſo do not appear to grow from a root, but to be placed in cells made by reflections of the ſkin; in the aphrodita aculeata, and other worms, we have obſerved that the hairs are caſt with the cuticle.

The common form of a hair is that of a round fibre, which is thickeſt next the root, and gradually diminiſhes until it ends in a point. The hairs on the tail of the *hippopotamus* are flattened, and thoſe on the body of the *great ant-eater*, (*myrmecophaga jubata*,) are broad and flat, and have a longitudinal furrow on both ſurfaces, ſo that each hair reſembles a blade of graſs. The whiſkers of the *ſeal* have ſomewhat a knotted appearance. When the hairs are ſtiff, and nearly of the ſame thickneſs throughout, as in the *hog*, &c. they are called *briſtles*; the hair of *negroes* and many of the *Biſulca* appears crimped or frizzled, and is thence called *wool*. *Fur* is the fine ſoft twiſted hair that is found on ſeveral of the *digitigrade* and *ſaltigrade* quadrupeds. The horny ſpines which diſtinguiſh the *porcupine*, *hedge-hog*, *tenrecs*, and *echidna*, and the ſcales of the genus *manis*, reſemble in their ſtructure and mode of growth common hair, although they differ much from it in external appearance. (See articles Scales and Spines.) Many other varieties might be mentioned, but the

the deſcription of the external form and the colour of hairs belongs to the natural hiſtorian.

All true hairs whatever may, by their figure, agree in certain circumſtances. They are all compoſed of a ſubſtance of a horny nature; they grow upon vaſcular pulps, which, with the tubular roots that ſurround them, are incloſed in bulb-ſhaped capſules or inveſtments, that are ſituated within the ſkin.

The minute parts which are concerned in the production of ſmall hairs, ſuch as thoſe which grow on the human head, or the bodies of quadrupeds in general, cannot be eaſily diſtinguiſhed. In theſe inſtances the bulbs appear to be ſhort tranſparent membranous tubes, which permit the root of the hair to be ſeen through them. They uſually contain a clear gelatinous fluid, and ſometimes a ſmall drop of blood. Theſe capſules have but a ſlight adherence to the ſub-cutaneous ſubſtance, or to the ſkin; as frequently on pulling out a hair the bulb comes along with it. The bulbs are larger in proportion as the hair is young. The pulp on which the hair is formed paſſes through the bottom of the capſule, in order to enter the tube of the hair, into which it penetrates for a ſhort diſtance, never in common hairs, reaching as far as the external ſurface of the ſkin.

The ſtructure and mode of growth of ſome large hairs, ſuch as the whiſkers of the digitigrade and ſaltigrade quadrupeds, can be clearly diſcerned with a common lens; and in the whiſkers of the *ſeal* and *walrus* they are ſufficiently plain to the naked eye. In all theſe inſtances, the bulb in which the whiſker is implanted is evidently compoſed of parts of different ſtructures. The external inveſtment is rather thin in the *ſeal*, but thick in the *hare* and *rabbit*; it is a tough fibrous ſubſtance, approaching, in the ſwimming mammalia, the nature of horn. It has but a ſlight connection with the adjoining cellular ſubſtance; it is very deficient in vaſcularity, and appears to be an envelope, in many reſpects analogous to the external ſheath of feathers.

The next inveſtment of the root of the whiſker is ſpongy in its texture; it is compoſed of an immenſe number of membranous cells, into which the numerous veſſels that are diſtributed to this part of the bulb appear to pour out their blood. In the genus *lepus* the cellular ſtructure is compact, irregular, and minute, and is formed by a fine reticulation of the membrane. In the *ſeal* nearly the firſt half of the ſpongy inveſtment is alſo of a cloſe reticulated ſtructure; about the middle of it there is a large circular cell, which is filled by a clotted fibrous maſs, reſembling a coagulum of blood, and the ſucceeding portion is compoſed of thin circular cells, formed by folds of the membrane arranged in a tranſverſe direction.

The ſpongy portion of the bulb is only united to the external envelope at the two ends.

In all whiſkered animals, the maxillary branches of the fifth pair of nerves are prodigiouſly large, and form a very intricate plexus beneath the integuments of the ſnout, the principal branches from which appear to terminate abruptly at the baſes of the bulbs of the whiſkers. Anatomiſts are not agreed with reſpect to the deſtination of the nerves of hairs; ſome have aſſerted that they entered the root of the hair; but Haller, Bichat, and others, were not ſatisfied that the nerves penetrated the bulb. We have, however, ſucceeded in tracing the courſe of the nerves of the whiſkers of the *ſeal* very diſtinctly. The large nerves, which arrive at the baſes of the bulbs, ſuddenly diminiſh in ſize, and are diſtributed in ſoft, fine branches, to the ſubſtance of the ſpongy inveſtment. The deſign of this organization is evidently to render the whiſkers delicate inſtruments of touch; it may, therefore, ſtill be queſtioned whether the bulbs of common hair are ſupplied by nerves in the ſame manner.

The third or internal inveſtment of the bulb forms the immediate ſheath to the root of the whiſker; it is thin and membranous, and is cloſely connected to the ſpongy portion of the bulb, to which it ſhould, perhaps, be conſidered as an internal tunic; their membranes ſeem to be continuous.

All the parts compoſing the bulb are perforated at each extremity; at the external end, to give paſſage to the ſhaft of the hair, and at the internal, to admit the pulp, which penetrates the cavity of the hair.

The bulbs of hogs' briſtles are very large and irregularly ſhaped at the root, and appear to be glandular in their ſtructure.

Duverney ſtates that the *pulp* ariſes from the bottom of the external envelope of the bulb, but it appears to us to be furniſhed by the ſub-cutaneous ſubſtance, in the ſame manner as the vaſcular pulps of feathers.

The pulp of whiſkers is a very elongated cone, with a ſpherical enlargement at its baſe. Its pointed extremity paſſes in the tube of the whiſker for ſome way beyond the ſurface of the ſkin; and hence when a whiſker is cut off cloſe to the ſkin, the pulp being wounded, the whiſker becomes deformed in its growth, producing a knob or bulb at its extremity.

The ſtructure of the pulp is evidently ſpongy. Duverney has deſcribed it as being compoſed of very fine membranous cells or valves, which permit the blood to aſcend in it, but not deſcend. The pulp is ſupplied by one artery, that divides into innumerable branches, which, when injected, render the whole perfectly red. The pulp far exceeds in vaſcularity the ſpongy envelope of the bulb, although the latter is deſcribed by Duverney as receiving numerous blood-veſſels, which ſend off millions of branches.

The office of the pulp is to ſecrete the matter of which the hair is compoſed.

The hair is originally contained within the cavity of the bulb. In the *elephant* there are many hairs which do not come out of the ſkin. When the hairs make their appearance, they carry with them a portion of the cuticle, which is afterwards caſt off in fine, branny ſcales. Bichat denies the fact of the hair elevating the cuticle upon it as it grows. He ſays the hair is as thick before it appears upon the ſkin as it is afterwards. That in pulling it out of the ſkin, provided it be detached at the root, no reſiſtance is experienced. That if the hair was enveloped by the epidermis it would be thrice its preſent thickneſs: and laſtly, that no appearance of the epidermis accompanying the hair is ſeen when the latter is pulled out of the ſkin; but on the contrary, a depreſſion is perceived at the place where the hair is extracted. Bichat has not taken into conſideration the neceſſary wearing and deſtruction of the cuticle elevated upon the hairs; and, conſequently, its ultimate diſappearance. The portion of a hair which is contained within the bulb is called the *root*, and that which projects beyond the ſkin the *ſhaft*. Although the one part is gradually converted into the other, they have apparently a different compoſition. The root, as long as the hair continues to grow, is ſoft and pulpy, and nearly colourleſs, while the ſhaft is hard and horny in its texture, and of ſome determined colour.

Every hair contains a tube, or is hollow interiorly, and admits, as before mentioned, the pulp for a greater or leſs diſtance. As the pulp is intended for the nutrition of the hair, it is found to extend only to that portion of the hair which is in a ſtate of growth; and in thoſe which are deciduous, or are caſt at particular ſeaſons of the year, ſuch as the hairs covering the bodies of quadrupeds, the pulp

becomes entirely obliterated before the period of ſhedding the hair, and its root is converted into a ſolid pointed maſs. The end of a briſtle forms an irregular ſolid bulb before it is caſt, from which it is ſo well conſtructed for being employed as a needle by ſhoemakers.

The hair of the human head and pubis, that of the beards of man and quadrupeds, and the hair of the tails and manes of beaſts, are not deciduous, and therefore always have the roots ſoft and filled by the pulp.

All that portion of the tube of a hair to which the pulp does not extend, is filled with a dry pith or ſeries of cells containing air. Duverney ſays that when a hair is viewed tranſverſely in a microſcope, ſome of the bubbles of air are often perceived. He ſuppoſes that the air is furniſhed by the pulp for the nutrition of the hair, but there is every reaſon to believe that it is derived from the atmoſphere in conſequence of the vacuum produced by the degeneracy or retreat of the vaſcular pulp, in the ſame manner as the air of feathers is attracted from the external element. See FEATHERS.

The whiſkers of the *ſeal* ſhew the appearance of a tube almoſt to the very point: ſmall hairs are probably alſo hollow throughout, as every part of them has been moulded upon the pulp; every hair ſhould, therefore, be conſidered as a tube ſhut at the pointed extremity, and filled either with a vaſcular pulp, or a medulla formed of cells reſembling the dry pith of vegetables.

The ſubſtance of a hair perfectly reſembles horn in its compoſition. In briſtles and ſeveral other kinds of hair, this horny ſubſtance is arranged in fibres in the ſame manner as the woody fibres of a cane.

M. Bichat has given a different account than the above of the ſtructure of hairs. He deſcribes them as being compoſed of two diſtinct parts. The firſt is the external envelope, which he conſiders as having all the properties of the epidermis, that it does not poſſeſs vitality, is of an unperiſhable nature, and is devoid of colour. The ſecond he calls the interior ſubſtance of the hair, the nature of which he does not pretend to underſtand; but to it he aſcribes all the vital properties, the peculiar characters and colour of the hairs, and all the changes and diſeaſes to which it is liable. (Anatomie Generale, tome 4.) In this account Bichat has not ſhewn his uſual accuracy of obſervation. The only interior ſubſtance to be found in a hair, except the pulp towards the root, is the pith or medulla already mentioned; to which there is no reaſon to attribute any peculiar properties. The colouring matter certainly does not reſide in it, but pervades the ſubſtance of the horny tube of the hair, to which it communicates an uniform ſtain or dye, in the ſame manner as the ſubſtance of a horn or hoof is coloured.

Bichat ſuppoſes that there is a ſpecies of circulation in the interior ſubſtance of the hair, by which he explains the changes of colour, and the ſympathy which is well known to exiſt between the hair and many important organs of the body. If, however, theſe effects are produced by any vital action, it muſt go on likewiſe in the horny ſubſtance of the hair, which is the ſeat of many of thoſe effects. The fibrous ſtructure of the hair ſeems calculated to admit that ſort of movement or circulation of the juices which takes place in plants; and an organic action in the ſubſtance of hairs muſt be admitted to exiſt, in order to account for the changes to which it is ſubject. All hair undergoes ſome alteration in its colour. It firſt grows darker, and ultimately lighter. Theſe changes are to be obſerved even in thoſe hairs which are ſhed every year; but they are moſt remarkable in thoſe that continue to grow during the life of the animal. The hair of the human head is almoſt always lighter, and ſometimes of a different tint in childhood, than it becomes afterwards; and as old age advances, it experiences in moſt people who do not become bald the remarkable change into grey. In the permanent hair of quadrupeds, ſimilar alterations of the colour take place at the different ages of the animal; and even the ſucceſſive coats of deciduous hair are in a degree ſubject to the ſame variations; thus a horſe which is a dark grey when young, becomes white by age.

We have eſſayed to trace the progreſſion of the colour of hair, and the change of organization which accompanies it, but have not ſucceeded in ſatisfying ourſelves as to ſome points. In almoſt all the ſpecimens we have examined of human hair, during the proceſs of becoming grey, we have found the loſs of colour to commence at the point, and gradually to advance towards the root. In a few inſtances we have obſerved ſhort portions of the hair grey in the middle; and we have ſeen the hairs of the mane and tail of horſes becoming white at their roots; ſome hair-dreſſers alſo aſſert, that the hair of the human head occaſionally changes to grey firſt next the roots.

The term grey is not ſo proper as tranſparent would be, to hair that has undergone the change we ſpeak of, ſince it conſiſts not in an alteration of colour, but a total diſappearance of it, and which is not in the interior ſubſtance, as ſuppoſed by Bichat, but in the horny or external part of the hair. The ſilvery or gliſtening appearance of grey hair depends upon the light being refracted in paſſing through its tranſparent parietes, and ſtriking upon the cells of the pith in the interior.

It may be aſked, how is the colouring matter removed from the ſubſtance of the hair? There appears only two means by which it can be accompliſhed; it muſt either be diſſipated from the ſurface of the hair, or carried back into the ſyſtem by abſorption; the latter appears the moſt probable. If a hair become grey by the deſiccation or evaporation of any of its parts, the change would not be confined to particular portions of it, and the whole would afterwards appear withered or ſhrunk: weakly hairs, and thoſe which had their pulp obliterated, would likewiſe be the moſt apt to loſe their colour. The contrary of this, however, takes place. They are only permanent hairs that ever become grey. The ſtrongeſt and darkeſt coloured hairs are the moſt liable to the change, and afterwards generally appear to be ſtronger and thicker than before, and are longer in being ſhed than thoſe that have preſerved their colour. It may be added, that no means will have the effect of turning hairs grey, after they are removed from the body.

Many inſtances are recorded of the hair becoming ſuddenly grey before the uſual period, in conſequence of violent impreſſions made on the mind. The French revolution is ſaid to have furniſhed many examples of this kind. Bichat relates that he has known five or ſix caſes, in which the hair loſt its colour in leſs than eight days, and that he was acquainted with one perſon whoſe hair became almoſt entirely grey in the courſe of a ſingle night, in conſequence of hearing ſome diſtreſſing news. Climate has alſo a remarkable influence upon the colour of the hair, thus *hares*, *rabbits*, &c. have been known to become white during the winter, and to recover their natural colour again in the ſummer. Theſe facts leave no doubt with reſpect to the colour of the hair being changed by a vital operation. The growth of hair is abſolutely determined in ſome caſes by the evolution of other organs; thus the beard, the hair of the pubis, &c. depend upon the perfection of the organs of generation.

In the diſeaſe called plica polonica, the extraordinary magnitude of the hairs, and the hæmorrhage that follows cutting them,

them, ſhew an inordinate action in the blood-veſſels of the pulp, which probably, in this diſeaſe, paſſes much farther into the tube of the hair than uſual. The influence which this diſeaſe has upon the conſtitution, points out the propriety of taking into conſideration the effects the common growth of hair may have upon other organs. The practice of cutting the hair of the head and the beard is attended with a prodigious increaſe of the ſecretion of the matter of hair. It is aſcertained, that a man of fifty years of age will have cut from his head above thirteen feet or twice his own length of hair, and of his beard in the laſt twenty-five years of the ſame period, above eight feet. The hair likewiſe, beſides this enormous length, will be thicker than if it had been left uncut, and muſt loſe moſt of its juices by evaporation, from having its tube and the ends of its fibres always expoſed.

The cuſtom of ſhaving the beard and cutting the hair of the head, has, we believe, been juſtly deprecated by ſome phyſiologiſts. The latter has been ſuppoſed, and with much apparent reaſon, to weaken the underſtanding, by diverting the blood from the brain to the ſurface of the head. The connection which exiſts between the beard and the organs of generation, and likewiſe between it and the muſcular ſtrength of the individual, would ſeem to render it improper to interfere with its natural mode of growth. Bichat attributes the ſuperior ſtrength of the ancients to their cuſtom of wearing their beards; and thoſe men who do not ſhave at preſent are diſtinguiſhed for rigour and hardihood. They are likewiſe reputed to have ſuperior capacity for venereal enjoyments. The extirpation of the beard by the North American Indians, as having the oppoſite effect to ſhaving, may contribute to the well-known ſtrength of theſe people.

The re-production of hairs, when they are either ſpontaneouſly caſt or loſt by accident, reſembles in ſome degree that of teeth; the pulp which ſuſtained the old hair degenerates, and is abſorbed; while another pulp has formed beſide it, on which the new hair is produced: this operation is carried on in the cavity of the bulb, which undergoes no change.

In the plate for exemplifying the ſtructure and growth of hairs, horns, and ſpines, *fig.* 1. ſhews the natural ſize of a hair of the human head, with the bulbous capſule in which the root is incloſed. *Fig.* 2. is the bulb of the *ſeal's* whiſker unopened, and ſome of the large nerves which go to it; *a* the bulb, *b* the nerve. *Fig.* 3. repreſents the bulb of the whiſker of the *ſeal* deſpoiled of its external tunic; *a*, the ſpongy inveſtment; *b*, trunk of the nerve of the whiſker; *c*, the branches of the nerve traced into the ſpongy inveſtment. *Fig.* 4. is a longitudinal ſection of the pulp of the ſeal's whiſker, expoſing all its parts and the pulp; *a*, the external inveſtment; *b*, the ſpongy envelope; *c*, the internal tunic of the bulb; *d*, the pulp. *Fig.* 5. gives a magnified view of the root of a whiſker of the ſeal laid open; *a*, the pulp; *b*, the ſubſtance of the hair. *Fig.* 6. is an enlarged view of a longitudinal ſection of the whiſker of the ſeal; *a*, the root; *b*, the tube from whence the pulp had been removed; *c*, the remaining portion of the tube filled with pith. *Fig.* 7. ſhews a briſtle of a hog; *a*, the bulbous ſolid root, formed in conſequence of the pulp degenerating, before the whiſker is caſt. *Fig.* 8. exhibits an old hair about to be ſhed, and a young one coming forward to ſupply its place, and growing in the ſame bulb

For the further account of the hair-like productions of the body of mammalia, ſee SPINES and SCALES.

The waſte or refuſe *hair* of different ſorts of animals has been found to be highly beneficial as a manure where they can be procured in ſufficient quantity, ſuch as that of hogs and various other ſorts of quadrupeds.

HAIR, *diſeaſes of*, &c. &c. Among the many remedies for diſeaſes of the hair, the following are recommended in the Philoſophical Tranſactions. To make hair grow, take a quantity of the largeſt and fineſt roots of the common burdock that can be collected; let them he taken out of the ground in the month of December; bruiſe them in a marble mortar, and boil them in a quantity of white wine till there only remains as much as will cover them; let this be carefully ſtrained off, and every night, going to bed, let the head be waſhed with ſome of it warm. The other preſcription is this: burn the ſlender twigs of vines to aſhes, and boil theſe aſhes in ſuch a quantity of common water as will make a ſtrong lye; let this be ſtrained clear off, and the head waſhed every night with ſome of it warm. When the hair is good, but in danger of falling off by degrees, the aſhes of the vine branches are to be boiled in red-wine inſtead of water, and this lye is to be uſed inſtead of the other. When the perſon wears powder, let ſome hermodactyls be reduced to fine flour and mixed with it: let this be the only powder uſed, and the liquor conſtantly applied in waſhing the head every night, and the falling of the hair will be wholly prevented. Phil. Tranſ. N° 288. p. 90.

Wulrerus, in Philoſophical Collections, gives an account of a woman, buried in Norimberg, whoſe grave being opened forty-three years after her death, there was hair found iſſuing out plentifully through the clefts of the coffin; inſomuch that there was reaſon to imagine, the coffin had ſome time been covered all over with hair. The cover being removed, the whole corpſe appeared in its perfect ſhape; but from the crown of the head to the ſole of the foot covered over with a thick-ſet hair, long and curled. The ſexton going to handle the upper part of the head with his fingers, the whole ſtructure fell at once, leaving nothing in his hand but a handful of hair: there was neither ſkull, nor any other bone left; yet the hair was ſolid, and ſtrong enough.

Mr. Arnold, in the ſame Collections, gives a relation of a man hanged for theft, who, in a little time, when he yet hung upon the gibbet, had his body ſtrangely covered over with hair.

It was eſteemed a peculiar honour among the ancient Gauls, to have long hair; and hence came the appellation *Gallia comata*. For this reaſon Julius Cæſar, upon ſubduing the Gauls, made them cut off their hair, as a token of ſubmiſſion. It was with a view to this, that ſuch as afterwards quitted the world, to go and live in cloiſters, procured their hair to be ſhaven off; to ſhew that they bid adieu to all earthly ornaments, and made a vow of perpetual ſubjection to their ſuperiors.

Greg. de Tours aſſures us, that, in the royal family of France, it was a long time the peculiar mark and privilege of king's and princes of the blood, to wear long hair, artfully dreſſed and curled: every body elſe were obliged to be polled, or cut round, in ſign of inferiority and obedience. Some writers aſſure us, that there were once different cuts of the hair for all the different qualities and conditions; from the prince, who wore it at full length, to the ſlave or villain, who was quite cropt. Hottoman treats at large of this privilege of the kings of France, Franco Gallia. cap. 11.

The cut of the hair of a ſon of France, under the firſt race of kings, was to declare him excluded from the right of ſucceeding to the crown, and reduced to the condition of a ſubject.

In the eighth century it was the cuſtom of people of quality, to have their children's hair cut the firſt time by perſons

perſons they had a particular honour and eſteem for; who, in virtue of this ceremony, were reputed a ſort of ſpiritual parents, or godfathers to them; though this practice appears to have been more ancient; inaſmuch as we read that Conſtantine ſent the pope the hair of his ſon Heraclius, as a token that he deſired him to be his adoptive father.

The parade of long hair became ſtill more and more obnoxious in the progreſs of Chriſtianity; as ſomething utterly inconſiſtent with the profeſſion of perſons who bore the croſs. Hence numerous injunctions and canons to the contrary. Pope Anicetus is commonly ſuppoſed to have been the firſt who forbad the clergy to wear long hair; but the prohibition is of older ſtanding in the churches of the Eaſt; and the letter wherein that decree is wrote, is of a much later date than that pope. The clerical tonſure is related, by Iſidore Hiſpalenſis, as of apoſtolical inſtitution.

Long hair was anciently held ſo odious, that there is a canon ſtill extant, of the year 1096, importing, that ſuch as wore long hair ſhould be excluded coming into church when living, and not be prayed for when dead.

We have a furious declamation of Luitprand againſt the emperor Phocas, for wearing long hair, after the manner of all the other emperors of the Eaſt, except Theophilus; who, being bald, enjoined all his ſubjects to ſhave their heads.

The French hiſtorians and antiquaries have been very exact in recording the heads of hair of their ſeveral kings. Charlemagne wore it very ſhort, his ſon ſhorter; Charles the Bald had none at all. Under Hugh Capet it began to appear again: this the eccleſiaſtics were diſpleaſed with, and excommunicated all who let their hair grow. Peter Lombard expoſtulated the matter ſo warmly with Charles the Young, that he cut off his own hair; and his ſucceſſors, for ſome generations, wore it very ſhort. A profeſſor of Utrecht, in 1650, wrote expreſsly on the queſtion, Whether it be lawful for men to wear long hair? And concluded for the negative. Another divine, named Reeves, who had wrote for the affirmative, replied to him.

The Greeks, and after their example, the Romans, wore falſe hair.

The cutting off the hair in mourning for the dead is an Eaſtern, as well as a Grecian cuſtom; and appears to have obtained in ancient times, as well as in later ages. Among the ancient Greeks, it was ſometimes laid upon the dead body, ſometimes caſt into the funeral pile, and ſometimes placed upon the grave. How the Jews diſpoſed of it we are not told; but that they cut it off we are aſſured. See Jer. xvi. 6. For other particulars, ſee BEARD.

HAIR makes a very conſiderable article in commerce; eſpecially ſince the mode of perukes has obtained: though among gentlemen this faſhion has of late very much ſubſided. But they were never more common among the fair ſex than at preſent.

The hair of the growth of the northern countries, as England, &c. is valued much beyond that of the more ſouthern ones; as Italy, Spain, the ſouth parts of France, &c.

The excellence of good hair conſiſts in its being well fed, and neither too coarſe nor too ſlender; the bigneſs rendering it leſs ſuſceptible of the artificial curl, and diſpoſing it rather to frizzle; and the ſmallneſs making its curl of too ſhort duration. Its length ſhould be about twenty-five inches; the more it falls ſhort of this, the leſs value it bears.

There is no certain price for hair; but it is ſold from five ſhillings to five pounds an ounce, according to its quality.

The ſcarceneſs of grey and white hair has put the dealers in that commodity upon the methods of reducing other colours to this. This is done by ſpreading the hair to bleach on the graſs like linen; after firſt waſhing it out in a lixivious water.

This lye, with the force of the ſun and air, brings the hair to ſo perfect a whiteneſs, that the moſt experienced perſon may be deceived therein; there being ſcarce any way of detecting the artifice, but by boiling and drying it, which leaves the hair of the colour of a dead walnut-tree leaf.

There is alſo a method of dyeing hair with biſmuth; which renders ſuch white hair as borders too much upon the yellow, of a bright ſilver colour; boiling is the proof of this too, the biſmuth not being able to ſtand it.

Hair, made perfectly clean, and moiſtened with the ſolution of ſilver in aqua fortis, expoſing it to the ſun, in order to haſten the appearance and deepen the colour, will be changed from red, grey, or other diſagreeable colours, to a brown or deep black. The ſolution for this purpoſe ſhould be fully ſaturated with the ſilver, diluted only with diſtilled water or pure rain water; and for the farther dulcification of the acid, it will be proper to add a little rectified ſpirits of wine. The liquids commonly ſold under the name of hair-waters, are in reality no more than ſolutions of ſilver, much diluted with water.

Hair which does not curl or buckle naturally, is brought to it by art; by firſt boiling, and then baking it in the following manner: after having picked and ſorted the hair, and diſpoſed it in parcels, according to lengths, they roll them up, and tie them tight down, upon little cylindrical inſtruments, either of wood or earthen ware, a quarter of an inch thick, and hollowed a little in the middle, called pipes; in which ſtate they are put in a pot over the fire, there to boil for about two hours. When taken out, they let them dry; and when dried, they ſpread them on a ſheet of brown paper, cover them with another, and thus ſend them to the paſtry-cook; who making a cruſt, or coffin, around them of common paſte, ſets them in an oven, till the cruſt is about three-fourths baked.

The end by which a hair grew to the head, is called the *head* of the hair; and the other, with which they begin to give the buckle, the *point*. Formerly the peruke-makers made no difference between the ends, but curled and wove them by either indifferently; but this made them unable to give a fine buckle; hair woven by the point never taking a right curl. Foreigners own themſelves obliged to the Engliſh for this diſcovery, which was firſt carried abroad by a peruke-maker of our country.

HAIR is alſo uſed in divers arts and manufactures.

The hair of beavers, hares, conies, &c. is the principal matter whereof hats are made.

Spread on the ground, and left to putrefy on corn-lands, hair, as all other animal ſubſtances, *viz.* horns, hoofs, blood, garbage, &c. proves good manure.

Hair alſo makes an ingredient in the compoſition of plaſter.

The hair of goats is uſed for the manufacture of fine ſtuffs and ſhawls in various parts of the Eaſt. (See ANGORA, ALEPPO, CASHEMIRE, &c.) Camels have alſo in ſome places yielded hair as fine as ſilk, and it has been employed in the manufacture of ſtuffs and ſhawls; though in general their hair is hard, and fit only for coarſe garments, and a kind of hair-cloths. Ælian relates (Hiſt. Anim. l. xvii. c. 34.) that there were camels on the Caſpian ſea whoſe wool was as fine as that of Miletus, and that the prieſts and richeſt people of the country wore the ſtuffs which were made of it. See CAMBLET and CAMEL.

HAIR,

Hair, in the *Manège*, and among *Farriers*, is popularly called the *coat*, and makes an object of principal consideration in respect of horses, &c.

If the hair of a horse, especially that about the neck, and parts uncovered, be sleek and smooth, and close, it is an indication of his being in health, and good case: if rough and staring, or any way discoloured, it denotes a coldness, poverty, or some inward defect. To make the hair smooth, sleek, and soft, he must be kept warm, sweated often, and when sweated, the coat must be well scraped, and rubbed down.

The hair growing on the fetlock, serves as a defence to the prominent parts thereof, in travelling on stony ways or in frosty weather.

If a place be bare, or thin of hair, or the hair be too short, the ancient farriers used to wash it with the urine of a young boy: and after that with the lye of unslaked lime, ceruse, and litharge. The moderns have various other ways: some wash the part with the decoction of the roots of althæa; others with goat's milk, wherein agrimony has been pounded; others rub the part with nettle-seed, bruised with honey-water and salt; others anoint it with the juice of an onion, or radish; others with a mixture of alum, honey, goat's dung, and swine's blood; others with the root of white lily, boiled in oil; others with tar, oil of olives, and honey; and others with green walnut-shells, powdered, and mixed with honey, oil, and wine. To take off hair in any part, they apply a plaster made of unslaked lime, boiled in water, with orpiment added.

Hair *balls*, masses of hair of different shapes and sizes found in the stomachs of cows, oxen, calves, deer, and other animals. See Ægagropila, Balls, in *Zoology*, and Bezoar.

Hair-*bell*, in *Botany*. See Hyacinth.

Hair, *capillus*, is the first degree of the Linnæan scale for measuring plants, or the twelfth part of a line.

Hair-*cloths*, in *Military Affairs*, are large pieces of cloth made with half hair; they are used for covering the powder in waggons, or upon batteries; as also for covering charged bombs, or hand-grenades, and many other uses in magazines.

Hair-*grass*, in *Rural Economy*, the name of a coarse sort of grass, of which there are several species, but which are very little used as cultivated grasses, though some of them are eaten by cattle, and some other sorts of live stock. See Aira.

Hair, *Maiden*, in *Botany*. See Adiantum.

Hair *Powder*. See Starch.

Hair-*staring*, in *Rural Economy*, a certain state or condition in the coats of horses or other animals, in which they appear rough and stand in an erect sort of position.

It is produced by various causes, such as want of proper food, bad currying, and their not being covered sufficiently, or kept in too cold stables or other places.

In order to preserve the coats of these animals in a fine sleek condition, it is necessary that they be kept perfectly well, and sufficiently warm, having constantly good grooming in the stables while they are in work. By these means they generally soon become better coated and more sleek.

Hairs of *Plants*, in *Vegetable Physiology*, are so called rather from a general resemblance to those of animals, than from any precise agreement in their structure or mode of production. In their uses they are so far similar, that, forming a covering which is a bad conductor of heat, they serve to guard the vegetable body from the immoderate influence of external cold as well as heat; yet they are very frequently, and indeed most commonly, so thinly scattered, as to be of very little use in this way, and must doubtless answer other purposes. It is generally to be remarked that hairiness is more abundant on the backs or under sides of leaves, than on the upper, though the latter is most exposed both to heat and cold; but this is only while the leaves are full grown and employed in their most important functions. In a young and unexpanded state, the hairy covering of their backs and ribs, at that time most exposed, may be of eminent service, and there can be no doubt that the pubescence, with which buds of various kinds are often assiduously clothed and protected, may very materially guard their living principle and latent warmth from external injury.

Linnæus defines the hairs of plants to be excretory ducts of a bristle-like form. Such they are in the nettle, and other stinging vegetables of the same nature, whose bristles are tubular and pervious, emitting a venomous fluid into the minute wounds their points inflict, as is well explained by Mr. Curtis in his *Flora Londinensis*, under *Urtica dioica*, fasc. 6. t. 69. "The naked eye," says that ingenious author, "readily perceives the instruments by which the nettle instils its poison; a microscope of no great magnifying power more plainly discovers them to be rigid, transparent, tubular *setæ*, prickles, or stings, highly polished and exquisitely pointed, furnished at their base with a kind of bulb, in which the juice is principally contained, and which being pressed on when the sting enters the skin, forces the poison into the wound. Of the venomous quality of this liquid, and of the manner in which it is emitted, I have had ocular proof. Placing the footstalk of a nettle leaf, *Urtica pilulifera* (the prickles being more manageable, and better adapted to the microscope, than those on the leaves or stalks), on the stage of the microscope, so that the whole of the prickle was in the focus when horizontally extended, I pressed on the bulb with a blunt-pointed pin, and, after some trials, found a liquid to ascend in the prickle, somewhat as the quicksilver does when a warm hand is applied to the bulb of a thermometer. In some of the prickles I observed the liquid stationary. On pressing such in particular, I saw most plainly the liquor ascend to, and flow copiously from, its very extremity. I was the more anxious to see this, as I suspected the poison might proceed from an aperture in the side of the sting, near the point, as in the forceps of the spider and tooth of the viper, where it appears to be placed, rather than at the extremity, that it may not take off from their necessary sharpness. Pricking the skin of my hand with a needle, I placed some of the juice on the wound, which instantly inflamed, and put on all the appearance of a part stung by a nettle."

The cultivated Clary, *Salvia sclarea*, like a multitude of other plants, is clothed with soft hairs, whose points exude a viscid, and, in many instances, highly aromatic fluid. In such the excretion is doubtless similar to that of the nettle, varying only in proportion according to the health of the plant, warmth of the atmosphere, or other causes. There is probably in these no particular reservoir, to retain the liquor for occasional emission, as in the nettle; and yet perhaps the fragrance of some plants in the cool of the evening, which have exhaled no scent during the day, may be explained on a similar principle. It is not absurd to suppose that their aromatic secretions, elaborated in the heat of the day, may be lodged in their tubular pubescence, till forced out by the contracting power of the cold on its fine membranous substance.

The hairs which clothe many plants, however, neither ecrete nor discharge any fluids, or, at most, only while the parts they cover are very young and tender. In such they

can be conſidered merely as a defence againſt cold, heat, or inſects. Sometimes each particular hair is hooked, barbed, branched, forked, or ſtellated, and the whole are entangled or matted together, as in *Verbaſcum*. A ſtarry pubeſcence is often characteriſtic of a natural family of plants, as the *Columniferæ*, or Mallow tribe; while in others, as the genus *Ciſtus*, it ſerves at moſt but to mark a ſpecific difference. Forked hairs are not conſtant, even in the ſame ſpecies, in all circumſtances; witneſs *Hedypnois*. Rich nouriſhment, or much ſhade or ſhelter, have all a tendency to ſimplify, and partly to efface the pubeſcence of plants; while expoſure, and every thing that cauſes condenſation, or contraction of parts, multiplies and augments it.

It is difficult to account for the finely jointed ſtructure ſo general in the hairs of plants; nor can it be ſuppoſed that any fluid can paſs through ſuch, their tube being intercepted by ſeveral tranſverſe partitions. This kind of hairs, therefore, cannot be excretory ducts, and yet they belong to aromatic plants, as the *Didynamia Gymnoſpermia* of Linnæus, amongſt others. They are beſt ſeen in dried ſpecimens. Some ſpecies of *Begonia*, and a few ferns, bear flat ſtrap-like hairs, or more properly *ramenta*, ſhavings, which are commonly diſtant, but otherwiſe not different in nature from the cylindrical pubeſcence. The pubeſcence of many of the *Aſperifoliæ*, a tribe conſiſting of *Echium*, *Borago*, &c. is a beautiful and curious microſcopic object, each rigid poliſhed briſtle ſpringing from a knob or tubercle reſembling wrought ivory, of whoſe uſe we are ignorant. It is ſituated in the place of the bag of poiſon ſeen in the nettle; but the *aſperifoliæ*, though they often wound ſharply, do not ſting.

The pubeſcence of plants being, as we have ſaid, liable to vary in ſtructure and in degree, according to adventitious circumſtances, does therefore not, in thoſe reſpects, prove an infallible guide to ſpecific diſtinctions. Its direction, however, is found ſubject to no ſuch uncertainty, and has been made uſe of by the writer of this article in the genus *Mentha*, and by Dr. Roth in that of *Myoſotis*, to diſcriminate ſpecies not to be defined by any other means, but which, however they may vary in every other reſpect, are found conſtant in the direction of the hairs of their flower-ſtalks and calyx. In the intricate genus of *Galium* alſo, the ſame character ſerves us very unexceptionably in the briſtles of the ſurfaces or edges of their leaves. Jacquin has had recourſe to it; and we have followed him, in the fringes of the leaves, in ſome kinds of *Hæmanthus*. It is attended to with advantage on the ſtems of graſſes, as *Bromus*, and on thoſe of *Papaver pilоſum*, Prod. Fl. Græc. n. 1202, contraſted with *P. orientale*. Doubtleſs, however, even this mark, like every other, muſt be employed with diſcretion; for the hairs of ſome plants, though erect in the living or freſh ſubject, will be found regularly depreſſed by drying. S.

Hair's *Breadth*. This is accounted the forty-eighth part of an inch.

HAIRHOUGH, a name commonly applied to cleavers.

HAIRIT, a term ſometimes provincially made uſe of to ſignify cleavers.

HAIRY Roots. See Fibrous *Roots*.

HAI-TAN-CHING, in *Geography*, a ſmall iſland near the coaſt of China, about 24 miles long, and 3 broad. N. lat. 25 35'. E long. 119 39'.

HAI-TIEN, a town of China, in the province of Pe-che-li, a little N.W. of Peking.

HAI-YEN, a town of China, of the third rank, in the province of Tche-kiang; 20 miles S.S.E. of Kia-hing.

HAJYGUNGE, a town of Hindooſtan, in Oude, on the Goomty; 40 miles N. of Manickpour.—Alſo, a town of Bengal; 38 miles S. of Dacca.

HAJYKAN. See Sindy.

HAJYPOUR, a circar of Hindooſtan, in Bahar, bounded on the N. by Bettiah, on the N.E. by Tyroot, on the E. by Boglipour, on the S. by the Ganges, which ſeparates it from Bahar Proper, and on the W. by the circar of Sarun; about 100 miles long, and from 20 to 30 broad. Its capital, of the ſame name, is ſituated on the left bank of the Ganges, oppoſite to Patna.—Alſo, a town of Hindooſtan, in Mewat; 15 miles N. of Cotputly.—Alſo, a town of Hindooſtan, in Guzerat; 40 miles W. of Ahmedabad.

HAKAS, a town of Sweden, in the province of Jamtland; 20 miles S. of Froſon.

HAKE, in *Ichthyology*, the common Engliſh name of Gadus *Merlucius*; which ſee.

This fiſh was uſed of old, dried and ſalted. Hence the proverb obtains in Kent, *as dry as a hake*. Paroch. Antiq. 575.

Hake, *Forked*, a trivial Engliſh name for the Linnæan *Blennius phycis*. See Phycis.

HAKEA, in *Botany*, ſo named by profeſſor Schrader, in compliment to baron Hake, a patron of the botanic garden at Hanover; ſee Conchium. We have preſumed to retain the latter name, chiefly becauſe of its peculiar aptitude for the genus in queſtion, which is ſo great, as to be rarely equalled in ſcientific nomenclature, and it is much to be lamented that ſuch a name ſhould be ſuperſeded, though *Hakea* was printed, unknown to the author of *Conchium*, a few months before. To this preference of the latter, Ventenat, the younger Gærtner, and even Cavanilles, juſt before his death, aſſented; without any prejudice to the honours of baron Hake, for whom another genus might eaſily be ſelected out of many leſs worthily beſtowed. Above all, we diſclaim all intention of diſreſpect to the authority of the learned and amiable Schrader, which is of the firſt rank, and reverenced by no one more than ourſelves. Botanical nomenclature will never retain any ſhadow of claſſical excellence or purity, unleſs ſome ſenſe, judgment, and taſte be allowed now and then to take place of mere blind dictatorial authority of any kind; and it is the duty of thoſe, who have talents and power ſufficient, to cultivate and protect its advancement towards perfection. In this cauſe the great Linnæus long ſtruggled with barbariſm, and with barbarians, who, becauſe they could not eclipſe his fame, laboured to undermine his authority, careleſs whether the intereſts of ſcience ſuffered by it or not. If he at laſt occaſionally fainted in the conteſt, his followers ſhould copy his beſt efforts, not meanly ſubmit, becauſe he through inadvertence now and then made a falſe ſtep. S.

HAKEL, or Hatchel. See Hatchel.

Hakel, in *Geography*, a town of Arabia Felix, in the province of Yemen; 40 miles S.S.E. of Abu-Ariſch.

HAKELSDORF, a town of Bohemia, in the circle of Konigingratz; 16 miles N.N.E. of Gitſchin.

HAKEM-BAMRILLAH, in *Biography*, the third of the Fatemite caliphs of Egypt, who ſucceeded to the throne in the year 996, at the age of eleven. Having been brought up without the neceſſary reſtraints impoſed by a good education, he was frantic with the power devolved upon him, and ſeemed equally regardleſs of God or man, and his whole reign was a wild mixture of vice and folly. Without attending to the ancient cuſtoms of Egypt he impoſed on the women an abſolute confinement, forbidding them, upon the ſevereſt penalties, the uſe of ſhoes, and prohibiting any perſons from manufacturing them as articles of dreſs. This reſtraint excited furious clamours from both ſexes, but their complaints provoked his fury, and he deſtroyed the great part of the capital,

Cairo,

Cairo, by fire, and delivered the reſt to pillage, which cauſed the moſt bloody conteſts between the ſoldiery and thoſe inhabitants, who preferred death to the quiet reſignation of their property. At one time he affected a profound reverence for the Mahometan religion, and became the founder of moſques and colleges. He had upwards of twelve hundred copies of the Koran tranſcribed at his own expence in letters of gold, and he rooted up all the vines of Upper Egypt, in order to prevent the manufacture of wine, the uſe of which was prohibited by the prophet. His vanity ſoon induced him to aſpire to ſtill higher honours: he ſtyled himſelf the viſible image of the true God upon earth, claimed the honours of adoration to his perſon, and cauſed the myſteries of his worſhip to be performed on a mountain near Cairo. When kings and emperors become prophets, there is no fear but flatterers and fools will ſoon be converted to the faith promulgated from the royal throne; accordingly ſixteen thouſand perſons very ſoon ſanctioned, by their practices, the abſurdities of Hakem: but what is more extraordinary is this, that the Druſes of Mount Libanus, even at the preſent day, retain a perſuaſion of the divinity and exiſtence of the caliph, or, as they denominate him, the prophet Hakem. Under the maſk of a new religion, he perſecuted Jews and Chriſtians wherever his power extended. But in Egypt and Paleſtine his cruel and wanton conduct made martyrs of ſome believers, and apoſtates of others: the common rights and privileges of all who would not follow him in his abſurdities were equally diſregarded. He demoliſhed the church of the reſurrection at Jeruſalem, to its very foundations. After this he pretended ſome compunctions of conſcience, and ordered the reſtitution of the churches; but the people knowing that no dependence could be placed on his meaſures, when founded in juſtice, and being unable longer to endure his tyranny, put an end to his life and reign, by a conſpiracy, at the head of which was his own ſiſter. Gibbon.

HAKES, in *Agriculture*, a term ſometimes provincially applied to the copſe, or draught-iron of a plough.

HAKETON, in our *Old Writers*, a military coat of defence.

HAKEWELL, George, in *Biography*, was born at Exeter in the year 1579. Having laid a good foundation in elementary learning, he went firſt to St. Alban's hall college, Oxford, and then to Exeter college to purſue his ſtudies. At the latter he was elected fellow, and having taken his degrees, and being admitted to orders, he went abroad for farther improvement. In 1611, he took his degree of D.D., and was ſoon after appointed chaplain to prince Charles, which led to preferment in the church. When, however, a marriage was projected between his pupil and the infanta of Spain, he wrote a treatiſe againſt the intended union, which he ſhewed the prince in manuſcript, under the ſtrict injunction that it ſhould meet no other eye; the honour of a prince was not very binding, for in two hours he delivered it into the hands of his father, who inſtantly ordered the author to be taken into cuſtody. The impriſonment was of ſhort duration; but the tutor was never reſtored to his ſituation, nor to the king's favour. The high men of this world rarely forgive, and James was too lofty to make an exception to the general rule. Under the reign of Charles, he was promoted to the biſhopric of Worceſter, and elected rector of Exeter college. Upon the breaking out of the civil wars he ſubmitted to the authority of parliament, and retained his office as rector of the college till his death, in 1649. He was a great divine, a good philoſopher, and a celebrated preacher. As an author, his chief work was entitled "An Apology, or Declaration of the Power and Providence of God in the Government of the World, proving it doth not decay," folio: he publiſhed, likewiſe, twelve ſermons on David's vow to reform himſelf, his family, and his kingdom: "A Treatiſe on Confirmation," and many ſingle ſermons, and controverſial tracts. Biog. Brit. Toulmin's Edit. of Neale's Hiſt. of the Puritans.

HAKIAR, in *Geography*, a town of Curdiſtan; 20 miles N.E. of Gulamerik.—Alſo, a river of the ſame country, which runs into the Zab; 20 miles W. of Erbil.

HAKIMPOUR, a town of Bengal; 11 miles E.N.E. of Mahmudpour.

HAKLUYT, Richard, in *Biography*, was born in or near London about the year 1553. He was educated at Weſtminſter ſchool, and, being accuſtomed to viſit an uncle greatly attached to maritime purſuits, he acquired a taſte for geographical and naval enquiries, which at length became his ruling paſſion. During his ſtudies at Oxford, he rendered himſelf ſo conſpicuous by his vaſt knowledge on theſe kinds of ſubjects, that he was appointed to read public lectures upon coſmography and the ſciences connected with it. Of the particular plan of this courſe of lectures we have no account: of its utility and excellence there can be no doubt, ſince ſir Francis Drake not only acknowledged great obligations to it, but was deſirous of eſtabliſhing a lecture on navigation at Oxford. In 1582 Mr. Hakluyt publiſhed a ſmall "Collection of Voyages and Diſcoveries," which procured him a commiſſion from the ſecretary of ſtate to confer with ſome merchants of Briſtol reſpecting an expedition to Newfoundland and the adjacent parts. He next engaged as chaplain to ſir Edward Stafford, in an embaſſy to France, where he remained five years. Here he cultivated an acquaintance with all perſons eminent for the branches of ſcience to which he had attached himſelf, and procured a French account of Florida, which he tranſlated into Engliſh, and dedicated to ſir Walter Raleigh. He cauſed to be tranſlated into his native language, an improved edition of Peter Martyr's work "De Orbe novo," under the title of "The Hiſtory of the Weſt Indies," by Mr. Lock. Upon his return from the continent in 1588, he was nominated by ſir Walter Raleigh one of the corporation of adventurers, to whom he aſſigned his patent for the proſecution of diſcoveries in America. He immediately ſet about the collection and arrangement of all the accounts and documents of voyages by Engliſh navigators, and in the following year he publiſhed, in one volome folio, "The principal Navigations, Voyages, and Diſcoveries of the Engliſh Nation, made within theſe Fifteen hundred Years." This collection, which was augmented by two other volumes, contains the narratives of more than two hundred voyages, and is reckoned a highly valuable treaſury of facts. The laſt volume was publiſhed in the year 1600. In 1601 he publiſhed a tranſlation from the Portugueſe of "Antonio Galvano's Hiſtory of Diſcoveries," and in a few years after Ferdinand de Soto's "Deſcription of Florida." This was his laſt work: he died in the year 1616, and was buried in Weſtminſter Abbey. He had obtained preferment in the church, but to no great value. Biog. Brit.

HAKMAN, in *Geography*, a town of the iſland of Ceylon; 80 miles S. of Candy.

HAKSVIK, a town of Sweden, in the province of Weſt Gothland; 25 miles S. of Ulrichſhamn.

HAL, in *Entomology*, according to Dapper, the name by which the Africans diſtinguiſh the ſcorpion.

HALABOOR, in *Geography*, a town of Bootan; 58 miles N. of Dinagepour.

HALABI, one of the Kartan iſlands. See Kartan.

HALAVORD, a town of Perſia, in the province of Comis; 16 miles W. of Biſtain.

HALBARD, or HALBERT, in the *Art of War*, an offenſive weapon, conſiſting of a ſhaft, or ſtaff, five feet long; with a ſteel head, partly in form of a creſcent.

The word is formed of the German *hal*, *hall*; and *bard*, an *hatchet*. Voſſius derives it from the German *hallebaert*: of *hel*, *clarus*, *ſplendens*, and *baert*, ax.

The halbard was anciently a common weapon in the army; where there were companies of halberdeers. It is ſtill carried by the ſerjeants of foot.

It is called the Daniſh ax, becauſe firſt bore by the Danes: they carried it on the left ſhoulder. From the Danes it was derived to the Scots, and from the Scots to the Engliſh, and from them to the French.

HALBERSTADT, in *Geography*, a principality of Germany, extending from E. to W. about 36 miles, and 28 from N. to S. It is generally level, with ſome few hills. The ſoil is very fertile in grain and flax, and it has rich paſtures and meadows. Its large breeds of ſheep afford plenty of wool. Its coal pits are of no importance; and as their wood is diminiſhing, fuel is ſcarce; and as a ſubſtitute ſtraw and ſtubble are uſed. As it has no river of any conſiderable magnitude, fiſh is ſcarce. The inhabitants are moſtly Lutherans, diſtributed into 11 inſpections, under a general ſuperintendancy. The Calviniſts and Catholics are nearly equal in number. The Jews are tolerated within a certain number of families. The woollen manufactures thrive. By the treaty of Weſtphalia in 1648, this principality was transferred to the electoral houſe of Brandenburg; but by the late treaty of Tilſit, it was annexed to the kingdom of Weſtphalia.—Alſo, an ancient city of Weſtphalia of the ſame name, ſaid to have been built by the Cheruſci. The number of inhabitants is about 12,500; and the number of churches 16. The cathedral is an old but ſtately building, conſtructed of hard free-ſtone. The chapter is compoſed of a provoſt, dean, ſenior and ſubſenior, and 16 canons, four of whom are Catholics, the reſt Lutherans. The palace is converted into the town-houſe, toll, and exciſe offices. The increaſe of inhabitants has occaſioned the addition of three ſuburbs; 30 miles S.W. of Magdeburg. N. lat. 51° 54'. E. long. 11° 12'.

HALBERT, among *Farriers*, &c. is a piece of iron, an inch broad, and three or four inches long, ſoldered to the toe of a horſe's ſhoe, that jets out before; to hinder a lame horſe from reſting or treading upon his toe.

Halbert-ſhoes of neceſſity conſtrain a lame horſe to tread, or reſt on his heel, when he goes a moderate pace; which lengthens and draws out his back ſinew, that was ſomewhat ſhrunk before. Theſe halbert-ſhoes are uſually injurious.

HALCRYPTIUM, a name given by Dr. Hill to a peculiar ſalt diſcovered in the chalybeate waters, and mentioned by Hoffman and ſome other authors, though not before known by any peculiar name.

The word is derived from ἅλς, *ſalt*, and κρυπτω, *to hide*, it being the moſt latent, and with the greateſt difficulty diſcoverable or ſeparable, of the native ſalts. It is defined to be a ſalt found naturally in a fluid form, ſuſpended in ſmall quantities in certain waters, ſcarce diſcernible in them by its taſte, and very difficultly ſeparable from them; but by a proper evaporation to be procured in a dry form in extremely ſmall particles, in form of powder; which, when carefully prepared by a proper ſolution and evaporation, affords extremely minute, oblong, and quadrangular cryſtals. Hill, Hiſt. of Foſſ. p. 397.

The chalybeate waters all afford this ſalt in ſome degree, but none ſo plentifully as the Pyrmont.

This ſalt ſeems of the utmoſt importance to the water, in which it is contained, ſince it can be ſuppoſed to contain no other alkali, and without an alkali it is not eaſy to account for its properties; to which it may be added, that, by means of the common alkali of tartar, and a ſolution of the pyrites, or even of iron, in an acid mixed with common water, a liquor may be made, very much reſembling the natural Pyrmont water.

HALCYON, or KING-FISHER, in *Ornithology*. See ALCEDO.

HALCYON-*days*, *dies alcyonii*, a phraſe that frequently occurs among writers, to denote a time of peace and tranquillity.

The expreſſion takes its riſe from a ſea-fowl, called, among naturaliſts, *halcyon*, or *alcyon*, which is ſaid to build its neſt about the winter ſolſtice, when the weather is uſually obſerved to be ſtill and calm. See ALCEDO.

Halcyon-days, according to ancient tradition, are the ſeven days before, and as many after the brumal ſolſtice; called alſo *St. Martin's Summer*: theſe are famous for the calmneſs of the weather, which emboldens the halcyon to build, and brood its eggs on the rocks, on the very brink of the ſea.

Columella gives the denomination, *halcyonii dies*, to a number of days commencing on the eighth of the calends of March; on account of the great ſtillneſs of the Atlantic ocean, then uſually obſerved.

HALCZIN, in *Geography*, a town of Poland, in the palatinate of Braclaw; 20 miles E.S.E. of Braclaw.

HALDE, JOHN BAPTIST DU, in *Biography*, was born at Paris in the year 1674, was early initiated into the ſociety of the Jeſuits, and was entruſted with the care of collecting and arranging the letters ſent by the ſociety's miſſionaries into different parts of the world. Little is known of his hiſtory, except as it is connected with his works. He was ſecretary to father Le Tellier, the king's confeſſor. His great work was "Deſcription hiſtorique, geographique, et phyſique de l'Empire de la Chine, et de la Tartarie Chinoiſe," four vols. fol. This is eſteemed the moſt complete account of that vaſt empire that has ever appeared in Europe. We are well aware of the works of ſir George Staunton and Barrow, but they never were in poſſeſſion of the means of information which occurred to Du Halde. It has been tranſlated into our own language, but in an abridged ſtate. He died in the year 1743, leaving behind him a character eminent for mildneſs, piety, and unwearied induſtry. He was author of ſome Latin poems; and was diſtinguiſhed as the editor of the "Lettres Edifiantes," with a preface written by himſelf. Moreri.

In our article on CHINESE *Muſic*, drawn up from the moſt recent and authentic information, it will appear that the accounts which this learned and pious miſſionary has given of the muſic of this ancient and extenſive empire, is confirmed in almoſt every important circumſtance. See CHINESE *Muſic*.

HALDENSTEIN, in *Geography*, a barony of the Grisons in Switzerland, near Coire, which, as Mr. Coxe ſays, is the ſmalleſt ſovereignty in Europe. It was formerly under the protection of the ſeven ancient cantons of Switzerland, but ſince the year 1568, it has been an independent ſovereignty, under the protection of the three leagues. The whole barony conſiſts of a ſemicircular plain, between the Rhine and the bottom of the Calendar, about five miles in length, and ſcarcely one in breadth; and alſo occupies part of the mountain, which is too ſteep to be inhabited. It contains only two villages, Haldenſtein and Sewils, and the ſubjects amount to no more than between three and four hundred. The people were ſerfs, or vaſſals, until 1701, when they obtained

tained feveral immunities. At preſent, or at leaſt before the French revolution, the lord has territorial juriſdiction, the excluſive privilege of hunting and fiſhing, a claim of two days' work annually from each of his ſubjects, and a load of dung from each peaſant. He appoints the judge in the criminal court, receives the fines for offences, from which he pays the expences of the proceſs, and has the power of pardoning. He nominates the preſident, and part of the jury in civil cauſes, and in all caſes of appeal, judges in the laſt reſort.

HALDESLEBEN, a town of Weſtphalia, in the duchy of Magdeburg; 12 miles N. of Magdeburg. N. lat. 52° 20'. E. long. 11° 34'.

HALDIMAN Township, a townſhip of Northumberland county, Upper Canada, to the W. of Cramake, and lake Ontario.

HALE, *Sir* Matthew, in *Biography*, a moſt eminent lawyer, was born in 1609 at Alderſley, in Glouceſterſhire. He was educated under a Puritanical clergyman; but in the early part of life he was not free from thoſe levities which uſually attach to youth, and his diſpoſition ſeemed rather for martial than literary exerciſes. It was not till he had arrived at the age of manhood, that he could be prevailed on to enter his name at Lincoln's Inn, but from this moment he ſeemed deſirous of redeeming his time, and bent the whole force of his genius to the profeſſion in which he had engaged. He is ſaid to have ſpent ſixteen hours a day in ſtudy for ſeveral years; he was, in truth, perfectly changed, became ſerious and devout, and omitted no opportunity of performing thoſe religious duties which become the creature to obſerve, in teſtimony of his dependence on the creator. The life he now led was entirely that of a recluſe, and he dedicated no hours to conviviality or even ſocial intercourſe. He did not content himſelf with the ſtudy of the law; he extended his inquiries to almoſt every object of human learning, and became well verſed in mathematics, philoſophy, hiſtory, and the theology of the age. He was called to the bar ſome time before the breaking out of the civil war, and when that unfortunate event occurred, he took the moſt honourable and uſeful courſe, though perhaps not the moſt prudent, *viz.* that he would engage with no party, but that he would be ever ready to aſſiſt thoſe that were loweſt. With this reſolution he was counſel for ſeveral of the oppreſſed loyaliſts, and for the king himſelf; yet he did not ſcruple to take the covenant, and to act as a lawyer in the concerns of parliament. He had a high reputation for honour and integrity, and on that account ſtood well with all thoſe who were actuated by good motives of each party. He was perſuaded in 1654 to accept of the office of chief juſtice, in which elevated ſtation he maintained the dignity of the laws, and the rights of the people, with a ſpirit that was not very pleaſing to the protector, who told him on his return from the circuit, "that he was not fit for a judge." Hale, with much modeſty, which Cromwell could not help feeling, ſaid "it was very true;" and thenceforth he refuſed to ſit upon criminal cauſes. He ſerved in the parliament of 1654 as one of the knights of the ſhire for Glouceſter, and daily attended to obſtruct ſome of the projects then ſet on foot by the enthuſiaſts. After the death of Oliver, he refuſed to take a commiſſion from his ſon Richard. When the courts of law were re-ſettled, he was in 1660 made chief baron of the Exchequer, and was knighted. He held that ſtation eleven years, with the univerſal character of one of the ableſt and moſt upright judges that ever adorned the Engliſh Bench. He would never converſe upon a cauſe that was likely to come before him in his judicial character. He refuſed to hear the ſtatement of a caſe, from a nobleman intereſted in the deciſion, which ſo offended the peer, that he forthwith went to the king to complain of the affront, as he called it, but the monarch, who underſtood the honourable motives of the judge, bid the nobleman to be contented, for he verily believed that ſir Matthew Hale would uſe him no better if he went to ſolicit him in a cauſe. Though judge Hale was a ſtrict member of the church of England, he was favourable to the rights of conſcience, and friendly to nonconformiſts. The moſt blameable part of his conduct was his condemnation of ſome ſuppoſed witches at Bury St. Edmonds in 1664. He was of great ſervice to the city of London at the period of their tremendous fire, by ſitting at Clifford's Inn, to aſſiſt in compromiſing differences between tenant and landlord. He was raiſed to the poſt of lord chief juſtice of the court of King's Bench in the year 1671, where his high reputation drew after him moſt of the buſineſs of the other courts. He died in February 1676, in the ſixty-ſeventh year of his age, and his remains were interred in the church-yard of Alderſley. He was author of many works on various ſubjects; but thoſe which are beſt known, are his "Contemplations Moral and Divine," three vols: "The Hiſtory of the Pleas of the Crown:" "The original Inſtitution, Power, and Juriſdiction of Parliaments." Burnet's Life of Hale. Biog. Brit.

Hale, in *Geography*, a river of England, in Cornwall, which runs into the ſea near St. Ives.—Alſo, a town of the duchy of Holſtein; ſix miles E. of Krempe.—Alſo, a river of Holſtein, which runs into the Eider; 10 miles S.W. of Renſburg.

Hale, in *Sea Language*, ſignifies *pull*: hence, to *hale* a ſhip, denotes to pull her on ſhore.

HALEBLI, in *Geography*, a town of Aſiatic Turkey, in Natolia; 24 miles S.W. of Eregri.

HALECULA, in *Ichthyology*, a name given by ſome authors to the anchovy. The word is a diminutive of halec, a name for the herring. See Encrasicholus.

HALELÆUM, formed of ἅλς, *ſalt*, and ἔλαιον, *oil*, a medicine compoſed of oil and ſalt, and recommended by the ancients for external uſe in caſes of tumours of the joints.

HALENESS, in *Geography*, a cape on the E. coaſt of Shetland. N. lat. 60° 2'. W. long. 1° 20'.

HALE's Key, a ſmall iſland in the gulf of Mexico, near the coaſt of Eaſt Florida. N. lat. 28° 4'. W. long. 82° 5'.

Hales, John, in *Biography*, uſually diſtinguiſhed by the appellation of "The ever memorable," was born at the city of Bath, in 1584, where he was educated in the elements of learning, and at thirteen years of age he was qualified for the univerſity, and was entered a ſcholar of Corpus Chriſti college. Here he diſtinguiſhed himſelf among his contemporaries for his ſuperior talents, and for his accurate knowledge of the Greek language. He was elected fellow of Merton college in 1605, and aſſiſted ſir Henry Savile in preparing his fine edition of the works of St. Chryſoſtom for the preſs. In 1612 he was appointed Greek lecturer in his college, and profeſſor of that language to the univerſity. In the following year he was admitted fellow of Eton college, and ſhortly after he accompanied Dudley Carleton, ambaſſador to the Hague, in the capacity of his chaplain. In this capacity he had the conſtant opportunity of attending the meetings at the ſynod of Dort, and became, on conviction, a convert from Calviniſm to Arminianiſm. In 1638 archbiſhop Laud appointed him to be his chaplain, and procured for him the canonry of Windſor. This was the more ſurpriſing, as he had on a former occaſion offended the prelate by his treatiſe on ſchiſm, which was handed to him in MS. This circumſtance occaſioned Mr. Hales to write to the archbiſhop that remarkable vindication of himſelf which was firſt printed by way of appendix to the 7th edition of biſhop

Hare's "Difficulties and Diſcouragements, which attend the Study of the Scriptures in the way of private Judgment," in which he declared, that the purſuit of truth had been his only care ever ſince he underſtood the meaning of the word. "For this," ſaid he, "I have forſaken all hopes, all friends, all deſires, which bias me, and hinder me from driving at what I aimed; for this, I have ſpent my money, my means, my youth, my age, and all that I have; that I might remove from myſelf that cenſure of Tertullian, "ſuo vitio quis quid ignorat:" if, with all this coſt and pains, my purchaſe is but error, I may ſafely ſay, to err hath coſt me more, than it has many to find the truth. And truth itſelf ſhall give me this teſtimony at laſt, that if I have miſſed her, it is not my fault, but my misfortune." He ſuffered ſevere hardſhips in the great rebellion, and was frequently reduced to the want even of the neceſſaries of life. He died in May 1656, when he had completed the ſeventy-ſecond year of his age. About three years after his death, there came out a collection of his works in quarto, entitled "Golden Remains of the ever memorable John Hales of Eton College." This collection conſiſts of ſermons, miſcellanies, and letters written on particular occaſions. In 1677 another collection of his works was publiſhed under the title of "Several Tracts by the ever memorable Mr. John Hales." The firſt uniform edition of his works was printed at Glaſgow in three volumes 12mo. The character given of this excellent man by biſhop Pearſon is as follows: "As a Chriſtian none was ever better acquainted with the nature of the goſpel, becauſe none more ſtudious of the knowledge of it, or more curious in the ſearch:—as he was liberal and candid himſelf, ſo he deteſted an impoſing, cenſorious, and intolerant ſpirit in others, and would often ſay, that he would renounce the religion of the church of England to-morrow, if it obliged him to believe that any other Chriſtians would be damned, who did not wiſh him to be ſo." Biog. Brit.

Hales, Alexander, who flouriſhed in the thirteenth century, was a native of Glouceſterſhire, who derived his name from a monaſtery in that county, in which he received the early part of his education. He was ſent to Paris to complete his ſtudies. Here he took his degree, commenced profeſſor of the ſciences of canon law and theology, and drew together a large crowd of pupils, among whom was the celebrated Dun Scotus, and John Fidanza, afterwards known to the world by the name of cardinal Bonaventure. So high was his reputation, and ſo profound was his knowledge, that he obtained the title of the "Irrefragable Doctor." In 1222 he embraced the monaſtic ſtate at Paris, where he ſpent the remainder of his days. He died in 1245, leaving behind him ſeveral publications, but of thoſe that remain no one can with certainty be pronounced as his, except the "Summa univerſæ Theologiæ," or Commentaries on the four Books of Sentences, which he undertook by order of pope Innocent IV. It has gone through many editions, and has been printed at different cities on the continent. Some of his manuſcripts are ſuppoſed to exiſt in the libraries at Milan, Oxford, and Lambeth. Gen. Biog.

Hales, Stephen, a pious and exemplary divine, and eminent natural philoſopher, particularly diſtinguiſhed by his experiments on the phyſiology of plants, was the ſixth ſon of Thomas Hales, eſq. of Beakeborn, or Beckeſbourn, Kent, where he was born in 1677. He was educated in Bene't college, Cambridge, of which he became a fellow in 1702. He afterwards took his degree of M. A. and entered into holy orders. The degree of doctor of divinity was conferred on him by the univerſity of Oxford in 1733. Botany and anatomy formed his ſtudies of relaxation while at Cambridge, his companion in which was the celebrated antiquary Dr. Stukeley. He was advanced ſucceſſively to the perpetual curacy of Teddington, Middleſex, and to the livings of Portlock, Somerſetſhire, and Farringdon, Hampſhire. He married the daughter of a clergyman, who died at the end of two years, leaving no iſſue, nor did he ever marry again. He reſided to the end of his life at Teddington, where he was viſited by perſons of rank and taſte, amongſt others by Frederick late prince of Wales, after whoſe death Dr. Hales was made clerk of the cloſet to the princeſs dowager, who always entertained a high reſpect for him, and after his deceaſe erected a handſome monument to his memory in Weſtminſter-abbey, near that of Handel. On this is his buſt in a large medallion, ſupported by a female figure repreſenting Botany, accompanied by Religion. The epitaph is in Latin. He refuſed a canonry of Windſor, that he might continue to devote himſelf to his parochial duties, and his favourite ſcientific purſuits, and as piety, truth, and virtue were the principles of his character, he lived in univerſal eſteem to the age of 84, dying at Teddington, January 4, 1761, where he was buried, under the church tower, which he had rebuilt at his own expence.

Dr. Hales, having been elected a fellow of the Royal Society in 1717, communicated to that learned body his firſt eſſay in Vegetable Phyſiology, containing an account of ſome experiments concerning the effect of the ſun's heat in raiſing the ſap. In 1727 appeared the firſt edition of his Vegetable Staticks, in 8vo. illuſtrated by plates, of which a ſecond edition was publiſhed in 1731, followed afterwards by ſeveral others. This work was tranſlated into French by Buffon in 1735, and into Italian by a Neapolitan lady named Ardinghelli, in 1756. There are alſo German and Dutch editions. The original book was, in fact, the firſt volume of a work, entitled Statical Eſſays, of which the ſecond, relating to the circulation of the blood in animals, was called Hemaſtaticks, and came out in 1733. In this the ſubject of the urinary calculus alſo is treated chemically and medically. With a laudable view of preventing, as well as curing, the ſufferings and crimes of his fellow-creatures, this good man publiſhed anonymouſly "a friendly admonition to the drinkers of gin, brandy, and other ſpirituous liquors," which has often been reprinted and diſtributed gratis, by thoſe who conſider the temporal and eternal intereſts of their fellow ſubjects, rather than the increaſe of a frequently miſuſed revenue. His invention of a ventilator for mines, priſons, hoſpitals, and the holds of ſhips, laid before the Royal Society in 1741, and applied alſo to the ventilation and conſequent preſervation of corn in granaries, has proved one of the moſt extenſively uſeful contrivances for the preſervation of health and human life. His philoſophy was not a barren accumulation for the ignorant to wonder at, or for its profeſſor to repoſe on in ſottiſh ſelf-ſufficiency and uſeleſneſs: but an inexhauſtible bank, on which his piety and his benevolence were continually drawing. Such philoſophy and ſuch learning alone entitle their poſſeſſors to authority or reſpect, and ſuch are the beſt fruits of religion. In this inſtance at leaſt they were duly honoured, both at home and abroad. The fame of Hales was widely diffuſed throughout the learned world, of which he received a moſt diſtinguiſhed teſtimony, in being elected one of the eight foreign members of the French *Academie des Sciences*, in 1753, in the place of ſir Hans Sloane, who died that ſame year. In 1732 he had been appointed, by the Britiſh government, a truſtee for ſettling a colony in Georgia. He was well acquainted with Mr. Ellis, and other naturaliſts of his day, with whoſe views and purſuits of all kinds he ardently concurred (ſee Ellis); but it does not appear that his foreign correſpondence was extenſive. His name does not occur among

among the correſpondents of Haller, who nevertheleſs held him in the higheſt eſtimation, as a philoſopher and a man.

As a vegetable phyſiologiſt, Dr. Hales is entitled to the higheſt honour. His experiments and remarks led the way to thoſe of Du Hamel, Bonnet, and all that have followed. His accuracy of obſervation, and fidelity of relation, have never been impeached, and his ideas in phyſics, in many inſtances, went before the knowledge of his day, and anticipated future diſcoveries, ſuch are his obſervations relative to airs, and to vegetable ſecretions. One of his more able ſucceſſors in the ſtudy of vegetable phyſiology, has doubted the accuracy of one of his plates only, tab. 11, in which three trees, having been united by engrafting their branches, the intermediate one, by the earth being removed from its roots, is left hanging in the air. An experiment of the late Dr. Hope's at Edinburgh upon three willows, of which the writer of this article has been an eye-witneſs, and which was conducted with ſucceſs in imitation of this of Hales, puts his account beyond all doubt whatever. Aikin's Gen. Biogr. Haller, Bibl. Bot. Hales's works. S.

HALESIA, in *Botany*, ſo named by Ellis, in honour of that illuſtrious vegetable phyſiologiſt the Rev. Dr. Stephen Hales; ſee the preceding article.—Linn. Gen. 237. Schreb. 319. Willd. Sp. Pl. v. 2. 849. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 125. Juſſ. 156. Lamarck. Illuſtr. t. 404. Gærtn. t. 32.—Claſs and order, *Dodecandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Guaiacanæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, minute, of one leaf, with four teeth, permanent. *Cor.* of one petal, bell-ſhaped, inflated, deciduous, rather irregular; its limb in four, unequal, obtuſe, ſhallow, inflexed, or ſlightly ſpreading, lobes. *Stam.* Filaments 12, rarely 16, awl-ſhaped, equal, erect, rather ſhorter than the corolla, inſerted into its tube, and connected together at their baſe; anthers oblong, obtuſe, erect. *Piſt.* Germen inferior, oblong, angular; ſtyle thread-ſhaped, longer than the corolla; ſtigma ſimple. *Peric.* Drupa dry, obovate-oblong, with four ſides and four wings, ſometimes unequal. Nut ſolitary, obovate, pointed at each end, of four marginal cells. *Seeds* ſolitary from the bottom of each cell, oblong, ſlightly curved.

Eſſ. Ch. Calyx with four teeth, ſuperior. Corolla bell-ſhaped, four-cleft. Drupa dry, with four angles. Nut of four cells. Seeds ſolitary.

Obſ. It appears by the various deſcriptions that ſome of the ſeeds are frequently abortive. In our gardens the whole fruit is often altogether ſo.

1. H. *tetraptera*. Linn. Sp. Pl. 636. Cavan. Diſſ. 338. t. 186. Curt. Mag. t. 910. Ellis in Phil. Tranſ. v. 51. 931. t. 22. f. A.—Leaves ovate, pointed. Wings of the fruit equal.—A native of the ſhady margins of rivulets in South Carolina, where Cateſby obſerved it, and figured it in his vol. 1. t. 64. Dr. Garden ſent ſeeds to Mr. Ellis in 1756, when it was firſt raiſed in England, and named by the latter, who publiſhed a plate of it, different from that in the Phil. Tranſ. as remarked by the late Mr. Dryander in his accurate and laborious work, *Bibl. Banks.* v. 3. 282. It forms a moſt elegant ſhrub, known by the name of the Snow-drop tree, being very hardy, and covered in May with innumerable white or reddiſh bell-ſhaped drooping bloſſoms, excellently drawn by Mr. Edwards in Curtis's Magazine. Theſe indeed have no ſcent, but their profuſion and delicacy, as they decorate the naked branches while the leaves are puſhing forth above, render them highly conſpicuous and ornamental. The fineſt plant we know of the *Haleſia* grows in the *Arboretum* at Kew, as big as a wide-ſpreading apple-tree, and truly admirable when in bloom. The *leaves* do not come to their full ſize till the bloſſoms are fallen, and are alternate on downy footſtalks, ovate, pointed, two or three inches long, ſerrated, downy beneath when young, for afterwards they are nearly ſmooth, deciduous. *Fruit*, as well as the *flowers*, pendulous, crowned with the baſe of the ſtyle. It is ſaid the kernels are eatable and very pleaſant to the taſte, but they are very ſmall.

2. H. *diptera*. Linn. Sp. Pl. 636. Cavan. Diſſ. 338. t. 187. Ellis as above, t. 22. f. B.—Leaves ovate, acute. Two oppoſite wings of the fruit very narrow.—Native of the ſame country. We have already, in our biographical article GARDEN, adverted to the confuſion which attends this ſpecies, and indeed the preceding, in the Linnæan herbarium. We profeſs ourſelves entirely ignorant of every thing in this but the fruit, except from the plate in Cavanilles, who ſuſpects it to be a mere variety. The firſt botaniſts in this country were always in doubt concerning *H. diptera*, and the herbarium of Linnæus, when it arrived, was anxiouſly conſulted on this ſubject, but proved to contain nothing certain except the fruit, the leaves paſted by it being full-grown, *Styrax grandifolium*. Notwithſtanding theſe doubts, we find in Mr. Donn's *Hort. Cantab.* the *H. diptera*, ſaid to have been introduced in 1806, and it is to be hoped that ſome light may hereafter be derived from the gardens to diſſipate our uncertainty. We wiſh it may excite the attention of the excellent editor of the Botanical Magazine, as ſuch illuſtrations render that work truly valuable. S.

HALESOWEN, in *Geography*, a market-town and pariſh, ſituated partly in the county of Salop, and partly in that of Worceſter, from which circumſtance it has occaſioned much confuſion and error in general topographical works. The place is not noticed in the population report of 1801, and there being no hiſtory of Shropſhire hitherto publiſhed, its local hiſtory has never been accurately inveſtigated. Gough, in his additions to Camden's Britannia, ſtates, that the pariſh of Haleſowen is "divided into eight townſhips, and five ſubordinate manors." The ſoil is rich and fertile; here are ſome fine woods, and in the manor of Frankley is the ſpring head of the river Stour. Coals have been obtained in the hill townſhip, and in 1745 was dug up "a vaſt foſſil oak." The poſt-way, ſuppoſed to be part of the Icknield-ſtreet, paſſes through part of this pariſh. Oldbury, one of the hamlets, indicates, by its name, its antiquity; and tradition fixes a caſtle and town here. Soon after the Norman conqueſt, the Shropſhire part of this pariſh was given to Roger de Montgomery. In the time of Henry I. it was forfeited to the crown; but king John granted it to Peter de Rutebus, who founded an abbey here. A market and fair were afterwards conferred by Henry III. who alſo inveſted the town with the privileges of a borough, and appointed a high and low bailiff to govern the ſame. Leland ſays, "the tounelet of Haleſowen had a priory of Premonſtratenſians, valued at 280*l.* 13*s.* 2*d.*" This church diſplays ſome parts of ancient architecture, and contains a few monumental memorials. In it were interred John, lord Botetourt, baron of Weoleigh, in the time of Richard II; ſir Hugh Burnell, a great favourite with that monarch; and ſir William Lyttleton, who lived in the time of Henry VII. Some fragments of the abbey ſtill remain. In this pariſh was born Dr. Adam Littleton, author of a Latin dictionary; alſo William Shenſtone, the poet. The latter reſided many years of his life at a villa called the Leaſowes, in the immediate vicinity. This ſmall eſtate he embelliſhed with plantations, and interſperſed theſe with winding-walks, urns, inſcribed tablets, waterfalls, &c. As the poet was admired for the ſimple paſtoral turn of his poems, ſo the place became noted, for its accordance with the maxims there contained. Wheatly, who wrote an intereſting little

volume.

volume on landſcape-gardening, ſpeaking of the Leaſowes, ſays, "It is a perfect picture of Shenſtone's mind—ſimple, elegant, and amiable; and will always ſuggeſt a doubt whether the ſpot inſpired his verſe, or whether, in the ſcenes which he formed, he only realized the paſtoral images which abound in his ſongs." Shenſtone's own lines thus characterize the place:

"——— Calm delight,
Verdant vales, and fountains bright;
Trees that nod on ſloping hills,
Caves that echo tinkling rills."

HALESWORTH, a market-town and pariſh in the hundred of Blything and county of Suffolk, England, is ſeated on the river Blythe, within ten miles of the eaſtern coaſt. The townſhip contains 62 houſes, and 1676 inhabitants, the greater part of whom are employed in manufactures, particularly the ſpinning of worſted. Camden ſays this place was anciently called Hedlsworda, and was an "old town of the Argentons, now Arlingtons, for which Richard Argenton procured the grant of a market from Henry III." The river is rendered navigable to the ſeaport-town of Southwold. In the neighbourhood, ſeveral fields are appropriated to the growth of hemp. In the town is a neat church, alſo a charity-ſchool. Here are a weekly market on Tueſdays, and three annual fairs. The living, with Chedeſton, is a diſcharged rectory.

HALETA, a town of Perſia, in Farſiſtan, on the coaſt of the Perſian gulf; ten miles S.S.E. of Buſheer.

HALEYSBURG, a poſt-town of America, in Luneburg county, Virginia; 235 miles from Waſhington.

HALFAIA, a town of Nubia; ten miles S. of Gerri. N. lat. 15° 45'. E. long. 32° 57'.

HALF-Beams, in *Ship-building*, are to ſupport the deck in large openings, occaſioned by hatch-ways, maſt-rooms, &c. and over the tillar in the gun-room.

Half-blood, in *Law*. See Blood, *whole* and *half*.

Half-bloom. See *Half*-Bloom.

Half-castle *Bay*, in *Geography*, a bay on the S. coaſt of the iſland of St. Chriſtopher; two miles W. of Baſſeterre.

Half-files. See File.

Half-husbandry, in *Agriculture*, a term uſed to ſignify that kind of arable practice, in which two ſorts of crops are grown and cultivated upon the ground at the ſame time; ſuch as oats, potatoes, wheat and potatoes, and ſeveral other ſimilar crops. By the experiments of the late Mr. Cloſe, as detailed in the third volume of the papers of the Bath Society, it was found to be a method which anſwered well in ſome caſes; and it is particularly adviſed as beneficial where the lands are at a conſiderable diſtance from the ſtables, yards, and cow-ſheds, and where the object of carting is of much importance. It muſt, however, in general, be an inconvenient ſort of huſbandry. See Husbandry.

Half-grunie *Iſland*, in *Geography*, one of the ſmaller Shetland iſlands in the North ſea; two miles S. of the iſland of Unſt.

Half-hyde *Bay*, a bay on the W. coaſt of the iſland of Antigua; two miles S. of Reed Point.

Half-mark, *dimidia merca*, in *Law*, is a noble.

Fitzherbert ſays, that in caſe a writ be brought, and the ſeiſin of the demandant, or his anceſtor, alleged; the ſeiſin is not traverſable by the defendant, but he muſt tender the half-mark for the enquiry of the ſeiſin; which is, in plainer terms, that the defendant ſhall not be admitted to deny that the poſſeſſor, or his anceſtor, was ſeiſed of the land in queſtion, and to prove his denial; but that he ſhould be admitted to tender half a mark in money, to have an enquiry made, whether the demandant, &c. were ſeiſed or not.

Half-moon, in *Fortification*. See Demi-lune and Ravelin.

Half-moon, in *Geography*, an extenſive townſhip of America, in Albany county, New York; containing 3851 inhabitants.

Half-moon *Bay*, a bay on the W. coaſt of Jamaica; two miles N. of Orange-bay.—Alſo, a bay on the N. coaſt of St. Chriſtopher; two miles S.E. of Ragged Point.

Half-moon *Fort*, a fort on the iſland of Barbadoes; four miles N. of Speight's Town.

Half-moon *Key*, a ſmall iſland near the S. coaſt of Jamaica; three miles E.N.E. of Portland Point.—Alſo, a ſmall iſland in the bay of Honduras. N. lat. 17° 10'. W. long. 89°.—Alſo, a ſmall iſland in the bay of Honduras, near the E. coaſt of Guanajo. N. lat. 16° 30'. W. long. 86° 20'.

Half-moon *Shoal*, a ſhoal on the Mergui Archipelago, near the E. coaſt of Sullivan's iſland. N. lat. 11° 7'.

Half-note, in *Muſic*, the elementary minor ſecond of the Iſotonic, or equal temperament ſyſtem, the mean ſemitone of Sauveur, is $\frac{1}{12}$th part of the octave, or $1 \div \sqrt[12]{2} = 51.003275\,\Sigma + f + 4\,m$, or $51\,\Sigma + f + 4\frac{1}{2}\,m$; whoſe common logarithm is .9749141.6703, and binary or Euler's log. = .083333 = 4.64980 major commas.

Half-note, or ſemi-tone of the finger-key intervals, are the intervals between the next adjacent notes of a common keyed inſtrument; theſe are not only unequal among themſelves in any propoſed ſyſtem of temperament, but they differ alſo in value or magnitude in every different ſyſtem of tuning. The ſecond term, or f in Mr. Farey's notation, always ſhews to what finger-key a note, forming any interval above C, is to be referred, as obſerved in the article Finger-Keyed *Intervals*; ſee alſo Temperament.

Half-note, *Greater*, of Holden, is the hemitone or ſemitone major, whoſe ratio is $\frac{15}{16} = 57\,\Sigma + f + 5\,m$. See Semitone *Major*.

Half-note, *Leſſer*, of Holden, is the ſemitone minor, $= \frac{24}{25} = 36\,\Sigma + f + 3\,m$.

Half-penny, a copper coin, whoſe value is expreſſed by its name, in reference to the penny.

Half-piece, a meaſure of linen, cambric, or French lawn, (38 Geo. III. c. 76.) = $6\frac{1}{2}$ ells.

Half-ports, in a *Ship*, are portable ſhutters, made of deal, &c. fitted into the ſtops of gun-ports, which have no hanging lids, and though they have a hole cut in them for the gun to go through, yet they keep the water from coming into the ſhip.

Half-seal, is that uſed in chancery, for the ſealing of commiſſions to delegates appointed upon any appeal in eccleſiaſtical or marine cauſes.

Half-tangents, on a ſcale. See Scale and Gunter.

Half-teint, in *Painting*, is, preciſely ſpeaking, the teint which lies exactly mid-way between the extreme light and the extreme dark which any colour is capable of receiving and reflecting. But painters uſe it in a far more general ſenſe, *viz.* as incluſive of almoſt all the intermediate gradations between theſe two points; and therefore regard all objects, in what relates to colour and chiaro-oſcuro, as compoſed of theſe three—light, dark, and middle teint, or half teint.

How much of the viſion of objects is included within the ſphere of half-teint, may be illuſtrated by imagining a ball of ivory placed oppoſite the ſun, and viewed in nearly the ſame direction. In this ſituation a ſmall portion of it will reflect an image of the ſun to the eye of the obſerver, which image, in the language of artiſts, will be termed its high-

light. Towards its lower part a very ſmall portion will be loſt in ſhade. The far greater part of the ball, not reflecting light enough to come under the former of theſe denominations, nor being ſufficiently deprived of it to receive the latter, is recognized under the one we are now diſcuſſing.

When pictures therefore repreſent the ordinary effect of day-light, where the illumination produces breadth of light, as the ſun does, and ſtill more in that kind of light produced by an illumined atmoſphere when the ſun is not clearly ſeen, it is evident that half-teint muſt be the reigning portion of tone and colour in them. Add to this, that as objects recede in the plane of the picture from the ſource of light, they fall into comparative half-teint, their high-lights and ſhadows participating of the hue with which the intervening atmoſphere envelopes them. From both theſe cauſes it may fairly be reckoned that nine-tenths at leaſt, and a greater proportion occaſionally, in ſubjects of this nature, will be half-teint, unleſs artificial ſhadows are introduced.

This being the caſe, too much attention cannot be given to it, as it produces the prevailing tone of colour in the picture. The difficulty lies in giving each colour introduced a gradation participating of the ſame hue, but at the ſame time preſerving the true characters of the original colours in the whole. The reaſon of blending this one hue with all colours is made evident by conſidering the mode of operation adopted by nature, in which all gradations of ſhade are the effect of privation of light, and conſequently of colour which depends upon it, till at laſt every colour is loſt in one dark hue by the total lack of illumination; and that hue is alike with all. It is that hue, therefore, in different degrees, which produces the gradation from extreme light to dark, and which, acting equally on all, produces harmony in the effects by breaking each with a participation of itſelf.

This is the ſimpleſt mode of producing the half-teint, and maintaining it with an harmonious effect throughout the various parts of a picture. It will of courſe allow of intermixtures of reflections, either from parts of the ſame body, as in the folds of draperies, or from different coloured objects acting upon each other; and thus with its ſimplicity, richneſs and variety may be combined. What the hue of the dark ſhade, with which it is produced, may be, depends entirely upon the taſte of the painter and the nature of the illumination. One only regulation can effectively be given. It ought, in its mixture with the light, or local colour, to produce a teint more cool than that, in its hue.

The ſyſtem here propoſed is the beſt for works where minuteneſs of imitation is not required, but rather a greatneſs and ſimplicity of effect. It will not, however, fully reach the richneſs which takes place in nature, particularly in fleſh. There a great degree of colour appears in the half-teints of diverſified hues, of which no ſyſtem will ever produce the exact imitation; and there extreme delicacy and variety are united with ſo much ſubtlety as to be utterly beyond the power of words to convey an idea of. Practice alone and a good eye muſt be the painter's guide in this; and he will find the beſt exemplars of it in the works of Corregio, Rubens, and ſir Joſhua Reynolds. From them he muſt learn to "ſnatch a grace beyond the rules of art."

In pictures of grand, ſublime, or ſerious ſubjects, too large a proportion of half-teint ought not to be introduced. There, large maſſes of ſhade, deep, but clear, are abſolutely requiſite to produce the deſired impreſſion on the mind of the obſerver. Such, for inſtance, is the arrangement in St. Peter Martyr, by Titian; the Deſcent from the Croſs, by Rubens; the Transfiguration, by Raphael, &c.; but in works of a lighter kind, and more agreeable nature, intended to convey the uſual impreſſions produced by common events, it may reign triumphant; particularly where the ſcene is out of doors. The works of Teniers beautifully and ſufficiently illuſtrate this.

HALF-TIMBERS, in *Ship-building*, are the ſhort timbers forward and aft in the cant bodies, which anſwer to the futtocks nearer the lower midſhips.

HALF-TONE, in *Muſic*, or hemitone of the ancients, an interval whoſe ratio is $\frac{2}{2}\frac{4}{5}\frac{3}{6} = 46\,\Sigma + f + 4\,m$, or the LIMMA. See that article.

HALF-TONE, hemitone, or chromatic toniæum of Ariſtoxenus and Holden, half the tone major, $= 2\sqrt{2} \div 3 = 52.003932\,\Sigma + f + 4\,m$, or $52\,\Sigma + f + 4\frac{1}{5}\,m$; whoſe common logarithm is .9744237,3877, and its Euler's log. = .084962, ſuch being its decimal relation to the octave 1. It is = 4.740705 major commas.

HALF-TONE, *Mean*, or half-tone of Dr. Smith (Harmonics, p. 204. ſecond edit.), one-fourth of the major third, $= \sqrt{2} \div \sqrt[4]{5}$, $= 49.251966\,\Sigma + f + 4\,m$, or $49\frac{1}{4}\,\Sigma + f + 4\frac{1}{4}\,m$; whoſe common logarithm is .9757724,9675, and its binary log. or decimal of the octave = .080482, and it contains 4.490705 major commas, or $\frac{1}{4}\,c$ leſs than the laſt. See NOTE and TONE.

HALF-TONGUE, *Medietas linguæ*. See MEDIETAS *linguæ*.

HALF-WORKING, in *Mining*, is a name for the works in a coal-pit, where the face or length-way joints of the coal croſs the level nearly at an angle of 45°, ſuch being otherwiſe called diagonal works, or horn-coal.

HALI, in *Geography*, a town of Arabia, in the province of Hedjas, near the coaſt of the Red ſea, belonging to the ſheriffe of Mecca; 170 miles N.N.W. of Loheia. N. lat. 18° 40′.

HALIAËTOS, in *Ornithology*, the Greek name given by Ariſtotle to the bald buzzard. See FALCO *halietos*.

HALIETUS, a ſpecies of eagle which frequents the ſea, and feeds on fiſhes, called alſo the *aquila marina*, *offifraga*, or oſprey, and the *falco oſſifragus* of Linnæus, which ſee.

HALI-BEIGH, in *Biography*, who flouriſhed about the middle of the 17th century, was a native of Poland, whoſe original name was Albert Bobouſki. At an early age he was taken priſoner by the Tartars, who ſold him to the Turks, by whom he was inſtructed in the religion and ceremonies of the eaſtern prophet. He had a great facility of acquiring languages, and was able to converſe with fluency and accuracy in eighteen tongues. In many of them he was as much at home as the natives themſelves. Hence he became interpreter at the grand Seignor's court. In this ſituation he undertook, at the requeſt of Dr. Smith, chaplain to the Engliſh embaſſy at the Porte, to draw up a treatiſe "concerning the Liturgy of the Turks, their Pilgrimage to Mecca, their Circumciſion, viſiting the Sick, &c." which that gentleman preſented to Dr. Hyde, who publiſhed a Latin verſion of it at Oxford in 1691. Hali tranſlated the Church of England Catechiſm into the Turkiſh language; and afterwards, ſuch were his induſtry and perſeverance, he tranſlated the whole Bible into the ſame tongue, which was ſent in MS. to Leyden, where it ſtill remains in the library belonging to the univerſity. He publiſhed a grammar and dictionary of the Turkiſh language; he furniſhed ſir Paul Rycaut with much valuable information for his work, entitled, "The Preſent State of the Ottoman Empire;" he alſo wrote "A Treatiſe on the Seraglio," in the Italian language, and put into verſe a conſiderable part of the book of Pſalms, to which he added many muſical notes. Moreri. Bayle.

HALIBUT-HEAD, in *Geography*, a lofty mountain, forming

forming the ſouthern extremity of the peninſula of Alaſhka, in the N. Pacific ocean, diſcovered by captain Cook in the year 1778. N. lat. 54° 27′. E. long. 197°.

HALIBUT-*Iſland*, an iſland in the N. Pacific Ocean, about ſeven or eight leagues in circumference; ſix miles from Halibut-head.

HALICACABUM, in *Botany*, from ἁλικος, *maritime*, or *the produce of the ſea-ſhore*, and καλαβη, or καλκαβος, *a red earthen pot*. This name was firſt given to the common winter cherry, *Phyſalis Alkekengi*; nor does the latter part of it, at leaſt, ill apply to the red inflated calyx, which covers that fruit in a ſtate of maturity. But the winter cherry is not a maritime plant; and it is not impoſſible that the firſt part of the word may refer, as Ambroſini ſuſpected, to ἁλς, *ſalt*; in which caſe *halicacabum* will mean a red earthen ſalt-pot, of a particular kind perhaps, with which the inventor of the name, whoever he was, might be converſant, and to which he meant to compare the calyx of the winter cherry. But, like many other names, that of which we are treating has long loſt ſight of its original application and meaning. Fuchſius having called the *Cardioſpermum* of Linnæus, *Halicacabum peregrinum*, becauſe of its inflated calyx, which bears in that reſpect a reſemblance to the above, but has no likeneſs, in colour or ſhape, to any earthen veſſel, this unfortunate name is now retained as the ſpecific appellation of a plant, with which it has no proper connexion, *Cardioſpermum Halicacabum*.

HALICARNASSUS, in *Ancient Geography*, a city of Aſia Minor, formerly the capital of Caria, was ſituated towards the extreme point of the Ceramic gulf, N. of the iſthmus of the peninſula of Cnidus, oppoſite to, and N. of the iſland of Cos. It had a port, excellent fortifications, and great riches. It was particularly diſtinguiſhed by the palace, and various public monuments with which the wealthy Mauſolus, king of Caria, embelliſhed it. Vitruvius has deſcribed the ſuperb edifices which it contained, and which did honour to the munificence of its ſovereign. He cauſed to be conſtructed a commodious port, a temple of Mars, and alſo of Venus and Mercury, and other buildings, which, beſides the magnificent palace in which he reſided, rendered Halicarnaſſus one of the ſtrongeſt and moſt celebrated cities of Aſia. It was particularly famous for the mauſoleum, or tomb, built by Artemiſia, the ſiſter and wife of Mauſolus, who ſucceeded him on the throne. This noble ſtructure, which was reckoned one of the ſeven wonders of the world, was conſtructed by the following artiſts, *viz.* Scopas, Bryaxis, Timotheus, and Leochares. Although the queen died before it was finiſhed, the artiſts, who had undertaken it, perſevered in their labour till they accompliſhed it. This city was alſo celebrated as the birth-place of the hiſtorians Herodotus and Dionyſius, and of the poets Heraclitus and Callimachus. Halicarnaſſus for a long time maintained its liberty and independence. It was firſt ſubjected to Crœſus, king of Lydia; and, among other Greek colonies which were deſpoiled by Cyrus, this city was compelled to ſubmit to the Perſians. Alexander beſieged and took it after a vigorous reſiſtance on the part of the Perſian commanders, Orontobates and Memnon, and a numerous garriſon. Upon the diviſion of the empire it fell to the ſhare of Antigonus, and from him was transferred to the Lagidæ; but it availed itſelf of the opportunity afforded it by the war of Antiochus for recovering its liberty, which was ſecured to it by the Romans in a treaty with Philip. It is now a heap of ruins, and known by the name of "Neſi."

HALICK, a town of Perſia, in the province of Segeſtan; 222 miles S.E. of Zareng.

HALICZ, or HALITSCH, a town of Auſtria, in Poland, a capital of a ſmall country of the ſame name, in the palatinate of Lemburg in Galicia; 58 miles S.E. of Lemburg. N. lat. 49° 5′. E. long. 24° 46′.

HALIEUTICS, HALIEUTICA, ΑΛΕΙΥΤΙΚΑ, formed of ἁλιευς, *fiſherman*, which is derived from ἁλς, *ſea*; books treating of fiſhes, or the art of fiſhing.

We have ſtill extant the *Halieutics* of Oppian.

HALIFAX, in *Geography*, an ancient, populous market town and pariſh, in that diviſion of the Weſt-riding of Yorkſhire called Morley-wapentake, England, is, according to Camden, "a very famous town on the ſlope of a hill, extending from weſt to eaſt. It has not had this name many ages, being before called Horton." By ſome it was alſo called Chapel-in-the-grove. A monkiſh tradition aſcribes the preſent name to an incident that occurred here at a remote period. A prieſt cut off the head of a young woman, and hung it upon a yew tree. This excited the attention of the credulous, and numerous pilgrimages were performed by religious perſons in the vicinity, to this ſpot. The tree was pronounced to be holy, and the place took the new name of Haliz-fæa, or Hali-ſex. In latter times the town acquired particular note from another circumſtance. "The inhabitants within Hardwicke foreſt claimed a right or cuſtom, from time immemorial, that if a felon be taken with goods to the amount of 13½d. ſtolen within their liberty, after being carried before the lord's bailiff, and tried by four frithburgers, from four towns within the ſaid precinct, he was, on condemnation, to be executed on the next market day, after having been ſet in the ſtocks firſt; and after his execution a coroner was to take the verdict of a jury, and ſometimes of thoſe who condemned him. He was to be taken either *handabend*, *i. e.* in the act of ſtealing, or *backberond*, having the goods about him, or confeſſioned." [Gough in addition to Camden.] The mode of execution was ſingular and expeditious. The criminal was placed on a ſcaffold or ſtage, with his head reſting on a block between two vertical poles with grooves: through theſe a heavy axe deſcended and inſtantly ſevered the head from the body. This inſtrument was ſimilar to the noted French guillotine. At Halifax 49 perſons were beheaded between the years 1541 and 1651. The inſtrument or proceſs of execution was denominated "Halifax-gibbet-law." (See a full account of this ancient cuſtom, &c. in Bentley's "Halifax, and its gibbet-law placed in a true light." 12mo. 1761.—Alſo, Wright's "Antiquities of Halifax." 12mo. 1738. and Watſon's "Hiſtory, &c. of Halifax," 4to. 1775."

Halifax was noticed as a mart of manufacture and trade in the reign of Henry VI.: and from its favourable ſituation with reſpect to ſtreams for mills, and contiguity to towns for the diſpoſal of its manufactured goods, it has progreſſively increaſed in houſes and population. The woollen trade may be conſidered its ſtaple article; but various fancy-works are made here. Shalloons and figured ſtuffs are manufactured to a conſiderable extent. The weavers of the ſurrounding villages and hamlets uſually bring their goods undreſſed to the market. The principal articles made here are ſhalloons, plain and figured laſtings, plain and diced ruſſets or florentines, ſerge, ſerge imperial, mooreens, tammies, plain calimancoes, &c. The principal foreign trade of this place was formerly tranſacted through the medium of London merchants, but latterly the manufacturers have exported their own goods from the port of Hull. In the year 1758 there were 34 fulling mills within this pariſh; beſides others for corn. For the convenience of the manufacturers, a large edifice called the Cloth-hall, has been erected here. The building occupies a ſpace of 10,000 ſquare yards, and is divided into 315 rooms or apartments, which are appropriated to the lodgement of goods.

The

The progreſſive advance of this town will develope its proſperity. Camden ſays, that about 1443 it contained but 13 houſes. In 1763 and 1764, according to the vicar's Eaſter-books, in the pariſh were 8244 families. According to the population report of 1801 the town contained 1913 houſes, and 8886 inhabitants, of whom 1840 were deſcribed as being employed in trade and manufactures. The pariſh of Halifax is ſaid to extend from S.E. to N.W. nearly 20 miles in length by about ſeven miles in width, from E. to W. It conſiſts of 26 townſhips or hamlets. Camden ſays it is "famous for the largeneſs of the pariſh, having 11 chapels, (of which two are parochial ones,) and about 12,00 ſouls." The chief buildings of the town are ſeated in a deep valley, and the ſtreets are moſtly very narrow. Here is a weekly market, held by preſcription. The town was repreſented in parliament in the years 1656 and 1658. The church is a large ancient edifice, and contains ſome monuments of eminent perſons. On the north ſide is a chapel or chantry, built by Dr. William Rokely, vicar of this place, and archbiſhop of Dublin in 1511, whoſe body was interred at his cathedral, and heart in the chapel founded by him here. In the town is an alms-houſe, founded in 1641, by Nathaniel Waterhouſe, for 12 old people. The ſame perſon alſo founded a blue-coat hoſpital for 20 children. Halifax gave the title of viſcount 10th Charles II., and of marquis, 1684, to George Saville. Several eminent characters have been born here, among whom may be named the following; John de Sacro Boſco, an eminent mathematician; Dr. Henry Briggs, geometrical profeſſor of Greſham college; Dr. Robert Farrar, biſhop of St. David's, who was burnt in 1555; Dr. David Hartley; Dr. Lake, biſhop of Chicheſter; Sir John Saville, baron of the exchequer, 1598; and Dr. Tillotſon, archbiſhop of Canterbury.

Halifax, a county of Nova Scotia, ſituated in the eaſtern part of the province, and containing, beſides the capital of the ſame name, the townſhips of Londonderry, Truro, Onſlow, Colcheſter, Lawrence, Southampton, Canſo, and Tinmouth. It has numerous bays and rivers; and of the latter the principal are Shabbenacadie, the Petit-codiac, Memramcook, &c.—Alſo, the capital of the above-mentioned county, and of the province of Nova Scotia, ſettled by a colony of Britiſh ſubjects in the year 1749, and ſituated on the bay of Chebucto, which is commodious and ſpacious, of eaſy entrance, and capable of accommodating in perfect ſafety 1000 of the largeſt ſhips. The town ſtands on the weſt ſide of the harbour, on the declivity of a hill, the ſummit of which is 236 feet above the level of the ſea. It is laid out in oblong ſquares, and the ſtreets are parallel, and at right angles. The town, including the ſuburbs, is about two miles in length, and the average breadth is about a quarter of a mile. It is intrenched with forts of timber, and is ſaid to contain 15 or 16,000 inhabitants. On the northern extremity of the town is the king's naval yard, well built and amply ſupplied with ſtores. The harbour is acceſſible at all ſeaſons of the year, and on account of its entrance, ſituation, proximity to the bay of Fundi, and communication by land or water with other parts of the province, and New Brunſwick, it is convenient for fiſhing veſſels, which are protected by a ſmall ſquadron of ſhips of war, which are ſtationed here. It is the reſidence of a governor and other officers. It has an eaſy communication with Pictou, 68 miles to the N.E. on the gulf of St. Lawrence, by a good cart road, finiſhed in 1792. N. lat. 44° 42'. W. long. 63° 26'.—Alſo, a townſhip in Plymouth county, Maſſachuſetts, 35 miles S.E. of Boſton, incorporated in 1734, and containing 612 inhabitants.—Alſo, a townſhip of Windham county, in the ſtate of Vermont, 23 miles E. by S. of Bennington, containing 1600 inhabitants.—Alſo, one of the middle diſtricts of N. Carolina, bounded N. by Virginia, E. by Edenton diſtrict, W. by Hillſborough, and S. by Newbern. This diſtrict is divided into ſeven counties, *viz.* Northampton, Halifax, Martin, Edgcomb, Warren, Franklin, and Naſh, which contain 69,136 inhabitants, including 31,445 ſlaves. The county of the ſame name is bounded N. by Northampton, S. by Edgcomb, E. by Bertie, and W. by Warren, and contains 13,563 inhabitants, of whom 7020 are ſlaves. The chief town, called alſo Halifax, is a poſt town, pleaſantly ſituated on the weſtern bank of the Roanoke, is regularly laid out, and contains, beſides dwelling houſes, a court houſe and goal, 383 miles S.W. by S. of Philadelphia. N. lat. 36° 14'. W. long. 77° 40'.—Alſo, a county of Virginia, bordering on the ſtate of N. Carolina, about 42 miles long and 39 broad, and containing 11,466 free inhabitants and 7911 ſlaves.

Halifax *Bay*, a bay on the N.E. coaſt of New Holland. S. lat. 18° 49'.—Alſo, a bay on the E. coaſt of the iſland of Dominica. N. lat. 15° 40'. W. long. 61° 20'.—Alſo, a bay on the S. coaſt of the iſland of St. John, in the gulf of St. Lawrence. N. lat. 46° 20'. W. long. 63° 30'.

HALIFGOON, a town of Nubia; 25 miles E. of Gerri. N. lat. 15° 35'. E. long. 32° 57'.

HALIGAW, a town of Samogitia; 45 miles N.W. of Miedniki.

HALIGEMOTE. See Halymote.

HALIKARKARA, a town of Turkiſh Armenia, in the government of Erzerum; 20 miles S.S.W. of Cars.

HALIKO, in *Geography*, a town of Sweden, in the government of Abo; 24 miles E. of Abo.

HALILA, a town of Sweden, in Eaſt Bothnia; 40 miles S.E. of Waſa.

HALIMUS, in *Botany*, ἁλιμος, *belonging to the ſea*, the name of a plant in Dioſcorides, whoſe deſcription anſwers well to one or more ſpecies of *Atriplex*. See Atriplex *Halimus*, which is, moſt probably, the very plant originally intended, though Matthiolus has figured the ſecond ſpecies, *A. portulacoides*, as being perhaps the only one to which he had acceſs in Italy; but Cluſius in his *Hiſtoria Plantarum*, v. 1. 53, has given a good repreſentation of the genuine *A. halimus*.

HALING, in *Geography*, a ſmall iſland in the Engliſh channel, ſeparated from the coaſt of Hampſhire, by a narrow channel, in its form triangular, about 3½ miles long, from N. to S., and about two broad, containing three villages, and ſeveral creeks on the E. coaſt. N. lat. 50° 48'. W. long. 0° 57'.

HALIOTIS, in *Conchology*, a genus of univalves, the ſhell of which is dilated, ear-ſhaped, and furniſhed on one ſide with a longitudinal row of orifices; ſpire lateral and nearly concealed.

The animal of the haliotides (or *ſea-ears*) according to Linnæus, is of the limax kind; the head is large, truncated at the extremity, furniſhed with a mouth and two horns of unequal ſize, the one large, conic, and longer than the head, the other ſmall, thick, and priſm-form, and bearing an eye at the tip; the legs are extremely large, elliptic, and the edges appear fringed when the animal is in motion. The ſea-ears have the ſame habits as the limpets, living on the rocks within reach of the regular overflow of the tide at high water. Like the limpet, the animal is defenceleſs beneath, but ſtrongly protected above, by means of its ſhelly covering, and when it moves it is in a ſlow progreſs, the limbs being cautiouſly protruded as occaſion requires, and inſtantly withdrawn on the leaſt diſturbance beneath the ſhell. When quieſcent, it adheres ſo firmly to the rocks, that it cannot be removed without force ſufficient to deſtroy

it, unleſs when off its guard, and then it may be ſtruck off the rock by one dextrous blow. The fleſh is not in much eſteem, though ſometimes eaten, being very hard and tough.

Helbins divides the haliotides into two diſtinct genera, namely, haliotis and ſtomatia, the firſt comprifing thoſe which accord with the Linnæan character, in having the longitudinal row of pores on one ſide of the ſhell, the other, ſuch as are deſtitute of this very eſſential diſtinction. This diviſion of the genus, which cannot but be approved, is followed by Lamarck, and moſt other naturaliſts.

* Genus HALIOTIS. Shell dilated, ear-ſhaped, with very low ſpire, and a row of perforations in a line on one ſide; aperture ample, and longer than broad.

Species.

TUBERCULATA. Shell ſub-ovate, the outſide tranſverſely grooved, rugged and tuberculated. Linn. Fn. Suec. *Auris marina*, Rondel. *Patella major ſ. fera*, Geſn. *Ormier*, Adanſ. *Common ſea-ear*, Donov. Br. Shells.

An inhabitant of the European, Atlantic, and Indian ſeas; the length from four to five inches; the external aſpect rugged, more or leſs tuberculated; tranſverſely wrinkled, and greyiſh, varied with ferruginous; colour within pearly, gloſſed with green; the perforations or orifices between twenty and thirty in number, from four to ſeven of which are pervious.

This ſpecies, the only one of its genus found in the European ſeas, is moſt abundant on the ſhores of Southern Europe, diſappearing gradually towards the north. On the French coaſts the ear-ſhell is very common, as it is alſo in the iſles of Jerſey and Guernſey, from whence it becomes more ſparingly diffuſed, and is even rarely ſeen on the Britiſh ſhores moſt contiguous to thoſe iſles; it is not ſuppoſed to inhabit any of the Britiſh ſeas more to the northward, nor is it met with, we believe, in any higher northern latitudes than thoſe of Denmark and Sweden. There are many varieties of this ſpecies, the principal difference of which conſiſts in the ſize and colours with which the ſhells are variegated.

STRIATA. Shell ovate, ferruginous, tranſverſely wrinkled, and longitudinally ſtriated. Linn.

Inhabits Aſia and Barbary, and reſembles the former, but is ſmaller, with the wrinkles more regular, and not tuberculated; colour ferruginous red, or green ſpotted with white, or red and green varied. The orifices about thirty-eight, of which four or five are pervious.

GIGANTEA. Shell oval, rugged, varied with white and red ſpotted; within margaritaceous; ſpire depreſſed, Chemn.

Native of New Holland; the ſhell from four to ſix inches long, and three inches and a half in breadth; inner lip with a deep margin; the open orifices from three to ſeven.

IRIS. Shell ventricoſe; fine brown, with tranſverſe wrinkles, and longitudinal tuberous plaits; within irideſcent. Favanne, &c.

Inhabits New Zealand; the length four inches and a half; breadth three inches; orifices ſix.

MIDAE. Shell roundiſh, with both ſides poliſhed. Liſter, &c.

A large ſpecies, being ſix or eight inches in length, found in the Indian and African oceans. The ſhell is thick, the outſide longitudinally wrinkled, of a dirty greeniſh colour, and the ſurface uſually incruſted with various marine ſubſtances; the orifices about ten in number.

VARIA. Shell ovate, with longitudinal ſtriæ, the larger ones tuberculated. Linn.

The ſhell of this kind is white, or yellowiſh brown, clouded with dirty green; the ſtriæ elevated, curved parallel, and becoming larger towards the ſpire; orifices twenty or thirty, about five of which are open; the margin unequal. Inhabits India.

MARMORATA. Shell oval, with longitudinal ſtriæ, obſoletely croſſed by others in a tranſverſe direction. Linn.

Varied with brown and white, or brown white and green, or brown, white, green, and red; orifices about thirty, four or five of which are open.

Native of Africa and India. Length from two to four inches.

ASINUM. Shell ſmoothiſh, oblong, with a ſomewhat falcated margin, and elevated nerves on the outſide. Linn.

About three inches long; ſhell marked on the outſide with fine longitudinal ſtriæ, the colour white, green, and brown; the inſide green and pearly; the orifices elevated, about thirty, ſix or ſeven of which are open; all the ſtriæ are granulated near the ſpire, and often dotted with red. The ſpecies inhabits India.

PARVA. Shell ovate, red, with an elevated angle on the ventricoſe part. Linn.

Native of the African and Indian ſeas; the ſhell ſometimes yellowiſh, with decuſſated ſtriæ, and a few tranſverſe plaits; orifices about thirty, about four or five of which are open.

BISTREATA. Shell ovate, greeniſh, ſpotted with brown; tranſverſe ſtriæ elevated and double. Linn.

Shell with a pale purple ſpot under the ſpire, branching into arched rays of the ſame down the back, the right margin acute and ſinuous; within ſilvery; ſix of the orifices open. Native of the African ſeas.

AUSTRALIS. Shell varied with grey, blueiſh, and red, ovate, convex, and cancellated; ſpire prominent, and inflated.

Length three inches and a quarter, breadth an inch leſs; the inſide of the ſhell red and yellow, with a margaritaceous hue; orifices approximate, from ſeven to nine of which are pervious. Inhabits New Zealand.

GUINEENSIS. Shell ovate, ſub-convex, and ſolid, with decuſſated ſtriæ. Schroet.

Native of Guinea, the ſize about two inches and a half long, and two broad; colour dull green, ſpotted with white, and cheſnut towards the ſpire, ſometimes varied with green, red, and white; the inſide margaritaceous, tinged red and greeniſh; margin acute and ſtraight; orifices flattened, and ſix of them open.

GLABRA. Shell ovate, ſmoothiſh, ſolid, varied with white and green; ſpire placed low. Chemn.

Length two inches and a half; breadth an inch and three quarters; inner lip very broad; orifices ſix, open. Native place unknown.

PULCHERIMA. Shell roundiſh, varied with roſy and white; ſtriæ granulated, the ſpire exſerted. Chemn.

A ſmall ſpecies, found in the South ſeas, the length of which is about half an inch; colour within ſilvery, the inner margin very broad, outer lip crenated; orifices thirty, ſix of which are pervious.

VIRGINEA. Shell ovate, with decuſſate undulated ſtriæ; colour dull green, with whitiſh ſpots and bands; within irideſcent. Chemn.

Native of New Zealand; ſhell an inch broad, and an inch and a half in length, with about ſix open orifices.

OVINA. Shell ſomewhat orbicular, depreſſed, wrinkled, varied with white, cheſnut, and yellowiſh, with pervious orifices in the middle, the ſpire open. Chemn.

Country

Country unknown. Shell ſurrounded with a triple elevated circle, and covered with tubercles behind the wrinkles; inner lip broad.

* Genus STOMATIA. Shell dilated, ear-ſhaped, with raiſed ſpire, and without perforations; opening ſimple, entire, and longer than broad.

PHYMOTIS. Ovate, with prickly ribs. Helbins, &c. *Haliotis imperforata*, Gmel.

A rare ſpecies, about an inch in length, found in the Indian ſeas; the ſhell is cinereous, the middle ſpines on the ribs ſtronger, and the margin rather thin and acute.

Another ſpecies of the ſtomatia genus occurs in a foſſil ſtate, and is deſcribed by Gmelin under the name of *Haliotis perverſa*: this, with the recent kind before mentioned, are the only ſpecies of the genus at preſent known.

HALITUS IGNEI. See VAPOUR.

HALKI, in *Geography*, one of the KARTAN *Iſlands*, which ſee.

HALKSHEAD, a cape on the E. coaſt of the duchy of Sleſwick, in the Little Belt; 10 miles E.S.E. of Haderſleben. N. lat. 55° 12'. E. long. 9° 42'.

HALL, a word anciently uſed for a manſion-houſe, or habitation.

HALL, *ſalle*, in *Architecture*, is a large room at the entrance of a fine houſe, palace, or the like.

Vitruvius mentions three ſorts of halls: the *tetraſtyle*, which has four columns ſupporting the plafond, or cieling; the *Corinthian*, which has columns all round, let into the wall, and is vaulted over; and the *Egyptian*, which had a periſtyle of inſulated Corinthian columns, bearing a ſecond order with a cieling: theſe are called *oeci*. The hall is properly the firſt and fineſt partition, or member of an apartment; and in houſes of miniſters of ſtate, public magiſtrates, &c. is that wherein they diſpatch buſineſs, and give audience.

In very magnificent buildings, where the hall is larger and loftier than ordinary, and placed in the middle of the houſe, it is called a *ſaloon*.

The length of a hall ſhould be at leaſt twice and a quarter its breadth, and in great buildings three times its breadth. As to the height of halls, it may be two-thirds of the breadth; and if made with an arched cieling, it will be rendered much handſomer, and leſs ſubject to fire. In this caſe its height is found by dividing its breadth into ſix parts, five of which will be the height from the floor to the under ſide of the key of the arch.

A royal apartment is ſaid to conſiſt of a hall, or chamber of guards, *aula prætoriana*; an ante-chamber, *procamera*; a chamber, *camera*; a cabinet, *conclave*; and a gallery, *porticus*.

HALL is alſo a public building erected for the adminiſtration of the policy and juſtice of a city or corporation.

In this ſenſe we ſay, the *town-hall*, a *company's hall*, &c.

A ſtately building in the city of London, and the great court of judicature for that city, is called *Guild-hall*.

HALL is alſo particularly uſed for a court of juſtice; or an edifice wherein there is one, or more, tribunals.

In Weſtminſter-hall are held the great courts of this kingdom, *viz.* the King's Bench, Chancery, Common-Pleas, and Exchequer.

In adjoining apartments is likewiſe held the high court of parliament. Weſtminſter-hall was the royal palace, or place of reſidence of our ancient kings; who ordinarily held their parliaments, and courts of judicature, in their dwelling-houſes, (as is ſtill done by the king of Spain,) and frequently ſat in perſon in the courts of judicature, as they ſtill do in parliament.

A great part of this palace was burnt under Henry VIII. what remains is ſtill reſerved for the ſaid judicatories.

The great hall, wherein the court of King's Bench, &c. are kept, is ſaid to have been built by William Rufus; others ſay, by Richard I. or II. It is reckoned ſuperior, in point of dimenſions, to any hall in Europe; being 300 feet long, and 100 broad.

HALL, JOSEPH, in *Biography*, a learned Engliſh prelate, was born in 1574 at Aſhby-de-la-Zouch, in Leiceſterſhire, where he received the elementary parts of his education, and from whence he was ſent to Emanuel college, Cambridge, of which he was choſen ſcholar. In due time he took the degrees, received orders, and obtained the rectory of Halſted in Suffolk. In 1597 he publiſhed a collection of ſatires in verſe, entitled "Virgidemiarum," which was the firſt thing by which he was brought into public notice. In 1605 he went with ſir Edmund Bacon to the Spa, in which journey he took a cloſe view of the Romiſh religion, and held a conference with a Jeſuit, at Bruſſels. Upon his return he was nominated one of the prince Henry's chaplains, obtained the donative of Waltham Abbey, in Eſſex, whither he removed, and about the ſame time took the degree of D.D. He next attended upon the viſcount Doncaſter, in his embaſſy to France, and while he was on that miſſion his ſovereign preſented him to the deanery of Worceſter, and when James viſited Scotland in the following year Dr. Hall waited upon him as his chaplain. He was in 1618 appointed to be one of the divines to attend the ſynod of Dort. His want of health obliged him to return in a ſhort time, but before he took leave he preached a Latin diſcourſe before the ſynod, the members of which were ſo highly pleaſed with the compoſition, that they teſtified their reſpect for him by the preſent of a valuable gold medal. Dr. Hall wiſhed, if poſſible, to ſteer the middle courſe in the diſputes between the Arminians and Gomariſts, for he thought that thoſe who agreed in the main point, of ſeparation from the church of Rome, ought not haſtily to differ among one another on points of comparatively trifling importance. He accepted the biſhopric of Exeter in 1627, and was a great favourer of thoſe miniſters, whoſe piety and diligence in the diſcharge of their duties made them ſubject to the charge of Puritaniſm. On this account he was frequently accuſed of hereſy himſelf, and endured much vexation, through the violence of archbiſhop Laud. Nevertheleſs, in the civil wars, when epiſcopacy was brought into danger, he ſtood forth manfully the vindicator of its rights, and principles from the preſs. In 1641 he was tranſlated to the ſee of Norwich, and at the cloſe of the ſame year he was ſufficiently obnoxious to the ruling powers to be noticed and impriſoned in the Tower. His confinement did not laſt long; he was liberated in 1642, when he withdrew to his dioceſe, where he lived in retirement, and highly reſpected by all thoſe who had an opportunity of being acquainted with him. At length he was deprived of his property, but no power, however tyrannical, could take from him the deſire and the will to do good. Out of a mere pittance he contrived to diſtribute a weekly charity to ſeveral poor widows. He died in his eighty-ſecond year, leaving behind him a truly meritorious character. He ranks high among the Engliſh poets of that age, being the firſt who gave a ſpecimen of regular ſatires in our language. The ſatires are ſaid to have more wit than poetry in their compoſition, nevertheleſs Pope ſpoke well of them and admitted their merit. They have been ſeveral times reprinted. On account of his moral writings, he has ſometimes obtained

the title of the Engliſh Seneca. The collection of his works amounts to five volumes, of which three were printed before his death. A ſmall tract, "De Modo ambulandi cum Deo," was printed at Oxford in 1762. Biog. Brit.

HALL, or *Halle*, in *Geography*, a town of the county of Tyrol, on the the river Inn, with conſiderable ſalt-works. The ſalt is dug in large blocks out of a mountain, and after having been cleanſed of its impurities in ſalt-pits, is conveyed in a fluid ſtate, by wooden canals to Innſpruck, where it is boiled to a due conſiſtence in iron pans. It is ſaid to produce a nett profit of 200,000 crowns yearly; 6 miles N.E. of Innſpruck. N. lat. 47° 16'. E. long. 11° 35'.—Alſo, a town of Wurtemberg, late imperial, ſituated on the river Kocher, and ſurrounded with mountains, which abound with ſalt-ſprings; aſſigned to Wurtemberg in 1801; 30 miles N.E. of Stuttgart. N. lat. 49° 7'. E. long 9° 50'. —Alſo, a town of Sweden, in the province of Upland; 20 miles N.E. of Stockholm.

HALL's *Key*, a ſmall iſland in the bay of Honduras N. lat. 16° 10'. W. long. 89° 10'.

HALLAGE, a fee due for cloth brought for ſale to Blackwell-hall in London.

The word is alſo uſed for a toll paid to the lord of a fair, or market, for commodities ſold in the common hall of the place.

HALLAM, in *Geography*, a townſhip of America, in York county, Pennſylvania, containing 1000 inhabitants.

HALLAMAS, in our *Old Writers*, the day of *All-Hallows* or *All-Saints*, *viz.* Nov. 1. It is one of the croſs-quarters of the year, which was computed, in ancient writings, from Hallamas to Candlemas.

HALLAND, in *Geography*, a province of Sweden, bounded N. by Weſt Gothland, E. by Smaland, S. by Skone, and W. by the North ſea. It is generally mountainous, and clothed with oak and birch trees. The corn produced is inſufficient for the inhabitants; but the rivers abound with fiſh, particularly ſalmon. The chief article of trade is cattle; and the employment of the people is grazing and fiſhing. The principal towns are Laholm, Halmſtadt, Falkenburg, and Wardberg.

HALLAREN, a lake of Sweden, in Weſtmanland; 25 miles N. of Upſal.

HALLATON, or HALLOUGHTON, a ſmall market town and pariſh in the hundred of Gartree and county of Leiceſter, England, conſiſts of 149 houſes and 548 inhabitants. Mr. Nichols, in his elaborate hiſtory of Leiceſterſhire, ſays, this place "has been fancifully called a Half-town, or Holy-town." Leland denominates it "a pretty townlet." By an act of parliament, paſſed in 1770, for dividing and incloſing the common fields of Hallaton, they are eſtimated to conſiſt of 3000 acres. A market, which had been long diſcontinued, was revived here in 1767. Here are alſo two annual fairs. Hallaton is diſtinguiſhed by a ſingular and ridiculous ancient annual cuſtom. A piece of land was bequeathed to the uſe and advantage of the rector; who, by the ſame bequeſt, was to provide "two hare-pies, a quantity of ale, and two dozen of penny loaves, to be ſcrambled for on Eaſter Monday, annually." This cuſtom is ſtill continued, but inſtead of hare-pies, the clergyman provides two, made with veal and bacon. About one mile weſt of the town is an encampment called Hallaton-caſtle-hill, which conſiſts of a circular intrenchment, with a lofty conical mount, or keep. Other embankments are connected with, and in the vicinity of this. The church at Hallaton is a large handſome edifice, with a tower and ſpire. Nichols's Hiſtory of Leiceſterſhire, vol. xi. folio, 1798.

HALLE, a town of France, in the department of the Dyle, and chief place of a canton, in the diſtrict of Bruſſels, ſituated on the river Senne; 8 miles S.S.W. of Bruſſels. The place contains 3746, and the canton 12,974 inhabitants, on a territory of 102½ kiliometres, in 15 communes.—Alſo, a town of the duchy of Magdeburg, ſituated on the Saale, and divided into four quarters. This town contains three Lutheran churches, beſides places of worſhip for Calviniſts and Roman Catholics, and a ſynagogue for the Jews. The univerſity, formed out of a military academy, and conſecrated in the year 1694, deſerves particular mention. The number of ſtudents in 1802 was 634, and it has had the honour of educating many of the nobility and even princes. The number of houſes that pay taxes has been eſtimated at 1100, and that of the inhabitants, without including the ſtudents and garriſon, at 13 or 14 thouſand. The magiſtrates enjoy many privileges and conſiderable poſſeſſions. The manufactures of the place are gloves, worſted and ſilk ſtockings, cloth, flannel, fuſtian, linen, tobacco-pipes, china, Hungary water, ſtarch, ribbands, red and yellow Turkey leather, &c. But it has been principally indebted for its origin and celebrity to its ſalt-ſprings. Of theſe there are four, richly productive, in the lower part of the town, called the vale of Halle, and lying on the Saale. This quarter contains from 90 to 100 houſes, where the water from the Saale is boiled for the manufacture of ſalt. It is boiled with pit-coal. The perſons for whoſe profit it is boiled are called "Pfanners," and it is required that they ſhould be freemen of Halle.

The boiling is performed by Hallers, who are deſcendants of the Wends, a people who anciently inhabited the country, and ſtill retain their dreſs, language, and cuſtoms. Halle is an ancient place; mention having been made of it ſo early as the beginning of the ninth century, and it appears that in the year 965 or 966 it was given by the emperor Otho I. to the church of Magdeburg; and by Otho II. it was enlarged and endowed with a charter. It is diſtant 56 miles S. from Magdeburg. N. lat. 51° 31'. E. long. 12 8'.

HALLEEPUTTAH, a town of Bengal; 50 miles N.N.W. of Midnapour.

HALLEGANDHE, a town of Hindooſtan, in the country of Nuſſerpour, on the left bank of the Indus; 25 miles N.N.E. of Nuſſerpour.

HALLEIN, a town of the archbiſhopric of Salzburg, on the Salza, famous for the ſalt ſprings which riſe in the mountain of Durnberg, near the town; from which are annually made 750,000 quintals; 8 miles S.E. of Salzburg.

HALLELUJAH, a term of rejoicing, ſometime ſung, or rehearſed, at the end of verſes on ſuch occaſions.

The word is Hebrew, or rather, it is compoſed of two Hebrew words joined together: one of them הללו, *hallelu*, and the other יה, *jah*; an abridgment of the name of God, יהוה, *Jehovah*. The firſt ſignifies *laudate*, *praiſe ye*; and the other *Dominum*, *the Lord*.

St. Jerom firſt introduced the word hallelujah into the church ſervice: for a conſiderable time it was only uſed once a year in the Latin church, *viz.* at Eaſter; but in the Greek church it was much more frequent. St. Jerom mentions its being ſung at the interments of the dead, which ſtill continues to be in that church, as alſo on ſome occaſions, in the time of Lent.

In the time of Gregory the Great, it was appointed to be ſung all the year round, in the Latin church, which raiſed ſome complaints againſt that pope; as giving too much into the Greek way, and introducing the ceremonies of the church of Conſtantinople into that of Rome. But he excuſed himſelf,

ſelf, by alleging, that this had been the ancient uſe of Rome; and that it had been brought from Conſtantinople at the time when the word hallelujah was firſt introduced under pope Damaſus.

Hallelujah has been ſet to muſic by all the great maſters of eccleſiaſtical harmony; but by none with that ſpirit and divine energy of Handel, in many of his anthems and oratorios: and ſtill with greater ſublimity in the Meſſiah.

HALLENBERG, in *Geography*, a town of Weſtphalia; 30 miles W. S. W. of Caſſel. N. lat. 51° 7'. E. long. 8° 43'.

HALLENCOURT, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Abbeville; 9 miles S. of it. The place contains 1253, and the canton 9580 inhabitants, on a territory of 137½ kiliometres, in 18 communes.

HALLER, Albert, in *Biography*, one of the moſt illuſtrious characters of his age in literature and ſcience, was born at Berne, in Switzerland, on the 18th of October, 1709, where his father was an advocate. The accounts of his diſplay of talents, in his very infancy, are as extraordinary as any upon record. Before five years of age, he was accuſtomed to write down all the new words which he had heard during the day. He afterwards formed, for his own uſe, rules in grammar, arithmetic, and other ſciences; and when nine years old, he had compoſed, for the ſame purpoſe, a Greek and Hebrew lexicon, and a Chaldaic grammar, and had likewiſe compiled an hiſtorical dictionary, containing more than two thouſand lives, extracted from Bayle and Moreri. At the age of ten, he wrote a ſatire in Latin verſe againſt his tutor, a pedant of great harſhneſs and ſeverity. When thirteen he loſt his father, who intended him for the church; and while he thus acquired the liberty of chooſing his ſtudies, he learned alſo the neceſſity of depending entirely upon himſelf. He was ſent for a ſhort time to a public ſchool, where he paſſed his claſſical examinations, before the age preſcribed, and tranſlated into Greek the theme which was required of him only in Latin. In 1723, he ſpent ſome time at Bienne with a phyſician, for the ſtudy of philoſophy, where he was taught the ſyſtem of Deſcartes. Here the ſurrounding beauties of nature awakened in him a poetic enthuſiaſm; and he produced ſeveral compoſitions in German verſe, the preludes of his more mature poems. At this place he commenced the practice, which he continued through life, undiverted by the viciſſitudes of fortune, and which was the foundation of his immenſe literary collections, that of always reading with the pen in his hand, making extracts of every thing memorable in his author, and adding his own judgment of the work. He now decided upon the medical profeſſion, which would enable him to gratify his deſire of inveſtigating the phenomena of nature without reſerve. Towards the end of the ſame year, he went to Tubingen, where he diſſected and ſtudied under Duvernoi and Camerarius with great ardour, and obtained a taſte for a better philoſophy than that of Deſcartes. Here, likewiſe, though but in his ſixteenth year, he renounced wine for ever, and adopted great ſtrictneſs of manners, as a guard againſt future ſeduction, in conſequence of having once been induced to join a party of fellow ſtudents in a debauch. Attracted by the reputation of Boerhaave, he went to Leyden in May 1725; and he has expreſſed, in the moſt affectionate terms, the pleaſure which he derived from the clearneſs, candour, and unaffected eloquence of that admirable preceptor. He alſo diſſected with Albinus, and paid frequent viſits to Ruyſch. On his return to Tubingen he maintained a theſis for his degree, "De Ductu Salivali Coſchwiziano;" a ſubject which he farther purſued at Leyden, in 1727. In this year he viſited England, where he was much noticed by ſir Hans Sloane, Douglas, Cheſelden, and others; and thence went to Paris, and diſſected under Le Dran; but he was ſoon obliged to leave that capital, in conſequence of an information of his having bodies to diſſect in his own apartment being laid againſt him. He proceeded to Baſle, where he went a conſiderable length into the ſtudy of mathematics, under John Bernouilli; and alſo imbibed a deſire to ſtudy botany, to which he had hitherto conceived an averſion: his ardour was excited, he ſays, by the genius of the place, where the Bauhins had reſided, and Stahalin lived; and, what evinces the enthuſiaſm of his mind, as ſoon as he had begun to collect plants, he projected the plan of his great work on the botany of Switzerland, (which was not completed till many years afterwards,) at a time when, he declares, he ſcarcely knew the moſt common plants. Between the years 1728 and 1736 he made ſeveral botanical excurſions, traverſing the Alps of the Valais, Savoy, and Berne. But he did not ſurvey theſe ſcenes with the eye of a naturaliſt only; they awakened all his poetical enthuſiaſm; and his "Poem on the Alps," compoſed in his twenty-firſt year, which was followed by various ethic epiſtles, and other pieces, placed his name high among the votaries of the German muſe. Indeed, he is conſidered as the firſt who gave ſublimity, richneſs, and harmony to the poetical language of Germany; and twenty-two ſucceſſive editions of his poems in the original, with the tranſlations into other languages, ſufficiently atteſt the general applauſe with which they were received.

Having ſettled in his native city about 1730, he employed himſelf in giving public lectures on anatomy: but his ſucceſs among his countrymen was very limited; and his ſatirical poems, although now deſtroyed, were not forgotten, he perceived, by his rivals and enemies; and theſe, together with ſome irritability of temper, did not tend to acquire him friends. In 1731 he married a young lady of good family, who entered readily into his taſte and purſuits, and conſtituted the great happineſs of his life: ſhe brought him three children. The publication of ſome detached pieces in anatomy and botany had gained him conſiderable reputation abroad; and in 1736, he received an invitation from the king of Great Britain, George II., to undertake the profeſſorſhip of anatomy, ſurgery, and botany in the univerſity which he had recently founded at Göttingen. With great reluctance at abandoning his native country, and eſpecially in ſeparating his wife from her connections, he deemed it prudent to accept this advantageous offer. But his arrival at Göttingen was rendered melancholy by the death of his beloved wife, from the conſequence of ſome injury which ſhe had received by the overturning of the carriage on the road. With a view to relieve his grief, he commenced at once the duties of his office, and entered with great ardour into the purſuits of his pupils; the moſt induſtrious of whom he encouraged to take ſome ſingle object of the animal economy for their inveſtigation, and to devote themſelves to experimental inquiries reſpecting it, in which he gave his aſſiſtance. At the ſame time he was indefatigable, during the ſeventeen years which he ſpent at Göttingen, in the proſecution of ſimilar reſearches; having conſtantly in view that great reform in phyſiology, which his writings ultimately effected. For he knew, that by multiplied obſervation and experiment alone could that maſs of metaphyſical and chemical jargon be expunged from the doctrines of the animal economy, and phyſiology be rendered as certain as the other phyſical ſciences. During theſe labours in the cauſe of ſcience, he obtained the friendſhip and patronage

of

of baron de Munchauſen, prime miniſter in the electorate of Hanover, who even anticipated his wiſhes, in promoting the welfare of the univerſity of Göttingen. Through this miniſter's influence with the king, Haller obtained for the univerſity the eſtabliſhment of a botanic garden, an anatomical theatre, a ſchool for ſurgery, and for midwifery, with a hoſpital for lying-in-women, a ſchool for deſign, with a view to the accurate delineation of the objects of natural hiſtory; and he alſo formed the plan of an academy of ſciences, of which he was appointed perpetual preſident. He received many honourable teſtimonies of his fame during his reſidence at Göttingen; being elected into the Royal Society of Stockholm in 1748, and into that of London in 1749; and having the titles of phyſician to George II. and of king's counſellor, conferred upon him by that monarch, at whoſe requeſt he was alſo raiſed to the rank of nobility, by the emperor Francis, in 1749, with the title of baron Von Haller. This title, however, he always declined; for although it might have been advantageous to his family at Göttingen, it would be deſpiſed as a badge of vanity and an odious diſtinction in Switzerland.

We may be excuſed from enumerating here the titles of all the diſſertations, on particular topics of anatomy and phyſiology, which Haller publiſhed during his reſidence at Göttingen; many of theſe were collected, reviſed, and reprinted in 1751, under the title of "Opuſcula Anatomica, de reſpiratione, de monſtris, aliaque minora, quæ recenſuit, emendavit, auxit. Addidit alia inedita, et novas icones," Gottingæ, 8vo. The principal publications within the period juſt mentioned were, 1. His great work on the botany of Switzerland, the firſt edition of which appeared in 1742, under the title of "Enumeratio methodica Stirpium Helvetiæ indigenarum, &c." folio; which, after undergoing conſiderable corrections and augmentations, was given under its perfect form, entitled "Hiſtoria Stirpium Helvetiæ indigenarum," in 1768, in three vols. folio, with many plates. This admirable work, which was the moſt copious then publiſhed, was remarkably accurate in ſpecific diſtinctions, and very full upon the economical and medicinal uſes of the plants. The arrangement was peculiar to himſelf, and he ſhewed an unwillingneſs to adopt the improvements of Linnæus.—2. "Commentarii ad Hermanni Boerhaave Prælectiones Academicas, &c." which appeared in ſeven ſucceſſive volumes, 8vo., between the years 1739 and 1744. Immediately after the death of his venerable preceptor, Boerhaave, in 1738, Haller undertook to publiſh his "Prelections," from a MS. copy of his own, collated with others.—3. In 1743, he began to publiſh faſciculi of anatomical plates in folio, particularly relative to the blood-veſſels *in ſitu*, which are among the moſt valuable of theſe helps to the ſtudy of the human frame. They were entitled "Icones Anatomicarum, quibus præcipuæ partes corporis humani delineatæ continentur, Faſcic." The plates amount to thirty-ſix in number.—4 The firſt edition of his excellent little work, "Primæ Lineæ Phyſiologiæ in uſum Prælectionum Academicarum," was publiſhed in 1747, 8vo. It paſſed through many ſubſequent editions, and ſeveral tranſlations, and is an outline of the ſyſtem afterwards developed in his larger work.—5. In 1751 he publiſhed at Amſterdam another work of great labour and research, viz. an edition of Boerhaave's "Methodus Studii Medici," with ſo many additions, that by much the greater part was his own; it may be conſidered as a prelude to his later "Bibliothecæ."—6. He delivered two academical diſcourſes in 1752, in which he propoſed his peculiar opinions reſpecting the properties of ſenſibility and irritability in living bodies; they were written in French, (of which language he had a perfect command,) under the title of "Diſſertation ſur les Parties ſenſibles et irritables des Animaux," 12mo. Lauſanne. Beſides theſe works, he printed a catalogue of plants, growing in the botanic garden, and in the diſtrict of Göttingen;—obſervations made in a journey to the Hercynian foreſt in 1738, and an "Iter Helveticum, anni 1739;" and likewiſe a number of botanical papers, which were collected in his "Opuſcula Botanica," 1749, 8vo., or contained in the memoirs of the Göttingen academy, and other periodical works.

After a reſidence of about ſeventeen years at Göttingen, Haller reſolved upon reviſiting his native country; and in 1753 he returned to Berne, where he eſtabliſhed himſelf, and was received by his countrymen with much gratulation. He had been elected a member of the ſovereign council in 1745, and now became one of the magiſtrates by lot, and entered with ardour into the duties of a citizen. In 1757 he was deputed to effect a reform in the academy of Lauſanne; and in the year following was appointed director of the ſalt-works for ſix years, during which he reſided at La Roche. In this ſervice he contributed to the public benefit, by introducing many improvements, which at once diminiſhed the price of ſalt, and amended its quality. On his return from La Roche, he was elected a member of the ſupreme conſiſtory, and of the chamber of appeals for the German part of the canton; he was alſo made perpetual aſſeſſor of the council of health, and was choſen one of the three deputies of the grand council to ſettle the differences with Geneva. He was active in the formation of an hoſpital for orphans, laid the plan of a ſchool for the more opulent citizens, and he prevailed upon the government of Berne to augment the ſalaries of the clergy of the Pays de Vaud, and was intruſted with the diſtribution of them. While occupied in theſe concerns, his pen was alſo employed for the public ſervice, in drawing up a variety of ſtate memoirs, and writing many public letters. His mind had not been long turned to political objects, when he wrote three political romances in German, exhibiting his views of the nature of government, which were at once profound, ingenious, and humane. In the firſt, entitled "Ufong," he gave the picture of a virtuous, but deſpotic monarch: in the ſecond, or "Alfred," he repreſented a limited monarchy, like that of England, in which both the nobles and the people have preſerved their right to a ſhare in the government; and in the third, or "Fabius and Cato," he drew the picture of a well regulated ariſtocracy, the form to which he was moſt partial. To complete the plan, he ſhould have deſcribed a perfect democracy; but this would probably have given offence to the ariſtocratic ſpirit of the inhabitants of Berne. Theſe works were compoſed between the years 1771 and 1774.

Yet, amidſt all the exertions which his duty as a magiſtrate induced him to make, his profeſſional ſtudies were unremitted. In 1755 he publiſhed his "Opuſcula Pathologica, quibus ſectiones cadaverum morboſorum potiſſimum continentur," at Lauſanne, 8vo. In the following year he printed "Deux Mémoires ſur le Mouvement du Sang, et ſur les Effets de la Saignée, &c.;" and a continuation of his inquiries reſpecting irritability and ſenſibility, entitled "Memoires ſur la Nature ſenſible et irritable des Parties du Corps Animal," Lauſanne, 4 vols. 12mo.—He likewiſe ſent to the preſs a collection of theſes, under the title of "Diſputationes Chirurgicæ ſelectæ," ibid. 1755—6, in five vols. 4to. Soon afterwards his great work, "Elementa Phyſiologiæ Corporis Humani," began to make its appearance: the firſt volume, in quarto, having been publiſhed at

Lauſanne

Lauſanne in 1757, and the eighth and laſt in 1766. Such a vaſt collection of well authenticated facts, with ſo much accurate deſcription and truly ſcientific argumentation, ſo well arranged, was never perhaps brought together upon any ſubject; and of this the author's own diſcoveries made a very conſpicuous part. His other anatomical writings are principally compriſed in his "Opera anatomica minora," in three vols. quarto, 1762—68. He had publiſhed in 1758, "Deux Mémoires ſur la Formation du Cœur dans le Poulet, &c." containing the reſult of three years' experiments at Berne, in which he traced, hour after hour, the developement of the parts of the chick *in ovo*, and eſpecially of the heart. There are beſides many ſeparate tracts, which it would be tedious to enumerate.

But before we complete the catalogue of the labours of Haller in favour of medical ſcience, we have to notice a ſeries of volumes, which alone would have entitled him to the praiſe of a life well ſpent in the ſervice of his profeſſion. Theſe were his "Bibliothecæ," containing a chronological liſt of every book, of every age, country, and language, reſpecting ſubjects connected with medicine, which had come to his knowledge; with brief analyſes, and enumerations of novelties and peculiarities of all the principal works. Of theſe he publiſhed "Bibliotheca Botanica," two vols. 4to. 1771;—"Bibliotheca Chirurgica," two vols. 4to. 1774;—"Bibliotheca Anatomica," two vols. 4to. 1774;—"Bibliotheca Medicinæ Practicæ," 4 vols. 4to. 1776—88; of which laſt only two were publiſhed by himſelf, the other two by Drs. Tribolet and Brandis, from his papers, with additions. In examining theſe works, we ſtand aſtoniſhed at the compaſs of his reading, which has embraced not only all the beſt known publications of all countries, but many which are probably unknown by name to moſt ſtudents of the ſame nation. They form indeed a moſt invaluable body of bibliography in their ſeveral claſſes, and are of extenſive utility to the biographer.

He ultimately received every teſtimony of the general eſtimation in which he was held throughout Europe. The king of England requeſted him to accept of the chancellorſhip of the univerſity of Göttingen; the king of Pruſſia offered him that of Halle; and the ſovereign of Ruſſia propoſed to him an eſtabliſhment at Peterſburgh; but theſe he reſpectfully declined. The learned ſocieties of Europe vied with each other in evincing their regard for him, and fourteen of theſe enrolled him among their members. Indeed ſuch was the eſteem in which he was held, wherever the ſciences were cultivated, that all ſtrangers, even the ſovereign princes, who travelled into Switzerland, paid a kind of homage to his reputation and learning, by perſonally viſiting him. The king of Sweden ſent him the order of the Polar Star, accompanied with the warmeſt aſſurances of his eſteem.

From his earlieſt youth, Haller had evinced a high ſenſe of the value of religion to ſociety and to perſonal happineſs, and had made it the object of his moſt ſerious inquiries. He compoſed, in German, "Letters to his Daughter, on the Truth of the Chriſtian Religion," and ſome other tracts; and all his writings are expreſſive of his love of virtue. His religious ſentiments, however, were not entirely capable of tranquillizing the irritability of temper which ever accompanied him. He was impatient under the attacks of painful diſeaſe, and reſorted to violent methods to remove them; this, however, ſeemed to ariſe from the interruptions which they occaſioned in his literary occupations, which were in a manner neceſſary to his exiſtence. His conſtitution, though delicate, was ſtrengthened by temperance; and notwithſtanding his intenſe application to ſtudy, at all hours, his life was prolonged to the ſeventieth year. He had been ſubject to inflammatory diſorders; but in his laſt years he was afflicted with a diſeaſe in the bladder, the exceſſive pain of which was only to be palliated by large and continued doſes of opium, and which finally proved fatal. The laſt ſcene was perfectly tranquil and collected: he marked the gradual decay of his organs, and, with his finger on his wriſt, he ſaid to M. Roſelet, his phyſician, "My friend, I am dying,—the artery no longer beats:" and immediately expired. This took place on the 12th of December, 1777.

Baron Haller was one of the moſt univerſally informed men in Europe. He wrote and ſpoke with equal facility the German, French, and Latin languages, and read all the other tongues of civilized Europe, except the Sclavonic dialects. His acquaintance with books was ſo extenſive, that it would be difficult to point out any of the leaſt note, whether inſtructive or entertaining, which he had not peruſed, and of which the contents did not dwell upon his memory. Beſides the maſs of writings already mentioned, he maintained a very extenſive correſpondence with the learned of different countries. Of letters written to him, ſix volumes in Latin, and three in German have been publiſhed; but his own have only caſually appeared. In his perſon he was tall and well proportioned: his countenance, which had acquired a ſerious caſt, from his ſhort ſight and habitual tenſion of the muſcles, was full of expreſſion. His elocution was free, ſtrong and conciſe. Haller had eleven children, eight of whom he lived to ſee eſtabliſhed. His firſt wife, we have already obſerved, died on their arrival at Göttingen. Two years afterwards, he married a ſecond wife of his own country, who died in child-bed; and he contracted a third marriage, with a German lady, which proved more fortunate, for ſhe was the companion of the remainder of his life. His eldeſt ſon, Gottlieb Emanuel, was a member of the ſovereign council of Berne, and diſtinguiſhed himſelf in the purſuit of ſcience. See Henry's Mem. of Albert de Haller. Gen. Biog. Eloy. Dict. Hiſt.

Haller, Gottlieb Emanuel, ſon of the preceding, was born at Nyon, in the canton of Berne, in the year 1735, and diſtinguiſhed himſelf by an extenſive knowledge in the hiſtory of his native country, and of numiſmatics, which, by the treatiſes that he gave to the public, ſeem to have been the favourite objects of his purſuit. He was author of ſeveral works, of which, the one entitled "Library of the Hiſtory of Switzerland, and of every thing relating to it, ſyſtematically arranged, and in chronological order," is ſaid to be a laſting monument of the author's aſſiduity as well as accuracy, and one that may prove of great uſe to the future hiſtorian. Another valuable work was entitled "Cabinet of Swiſs Coins and Medals." He died at Berne in 1786, in the fifty-firſt year of his age. Gen. Biog.

HALLERIA, in *Botany*, ſo named by Linnæus as a juſt compliment to the ſubſequently famous Haller, at that time his confidential friend, though afterwards eſtranged from him by feelings of rivalſhip, which Linnæus, on their firſt appearance, ingenuouſly and moſt affectionately deprecated, though in vain. See his letter publiſhed by Haller himſelf in *Epiſt. ad Hallerum*, v. 1. 284; in the preceding part of which, moreover, the naming of the *Halleria*, in the *Hortus Cliffortianus*, is announced.—Linn. Gen. 314. Schreb. 411. Willd. Sp. Pl. v. 3. 310. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 349. Juſſ. 118. Lamarck Illuſtr. t. 546.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Scrophulariæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, flattiſh, ſpreading, permanent, divided half way down into three very obtuſe ſegments, the upper one twice the breadth of the others, ſometimes cloven. *Cor.* of one petal, ringent; tube roundiſh at the baſe, inflated and incurved in the upper part; limb oblique, erect, four-cleft, its upper ſegment rather the longeſt, obtuſe, notched, lateral ones ſhorter, broader, and ſharper, loweſt very ſhort, ovate, acute. *Stam.* Filaments four, briſtle-ſhaped, ſtraight, inſerted into the tube, all longer than the corolla, two longer than the reſt; anthers roundiſh, two-lobed. *Piſt.* Germen ſuperior, ovate, pointed; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma ſimple. *Peric.* Berry roundiſh, pointed, of two cells, its baſe encompaſſed with the permanent calyx. *Seeds* ſeveral, ſmall, round, and, according to Fabricius, bordered.

Eſſ. Ch. Calyx three-lobed, ſpreading, permanent. Corolla tubular, curved, inflated, unequally four-cleft. Berry ſuperior, pointed, of two cells. Seeds numerous, bordered.

Obſ. We cannot account for the evident error of Linnæus in deſcribing the germen as inferior. Juſſieu is led by analogy to ſuſpect the fruit to be rather a pulpy capſule, than a true berry, which we can neither verify nor refute, having never ſeen it at all advancing towards maturity in any collection.

1. H. *lucida.* Linn. Sp. Pl. 872. Thunb. Nov. Act. Upſ. v. 6. 39. (Lonicera foliis lucidis acuminatis dentatis, fructu rotundo; Burm. Afric. 244. t. 89. f. 2.)—Leaves ovate, pointed, finely ſerrated. Calyx three-cleft.—Found in woods at the Cape of Good Hope. A ſmooth, upright *ſhrub*, with numerous, oppoſite, elongated, twiggy, ſquariſh *branches*. *Leaves* oppoſite, ſtalked, ovate, pointed, an inch long, thin, ſhining, ſmooth, veiny, finely and ſharply ſerrated, the tips of the ſerratures rather callous. *Stipulas* none. *Flower-ſtalks* axillary, two or three together in the lower parts of the branches, rather longer than the foot-ſtalks, ſimple, drooping, each bearing a pair of ſmall acute *bracteas*. *Flowers* crimſon, ſcarcely an inch long, their *calyx*, according to Thunberg, three-cleft, as we find it, though he, through inadvertence, ſays "three-leaved." This ſhrub is kept in green-houſes rather for the ſake of its name than its beauty, the flowers being ſparingly produced, and not at all ſtriking. Its habit moreover is looſe and ſtraggling. This is the ſpecies figured in Lamarck.

2. H. *elliptica.* Thunb. ibid. (H. lucida β; Linn. Sp. Pl. 872. Lonicera folio acuto ſerrato, flore pendulo, fructu oblongo; Burm. Afric. 243. t. 89. f. 1.)—Leaves elliptical, acute, ſtrongly ſerrated. Calyx four-cleft.—Common, according to Thunberg, in woods at the Cape of Good Hope, eſpecially on the brinks of rivulets below the Table mountain and others, flowering in July. He deſcribes the *leaves* as thicker than the former, tapering at each end, and much more coarſely ſerrated, with rounded ſinuſes betwixt their teeth. *Corolla* leſs curved. We have ſeen no ſpecimen, but the plant may poſſibly be found by chance in ſome garden. Willdenow ſays the calyx of this was four-cleft in every flower that he examined, which is much more probable than Thunberg's account of its being five-cleft, and would naturally ariſe from the broadeſt lobe being cloven, which in the other ſpecies is undivided.—The preciſe length of the ſtamens is perhaps variable in both.

HALLERIA, in *Gardening*, comprehends a plant of the ſhrubby evergreen kind, of which the ſpecies is the African fly honeyſuckle, (H. lucida.)

Method of Culture.—It is capable of being increaſed by means of cuttings, which ſhould be carefully planted in pots filled with light earth, during the ſummer ſeaſon. When the plants are come up they may remain expoſed during the warm ſummer months, plentiful ſupplies of water being given them, but in the winter ſeaſon they ſhould be houſed at the ſame time with myrtles and other ſimilar plants, of the hardy exotic claſs, that demand much free air when the weather is mild and open.

Plants of this kind are alſo capable of being propagated, by ſowing the ſeeds well ripened in pots of light friable mould, plunging them in the hot-bed, by which practice they frequently ſucceed in a perfect manner.

Theſe plants are found to afford ornament and variety in collections of the green-houſe kind. See GREEN-HOUSE *Plants*.

HALLERMUND, in *Geography*, a country of Weſtphalia, incorporated with the principality of Calenberg.

HALLEROW HEAD, a cape on the E. coaſt of the iſland of South Ronaldſha, N. lat. 58° 38'. W. long. 2° 47'.

HALLET, JOSEPH, in *Biography*, was born at Exeter in the year 1692, and was educated under the care of Mr. Pierce, who was co-paſtor with the elder Mr. Hallet, to a congregation of Proteſtant diſſenters in that city. Joſeph was admitted to the exerciſe of the miniſtry in the year 1713, and in 1722 he ſucceeded his father as co-paſtor with Mr. Pierce. Prior to this event he had engaged in the controverſy, then warmly carried on in the weſt of England, concerning the Trinity: he had, in the year 1720, ſtood forth the vindicator of the ſcripture doctrine of the unity of God, in a treatiſe entitled "The Unity of God not inconſiſtent with the Divinity of Chriſt; being Remarks upon Dr. Waterland's Vindication, relating to the Unity of God, and to the Object of Worſhip." The author intended this piece as an introduction, for the unlearned reader, to the true nature of the controverſy indicated in the title; taking himſelf the ſame ſide of the queſtion as that maintained by Dr. Clarke. He publiſhed other pieces on the ſame ſubject, but his reputation is chiefly founded on his work, entitled "A free and impartial ſtudy of the Holy Scriptures recommended, being Notes on ſome peculiar Texts, with Diſcourſes and Obſervations." This work conſiſts of three volumes, but they were publiſhed at different times. They furniſh much intereſting matter, and the diſcourſes and obſervations, beſides diſplaying extenſive learning, an intimate acquaintance with eccleſiaſtical antiquities, and much ingenious reaſoning on important and very uſeful topics, will alſo gratify a reader's curioſity by remarks and diſquiſitions on ſome ſubjects of ſpeculative enquiry. Our author publiſhed many other works which were highly eſteemed by his contemporaries; ſome of theſe were practical, and concerned all Chriſtians, and ſome were on controverſial ſubjects, in which he defended the principles of our holy religion, in oppoſition to the unbelievers of that period. Mr. Hallet died in 1744, when he was about fifty-two years of age. He poſſeſſed a great ſhare of learning, which he applied to the valuable purpoſe of explaining and defending our common Chriſtianity, and his "Notes," &c. were held in high eſtimation by biblical ſtudents of all claſſes, and they introduced him to the acquaintance of many perſons, eminent for learning and knowledge in his time, both at home and abroad. As a miniſter of the goſpel he diſcharged the various duties incumbent upon him, with exemplary diligence and fidelity, and in private life he ſecured the eſteem and regard of all who knew him. Biog. Brit.

HALLEY, EDMUND, was born at Haggerſton, in the vicinity

vicinity of London, in the year 1656. He was educated at St. Paul's ſchool, under the care of the learned Dr. Thomas Gale, where he diſtinguiſhed himſelf for his claſſical attainments, and for the advances which he made in mathematics. In 1673 he was entered a gentleman commoner of Queen's college, Oxford, where he applied himſelf with all the zeal, of which a great mind is capable, to the ſtudies of the place, particularly to mathematics and aſtronomy. Of his ſkill in the latter he exhibited a ſtriking proof, when he was only nineteen years of age, by communicating to the world, his "Direct and Geometrical Method of finding the Aphelia and Excentricity of the Planets." In the month of June, 1675, he made ſome curious obſervations on an eclipſe of the moon, and in the following year he communicated certain diſcoveries reſpecting a ſpot in the ſun, by which the rotation of that body, on its axis, was fully aſcertained. He, about the ſame period, obſerved an occultation of Mars by the moon, which he afterwards applied, with others, in fixing upon the longitude of the Cape of Good Hope. He paid great attention to the motions of Jupiter and Saturn, and by his obſervations was enabled to correct the beſt aſtronomical tables then extant. Having formed the deſign of completing the ſcheme of the heavens, by the addition of the ſtars near the ſouth pole, he went in 1676 to St. Helena, and perfected his catalogue, which at his return he preſented to king Charles II., who gave him a mandamus to the univerſity of Oxford for the degree of M. A. At the ſame time he was elected fellow of the royal ſociety, and in 1679 he went to Dantzic to confer with Hevelius about the diſpute between him and Dr. Hooke, reſpecting the preference of plain or glaſs ſights in aſtronomical inſtruments. He arrived at that city in May, and immediately entered upon ſome obſervations with the Poliſh aſtronomer, which were cloſely continued till the middle of July, when he returned to England. Before he left Dantzic, he gave the ſtrongeſt teſtimonies of his candour, by writing to Hevelius, acknowledging the ſurpriſing accuracy of his obſervations, and voluntarily offering himſelf as a witneſs of the almoſt incredible perfection of his inſtruments, againſt any perſon who ſhould call the matter in queſtion. In 1680 appeared the great comet, which Mr. Halley firſt obſerved in his paſſage from Dover to Calais. He afterwards completed his obſervations upon it at the Royal Obſervatory. From thence he went to Italy with his friend and ſchoolfellow Mr. Nelſon, and in their journey Mr. Halley had a ſight of the comet, as it appeared for the ſecond time, in its return from the ſun. So highly were Mr. Halley's talents appreciated, that Mr. Newton committed to his care, in 1686, the publication of the "Principia," to which the editor prefixed a copy of verſes. He had, previouſly to this, turned his thoughts to the ſubject of Kepler's problem, and, after ſome reflection, he concluded from it, that the centripetal force muſt decreaſe in the inverſe proportion of the ſquares of the diſtances. As, however, he was enabled to give a demonſtration of the fact, he applied firſt to ſir Chriſtopher Wren, and afterwards to Newton, by whom he had all his difficulties ſolved. About this period he publiſhed "The Hiſtory and phyſical Cauſe of the Trade Winds and Monſoons, together with a chart repreſenting their direction, &c." In 1687 he undertook to explain the cauſe of a natural phenomenon, which had till then baffled the reſearches of ſcientific men. It had been obſerved that the Mediterranean never ſwells, although there is no viſible diſcharge of the prodigious quantity of water that runs into it from nine large rivers, beſides ſeveral ſmall ones, and the conſtant ſetting in of the current at the mouth of the ſtrait: this he ſhewed, by a vaſt number of experiments, was occaſioned by evaporation cauſed by the ſun and wind. The circulation he ſuppoſed was carried on by the winds driving theſe vapours to the mountains, where, being collected, they form ſprings, the ſtreams from which uniting become rivulets, and many of theſe meeting together in the valleys become rivers, which at length empty themſelves into the ſea. Hence there is an equilibrium between the expenditure and receipt in the ocean. Mr. Halley's was a moſt active life, his purſuits about this period are mentioned with applauſe and admiration by a French eulogiſt, M. Mairan: after noticing his papers on the "Winds," and on "Gunnery," which had been read before the Royal Society, ſoon after he became the aſſiſtant ſecretary to that learned body, he ſaid, "theſe were followed by queſtions on the nature of light and tranſparent bodies; a determination of the degrees of mortality, in order to adjuſt the valuation of annuities on lives; and many other works, in almoſt all ſciences; aſtronomy, geometry, and algebra; optics and dioptrics; balliſtics, and artillery; ſpeculative and experimental philoſophy; natural hiſtory, antiquities, phyſiology, and criticiſm; being about twenty-five or thirty diſſertations, which he produced during ten years of his reſidence at London, and all abounding with ideas new, ſingular, and uſeful." In the year 1692, Mr. Halley reſigned his office as aſſiſtant ſecretary to the Royal Society, and in 1696, upon the eſtabliſhment of five different mints, for the re-coinage of the ſilver ſpecie, he was conſtituted comptroller of the office of Cheſter. In the year 1701 he publiſhed "A general Chart, ſhewing at one View the Variation of the Compaſs in all thoſe Seas where the Engliſh Navigators were acquainted." This valuable work was the reſult of actual obſervation, for which he traverſed the vaſt ocean: in one of his voyages he ſailed acroſs the two hemiſpheres, till the ice in the cold regions of the ſouth obſtructed his navigation; and on his voyage home touched at St. Helena, the coaſt of Brazil, Barbadoes, Cape Verde, Madeira, the Canaries, and the coaſt of Barbary. This chart laid a ſure foundation for the diſcovery of the law by which the variation changes in all parts of the world. After this he was employed by the king to obſerve the courſe of the tides, with the longitude and latitude of the principal headlands in the Britiſh channel. In 1702, he was ſent by queen Anne to take a ſurvey of the ports in Dalmatia, with a view of forming a ſafe and convenient harbour for ſhipping in the Auſtrian territories on the Adriatic. Being introduced to the emperor, he gave him an account of two harbours on the Iſtrian coaſt, and was preſented by his majeſty with a valuable diamond ring, taken from his own finger, and alſo with a letter, ſtrongly recommending him to queen Anne, written with the emperer's own hand. In 1703 he was appointed Savilian profeſſor of geometry at Oxford, in the room of Dr. Wallis, deceaſed, and on this occaſion he was honoured by the univerſity with the degree of doctor of laws. He now undertook and completed a tranſlation from the Arabic into Latin, of "Apollonius de ſectione Rationis," which had been begun by Dr. Edward Bernard. He next, in conjunction with Dr. Gregory, ſet about preparing for the preſs "Apollonius's Conics;" to this he added the treatiſe of "Serenus on the Section of the Cylinder and Cone." He publiſhed, in 1708, his "Miſcellanea Curioſa," in three volumes 8vo., containing many original pieces of his own. In 1713 he ſucceeded to the office of ſecretary to the Royal Society, and in 1719 he was made aſtronomer-royal by king George I., inſtead of Mr. Flamſtead, who was lately dead. At Greenwich he exerted all his powers in completing the theory of the moon's motion, and in other obſervations on the heavens. For eighteen years he watched the celeſtial bodies with

the cloſeſt attention, ſcarcely miſſing a meridian view of the moon during all that time, when the weather was favourable, and performing the whole buſineſs of the obſervatory without any aſſiſtant. In 1729 he was admitted a foreign member of the Academy of Sciences at Paris. He lived to the very advanced age of eighty-ſix, and died in his chair without a groan. He poſſeſſed all the qualifications neceſſary for the aſtronomer, the naturaliſt, the ſcholar, and the philoſopher: he was candid in his judgment; uniform and blameleſs in his manners; always communicative, and totally diſintereſted. His great qualifications were tempered with a vein of gaiety, which neither his abſtracted ſpeculations, the infirmities of old age, nor the palſy itſelf were able to impair. He was author of ſome other works beſides thoſe already noticed, as "Aſtronomical Tables, with precepts, for computing the Places of the Sun, Moon, Planets, and Comets." "A Synopſis of the Aſtronomy of Comets," annexed to Dr. Gregory's "Elements of Aſtronomy," and a great number of valuable papers in the Philoſophical Tranſactions. Biog. Brit.

HALLIA, in *Botany*, ſo named by Thunberg, apparently in honour of Birger Martin Hall, whoſe Theſis, publiſhed at Upſal, June 25, 1762, was the *Nectaria Florum* of Linnæus, re-printed in Amoen. Acad. v. 6. 263. We find no mention of this gentleman elſewhere. Thunb. Prod. 131. Willd. Sp. Pl. v. 3. 1168.—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, its limb regular, in five deep equal ſegments. *Cor.* papilionaceous. Standard inverſely heart-ſhaped, reflexed. Wings oblong, ſtraight. Keel ſtraight, compreſſed, obtuſe. *Stam.* Filaments diadelphous, ſimple and nine-cleft, inflexed; anthers roundiſh. *Piſt.* Germen ſuperior, compreſſed; ſtyle awl-ſhaped, inflexed like the ſtamens, permanent; ſtigma ſimple. *Peric.* Legume oblong, compreſſed, of two valves and one cell. *Seed* ſolitary, kidney-ſhaped.

Eſſ. Ch. Calyx regular, in five deep ſegments. Legume of two valves and one cell. Seed ſolitary.

Thunberg has founded this genus on two or three Linnæan ſpecies of *Hedyſarum*, which certainly require to be ſeparated from thence, and to which he has added ſome new ones. Willdenow has properly ſubjoined to theſe *H. ſororium* of Linnæus. The whole, therefore, ſtand as follows:

1. H. *alata*. Thunb.—"Leaves oblong, ſmooth. Stipulas decurrent. Stem winged." Native of the Cape of Good Hope.

2. H. *flaccida*. Thunb.—"Leaves lanceolate, pointed, ſmooth. Stalks ſingle-flowered, the length of the leaves." From the ſame country.

3. H. *virgata*. Thunb.—"Leaves lanceolate, pointed, ſmooth. Stalks ſingle-flowered, ſhorter than the leaf."—Gathered alſo at the Cape by Thunberg, whoſe ſpecific definitions are all we know of theſe plants.

4. H. *cordata*. Thunb. (Hedyſarum cordatum; Thunb. Nov. Act. Upſ. v. 6. 41. t. 1. f. 1. Jacq. Hort. Schonbr. v. 3. 25. t. 296. Glycine monophylla; Linn. Mant. 101.)—Leaves heart-ſhaped, elongated, acute. Stalks ſingle-flowered, the length of the leaf. Stipulas lanceolate.—Native of the Cape of Good Hope. *Stems* ſeveral, upright or ſpreading, ſhrubby, branched, ſomewhat zigzag, ſlender, triangular, ſtriated, hairy. *Leaves* alternate, ſtalked, ſimple, an inch or inch and half long, dependent, heart-ſhaped at the baſe, elongated and tapering to a point, with a terminal briſtle, entire, with a ſtrong midrib and numerous fine veins, either ſmooth, or beſprinkled with long ſcattered hairs. *Stipulas* lanceolate, acute, widely ſpreading. *Flower-ſtalks* axillary, ſolitary, ſpreading, ſingle-flowered, about as long as the leaves, having a joint, with two or three minute *bracteas*, near the top. *Flowers* ſmall, pale violet, variegated with purple and blue.

5. H. *Aſarina*. Thunb. (Crotalaria Aſarina; Berg. Cap. 194.)—Leaves heart-ſhaped, rounded, obtuſe, hairy. Stalks ſingle-flowered, the length of the leaf. Stipulas ovate.—Gathered by Bergius at the Cape of Good Hope. The *ſtems* are procumbent, long, ſlender, branched, triangular, ſtriated, hairy. *Leaves* not an inch long, much ſhorter, broader, and rounder than in the laſt, as are alſo the *ſtipulas*. *Flowers* much like the laſt, on capillary, hairy ſtalks. *Petals* elegantly veiny. *Germen* lanceolate, with a long point, very hairy, ſtalked. *Legume* (according to Bergius) ovate, tapering at each end, hairy, of one cell, ſtanding on a ſtalk out of the permanent calyx. The deſcription of the preceding in the *Mantiſſa*, p. 101, is made from this ſpecies, though the other is the marked ſpecimen, and Linnæus in his copy of Bergius, has clearly diſtinguiſhed them by a manuſcript note, ſaying, "my *Glycine monophylla* differs," (from this plant of Bergius) "in having an upright triangular ſtem, and narrower leaves; otherwiſe they are alike."

6. H. *hirta*. Willd. n. 6. (Lens, elatines folio ſingulari, minor, piloſa, floribus luteis; Pluk. Amalth. 131. t. 154. f. 8. Lens maderaſpatana, elatines folio; Petiv. Gazoph. t. 30. f. 11.)—Leaves heart-ſhaped, rounded, nearly ſeſſile, fringed, without ſtipulas. Flower-ſtalks ſcarcely longer than the leaf-ſtalks.—Gathered by Kœnig at Tranquebar. Plukenet had it from Madras. It is ſtrange that Bergius ſhould quote his very diſſimilar figure for the laſt, but Willdenow has rightly diſtinguiſhed them. Linnæus, in his latter days, confounded the preſent with his own *Crotalaria biflora*, and Dahl took it for the very different *Hedyſarum nummulariifolium*. Numerous hairy *ſtems*, a ſpan long, moſtly branched, ſpring from one root, and ſpread flat on the ground, covered with a multitude of crowded alternate *leaves* on ſhort thick ſtalks. Theſe *leaves* are without ſtipulas, between a quarter and half an inch long, heart-ſhaped, obtuſe, a little oblique, glaucous, dotted, fringed with coarſe tawny hairs, but otherwiſe nearly ſmooth. *Flowers* ſolitary, axillary, yellow, on hairy ſtalks, rather exceeding the footſtalks. *Legume* elliptical, rigid, ſomewhat tumid, poliſhed nearly or quite ſmooth, about half as big as the leaves.—Plukenet's t. 86. f. 4. is probably intended for this plant.

7. H. *imbricata*. Thunb. (Hedyſarum imbricatum; Linn. Suppl. 330. Thunb. Nov. Act. Upſ. v. 6. 42. t. 1. f. 2.)—Leaves heart-ſhaped, pointed, ſeſſile, imbricated. Stipulas ovate, acute. Flowers ſeſſile, axillary.—Gathered by Thunberg at the Cape of Good Hope, in graſſy fields beyond Swellendam, along with *H. cordata*, n. 4. The *ſtems* are diffuſe and branched, a foot or more in length, angular, ſtriated, hairy. *Leaves* moſt numerous at the ends of the branches, where they are crowded or imbricated in two ranks. They are ſeſſile, heart-ſhaped, about half an inch broad, and rather longer, acute and tipped with a briſtle, finely reticulated with veins, and fringed. *Stipulas* ſpreading, pale, ovate, acute, ſtriated, fringed. *Flowers* concealed by the leaves, ſolitary, ſeſſile, with a very hairy calyx, purple veiny corolla, and ovate ſmall ſmooth legume.

8. H. *ſororia*. Willd. n. 8. (Hedyſarum ſororium; Linn. Mant. 270. Glycine monophyllos; Burm. Ind. 161. t. 50. f. 2. Lens maderaſpatana, nummulariæ folio maculato; Petiv. Gazoph. t. 33. f. 1.)—Leaves roundiſh, kidney-ſhaped, emarginate, nearly ſmooth. Flowers racemoſe.—Native of the Eaſt Indies. *Stem* herbaceous, long, trailing, triangular, ſtriated,

striated, ſmooth. *Leaves* alternate, diſtant, ſpeckled with brown, about an inch wide, but not ſo long, emarginate at the baſe and ſummit, ſtanding on ſlender ſtalks nearly their own length, which ſometimes bear auricles; the veins are a little hairy at the back. *Stipulas* ſmall, cloſe-preſſed, broad at their baſe, taper-pointed, ribbed, ſmooth. *Flower-ſtalks* axillary, ſolitary, ſlender, hairy, racemoſe, about as long as the leaves, each bearing from four to eight oppoſite ſtalked *flowers*, with a broad concave ribbed deciduous *bractea* to each. The *calyx*, at leaſt when in fruit, ſeems broader, ſhorter, and leſs divided, than the character of this genus requires. *Corolla* ſmall. *Legume* ſemi-elliptical, compreſſed, ſmooth, veiny, the thinner edge wavy.—Linnæus juſtly remarks that the leaves are, ſtrictly ſpeaking, ternate, their ſtalk bearing, near the baſe, "two ſmall oval ſtalked ſtipulas." He ought rather to have called them leaflets, or auricles, for there are real membranous ſtipulas beſides, in their proper place; neither are theſe auricles by any means conſtant. Willdenow's deſcription is compiled from the *Mantiſſa* and *Syſt. Veg.* In the latter, the legume is ſaid to have two joints; a character equally foreign to the generic deſcription, and to truth. But it is curious to obſerve the cauſe of this error in the Linnæan ſpecimen, where two of the legumes are ſo placed as to give this appearance. Hence the value of original ſpecimens; and as we copy nothing without the inſpection of ſuch, except we avow it, we hope our labours may contribute to the aſſiſtance of thoſe who come after us, and to the accuracy of botanical ſcience.

HALLIAPOUR, in *Geography*, a town of Hindooſtan, in Oude; 22 miles S.W. of Fyzabad.

HALLIAR, a circar of Hindooſtan, in Guzerat, on the N. ſide of the gulf of Cutch, about 40 miles long, and 20 broad.

HALLIARDS, or HALYARDS, in a *Ship*, are the ropes or tacks uſually employed to hoiſt or lower any ſail upon its reſpective maſt or ſtay.

HALLIER. See BRAMBLE-*net*.

HALLIER, FRANCIS, in *Biography*, was born at Chartres in the year 1595; and having received a good education, he taught philoſophy at the univerſity of Paris. He afterwards engaged as private tutor to the abbé d'Alincourt, Ferdinand de Neufville, who was afterwards biſhop of Chartres. He accompanied the young man to Rome, where he acquired the eſteem of pope Urban VIII.: from Rome he went firſt to Naples, then to Greece, and afterwards to England. In 1637, he publiſhed a work, which fixed on him a very high reputation at Rome, and in his own country; it was entitled "De ſacris Electionibus et Ordinationibus ex antiquo et novo Eccleſiæ Ritu." For this the French clergy ſettled on him a penſion of eight hundred livres. Cardinal Richlieu was deſirous of engaging M. Hallier as his confeſſor, and cardinal Barberini wiſhed to attach him to his perſon, by the offer of a penſion, but a love of independence induced him to decline their propoſals. In 1656, he paid another viſit to Rome, in order to receive from the hands of pope Alexander VII. the bulls of inveſtiture to the biſhopric of Cavaillon, to which he had been nominated by the king. This new dignity he enjoyed but a ſhort time, having had his faculties impaired by a paralytic ſeizure, to which he fell a ſacrifice in 1659, when he was in the ſixty-fifth year of his age. M. Hallier was author of ſeveral works, beſides the one already mentioned, but as they related chiefly to his controverſies with the Jeſuits, their titles need not be tranſcribed.

HALLIER, in *Rural Economy*, a name provincially applied to a perſon who carts, or lends articles of different kinds for hire.

HALLIFAX, SAMUEL, in *Biography*, was born at Cheſterfield, in Derbyſhire, in the year 1730. After paſſing through the grammar ſchool, he went to Jeſus college, Cambridge, where he purſued his ſtudies with reputation, and took his degrees. He afterwards removed to Trinity hall, where he took his degree of doctor of laws. For many years he held the profeſſorſhip of Arabic at Cambridge, which he reſigned in 1770, upon his being appointed regius-profeſſor of civil law in the univerſity. In the exerciſe of this office he acquired much celebrity by a public courſe of lectures which he delivered, containing a compariſon between the Roman laws and thoſe of England. In 1775, the degree of doctor of divinity was conferred upon him by royal mandate, he was created chaplain to his majeſty, and appointed maſter of the faculties in Doctor's Commons. He now obtained conſiderable church preferment, and in the year 1781 was advanced to the biſhopric of Glouceſter, whence he was tranſlated to the ſee of St. Aſaph in 1787. He died in 1790, in the ſixtieth year of his age. He publiſhed ſome ſingle ſermons: "Three Sermons preached before the Univerſity of Cambridge," on the attempts to aboliſh ſubſcriptions in 1772: and "Twelve Sermons on the Prophecies concerning the Chriſtian Church, and in particular concerning the Church of Papal Rome," which are held in high eſteem: he was author likewiſe of an "Analyſis of Biſhop Butler's Analogy of Religion, natural and revealed." Gen. Biog.

HALLIGS, in *Geology*, are low alluvial iſlands, overflowed by the higheſt of the tides on the coaſt of Denmark, having an artificial raiſed mount in their higheſt parts, on which the houſes of their inhabitants are built; theſe halligs are particularly deſcribed in M. de Luc's "Geological Travels," vol. i. pages 367 and 388.

HALLNAS, in *Geography*, a town of Sweden, in the province of Upland; 45 miles N. of Upſal.

HALLOWELL, a flouriſhing poſt-town of America, in Kennebeck county, and ſtate of Maine, at the head of the tide-waters, on the W. ſide of Kennebeck river. An academy has been eſtabliſhed in this place, and endowed with a conſiderable fund in lands: 195 miles N. by E. of Boſton. *Hallowell Hook* lies on the ſame ſide of the river, three miles below the town. The whole townſhip, interſected nearly in the centre by Kennebeck river, contains 1364 inhabitants.

HALLOWELL *Townſhip*, a townſhip in the county of Prince Edward, Upper Canada, at the ſouthern part of the county, open to lake Ontario.

HALLSIO, a town of Sweden, in the province of Jamtland; 43 miles N. W. of Sundſwall.

HALLSTATT, a town of Auſtria, on the lake Hallſtatter, near which is a ſalt-mine; 25 miles S. of Gemunden.

HALMOE, a ſmall iſland in the Baltic, belonging to Denmark, near the N.E. coaſt of the iſland of Arroe. N. lat. 54 53'. E. long. 10 30'.

HALMOTE, or HALIMOTE, from the Saxon *hrale*, *hall*; and *gemot*, *meeting*; is the ſame with what we now call a *court-baron*; the word implying, a meeting of the tenants of the ſame hall or manor.

"Omnis cauſa terminetur, vel hundredo, vel comitatu, vel halimote, ſecum habentium, vel dominorum curia." LL. Hen. I. cap. 10. Halmote and halimote are often confounded with *folkmote*, though originally they were diſtinct courts. The halmote being properly the lord's court, or a court-baron held in the manor, in which differences between the tenants were determined.

The name is ſtill retained at Luſton, and other places in Herefordſhire.

HALMOTE is ſometimes alſo taken for a convention of citizens in their public hall, more properly called *folk-mote*.

HALMSTADT, in *Geography*, a ſea-port town of Sweden, in Alland, at the mouth of the Niſſa, in which are flouriſhing woollen manufactures, and a rich ſalmon fiſhery; 96 miles W. of Carlſcrona. N. lat. 56° 40'. E. long 12° 37'.

HALMYRAX, a name given by Pliny to the natrum of the ancients, when found in a dry form on the ſurface of the earth.

HALMYRHAGA, in the *Materia Medica of the Ancients*, was a name given by ſome authors to the natrum, when in a purer ſtate. They diſtinguiſhed, according to Pliny, two kinds of this ſalt; one they called by this name halmerhaga, which was the purer; the other, which was fouler, and mixed with earth, they called agrium. The firſt of theſe they had from Media, the other from Thrace.

HALMYRODES, of ἅλμυρος, *ſalt*; from ἅλς, *ſea*; a word uſed by Hippocrates, as the name of a peculiar ſpecies of fever, in which, as Galen explains it, the external parts, when touched, communicate ſuch an itching ſenſation, as is perceived on touching ſalt ſubſtances. The ſame word is ſometimes uſed to expreſs a roughneſs of the ſkin, and is applied to many of the excretions, when ſalt and acrimonious.

HALNA, in *Geography*, a town of Sweden, in Weſt Gothland; 79 miles E.N.E. of Uddevalla.

HALO, or CORONA, a luminous and ſometimes coloured circle appearing occaſionally around the heavenly bodies, but more eſpecially about the ſun and moon. This phenomenon is at times accompanied with others, ſuch as *parhelia*, or mock-ſuns, *paraſelenes*, or mock-moons, *anthelia*, or glories. All theſe appearances are occaſioned by the refraction, reflection, or inflection of light falling upon, or paſſing near the concrete vapour floating in the atmoſphere; but they have not yet received that ſatisfactory explanation which has been given to the rainbow, a phenomenon nearly related to them.

Halos are obſerved in an atmoſphere ſomewhat foggy or miſty, but not in a cloudy nor clear one: a thin hazineſs in the higher regions of the air in ſummer, and in the lower regions in winter, commonly occaſions ſome appearance of the halo, the characters of which are various, according to circumſtances. In ſummer, halos are conſidered by the farmers as portentous of wind or rain.

It is remarkable that the large halos ſurrounding the ſun and moon are commonly of given diameters, namely, about 23° or 24°, or double that magnitude, 47°. Sometimes two concentric halos of theſe dimenſions are ſeen at the ſame time. Philoſophers do not ſeem to have aſcertained the above facts by frequent and careful obſervation; but if they are found to be true, they muſt evidently lead to the theory of thoſe curious appearances. Halos, however, are often much ſmaller, not extending more than one or two degrees from the luminous body. The order of the colours in halos is differently deſcribed by different obſervers; this may be partly from the diverſity of the phenomena, and partly from the indiſtinctneſs of the colours. In thoſe which Newton obſerved in 1692, they were in the following order, reckoning from the inſide; in the innermoſt were blue, white, and red; in the middle were purple, blue, green, yellow, and pale red; in the innermoſt, pale blue and pale red. M. Huygens obſerved red next the ſun, and a pale blue outward. Sometimes they are red on the inſide, and white on the outſide. M. Weidler obſerved one that was yellow on the inſide, and white on the outſide. In France one was obſerved in 1683, the middle of which was white; after which followed a border of red, next to it was blue, then green, and the outermoſt circle was a bright red. In 1728 one was ſeen of a pale red outwardly, then followed yellow, and then green, terminated by white. Mr. Wood of Cambridge deſcribes three very brilliant halos which appeared round the moon, Nov. 30, 1785, the order of the colours beginning from the moon was white, of conſiderable breadth, yellow, orange, red; violet, green, yellowiſh, red; violet, green, yellowiſh, red. The red of a fourth was ſo faint as to be ſcarcely viſible. The radii of theſe rings might be about one, two, and three degrees, but they were not meaſured. The red and violet in each caſe ſeemed contiguous. Dec. 3d, a ſingle halo appeared round the moon; its diameter was about 2½ degrees, and the colours as in the firſt of thoſe mentioned above; the red of a ſecond was juſt ſeen, and its diameter, as far as could be determined by the naked eye, was double the diameter of the firſt. On the 20th Nov. 1802, ſir H. C. Engleſield obſerved the ſun to be accompanied by uncommon halos and parhelia, at Richmond in Surrey. The weather was ſhowery, and the ſky of a turbid appearance, indicating rain; and the ſun, which was 14° high, ſhone with a faint and watery light. The circle, or halo, neareſt the ſun was of about 24° radius; its breadth was about 1°; it was of a pale yellowiſh light, but had no tendency to priſmatic colours. The exterior circle was 48° from the ſun, and about 1½° in breadth, being evidently broader than the inner circles. It was tinged throughout with the priſmatic colours, though only red, green, and blue were diſtinctly viſible. The red was neareſt the ſun; the blue very faint. The brightneſs of the circle was about that of the ſecondary rainbow. There were two parhelia accompanying the inner halo; the one faint, on the left-hand; the other, very bright, over the ſun; its light was more vivid than that of the ſun at the time, and whiter than the reſt of the circle in which it was, with ſomething of the priſmatic tints. It was about 2 broad, but ill defined, eſpecially on the ſide oppoſite to the ſun. From each ſide of the bright light proceeded a bright ray, which had a double curvature very diſtinct, being firſt convex towards the ſun, and then concave. The lower edge of theſe rays was tolerably well defined; the upper edge melted away into the ſky with a ſort of ſtreakineſs. They grew both narrower and fainter towards their termination, and they reached pretty near to the other circle. The whole form of the parhelion and its rays bore a ſtriking reſemblance to the body and extended wings of a long-winged bird, ſuch as an eagle.

Various have been the theories and opinions of optical writers concerning halos. Deſcartes concludes that the phenomena are occaſioned by the refraction of light in the round particles of ice floating in the atmoſphere at the time; the variations in the diameter of the halo, he conceives, are owing to the greater or leſs protuberance of the icy globules; he corroborates this hypotheſis by the obſervation that halos are not ſeen when it rains. Gaſſendi ſuppoſes a halo to be formed in the ſame manner as a rainbow; the rays of light being, in both caſes, twice refracted, and once reflected within each drop of rain, and that the difference between them is wholly owing to their different ſituation, with reſpect to the obſerver. This author does not, however, ſufficiently explain his ideas on this ſubject, nor illuſtrate them by a ſuitable diagram. Dechales alſo endeavours to ſhew that the generation of the halo is ſimilar to that of the rainbow. He ſays, if a ſphere of glaſs, filled with water,

water, be placed in the beams of the ſun, there will not only be two circles of coloured light on the ſide next the ſun, conſtituting the two rainbows, but there will alſo be another on the part oppoſite to the ſun, the rays of which, meeting in a point, afterwards diverge and form a coloured circle, which may be exhibited on paper. The colours will appear, to an eye placed any where, on the ſurface of the cone; he found the angle which the diameter of the cone's baſe ſubtended at the vertex was 46°. The application of this to explain the effect of the ſun's light on ſmall globular particles of fogs is obvious; and he follows it up with ſome pertinent remarks upon the greater dilution of the colours in halos than in rainbows, and ſhews, that in favourable circumſtances, a halo of 46° diameter ſhould always be formed. Theſe obſervations, made prior to the optical diſcoveries of Newton, certainly do great credit to the author's ſagacity. Huygens alſo formed a theory to account for halos and parhelia; he aſſumes the exiſtence of hailſtones, opaque in the centre, and tranſparent in the circumference, by the help of which he explains the formation of halos; he further aſſumes cylindrical particles of ice in the air of a ſimilar conſtitution, by which he explains the parhelia. This theory, though mentioned in favourable terms by Newton, and afterwards by Dr. Smith, does not ſeem to have many advocates at preſent. Marriotte accounts for the formation of ſmall coronas by the tranſmiſſion of light through aqueous vapour, where it ſuffers two refractions without any intermediate reflection. The larger coronas of 45° diameter, he conceives, are effected by means of icy particles of vapour in the ſhape of equiangular priſms floating in the air, and refracting the rays of light into the priſmatic colours. This idea is ſupported by microſcopic obſervations on the hoar froſt, and on the particles of ſnow in which ſuch priſmatic figures are found. He obſerves, that the red rays are within, or neareſt the ſun, as being leaſt refracted, and the blue without. He calculates the angle of refraction to be ſuch as to agree with the phenomenon. This explanation is certainly ingenious, and entitled to conſideration. Newton does not ſeem to have given particular attention to halos; but he ſuppoſes the larger and more regular ones to be formed by two refractions without any reflection, in the manner of Dechales; and the ſmaller ones, he conceives, are formed on the ſame principle as the colours of thin plates. He corroborates this conjecture by an obſervation made in June, 1692. He ſaw, by reflection, in a veſſel of ſtagnant water, three halos, or rings of colours, about the ſun, which have been deſcribed above; the diameter of the ſecond was about 9½°, that of the firſt about 5° or 6°, and that of the third about 12°. He once obſerved coronas around the moon nearly ſimilar to theſe. In the 3d vol. of the Mancheſter Memoirs, Mr. Wood has given a theory of halos: he ſuppoſes, with Dr. Halley, that vapour conſiſts of hollow ſpherules of water, filled with an elaſtic fluid, and that the rays of light, in paſſing through theſe, are refracted and reflected, ſo as to produce halos in a manner ſimilar to that of the production of rainbows in the ordinary ſolid drops of rain. Laſtly, Dr. Young, in his Natural Philoſophy, 1807, revives the ingenious explanation of Marriotte, and ſupports it with pertinent obſervations. He ſays, "it is well known that the cryſtals of ice and ſnow tend always to form angles of 60°; now, a priſm of water or ice, of 60°, produces a deviation of about 23½° for rays forming equal angles with its ſurfaces, and the angle of deviation varies at firſt very ſlowly as the inclination changes, the variation amounting to leſs than 3°, while the inclination changes 30°. Now, if ſuch priſms were placed at all poſſible angles of inclination, differing equally from each other, one half of them would be ſo ſituated, as to be incapable of tranſmitting any light regularly by two ſucceſſive refractions, directed the ſame way; and of the remaining two-fourths, the one would refract all the light within theſe three degrees, and the other would diſperſe the light in a ſpace of between 20° and 30° beyond them. In the ſame manner we may imagine an immenſe number of priſmatic particles of ſnow to be diſpoſed in all poſſible directions, and a conſiderable proportion of them to be ſo ſituated, that the plane of their tranverſe ſection may paſs within certain limits of the ſun and the ſpectator. Then half of theſe only will appear illuminated, and the greater part of the light will be tranſmitted by ſuch as are ſituated at an angular diſtance of 23½°, or within 3° of it; the limit being ſtrongly marked internally, but the light being externally more gradually loſt. And this is preciſely the appearance of the moſt common halo. When there is a ſufficient quantity of the priſmatic particles, a conſiderable part of the light muſt fall, after one refraction, on a ſecond particle, ſo that the effect will be doubled; and in this caſe the angle of refraction will become ſufficient to preſent a faint appearance of colour, the red being internal, as the leaſt refrangible light, and the external part having a tinge of blue. Theſe concentric halos of 23½° and 47°, are, therefore, ſufficiently explicable, by particles of ſnow, ſituated promiſcuouſly in all poſſible directions. If the priſms be ſo ſhort as to form triangular plates, theſe plates, in falling through the air, will tend to aſſume a vertical direction, and a much greater number of them will be in this ſituation than in any other. The reflection from their flat ſurfaces will conſequently produce a horizontal circle of equal height with the ſun; and their refraction will exhibit a bright parhelion immediately over the ſun, with an appearance of wings or horns, diverging upwards from the parhelion."

Whatever may be the facility of explaining the phenomena of halos, parhelia, and paraſelenes by the aſſumption of triangular priſmatic particles of ice and thin plates of the ſame, it is upon the whole perhaps equally probable, that theſe phenomena are moſt, if not all, occaſioned by the refraction and reflection of light from the ordinary minute globules of water in the atmoſphere, before they become aggregated ſo as to form a cloud. Thus the flame of a candle ſeen through ſteam in cold weather, or through glaſs that has been breathed upon, or through a receiver during its exhauſtion, or after the re-admiſſion of air, exhibits the appearance of a halo. Alſo water thrown up againſt the ſun, and diſperſed in ſmall drops, ſhews the colours of the rainbow. It has been obſerved, that large halos do not appear concentric to the ſun or moon, but farther extended downwards than upwards; this, as Dr. Smith ſhews, is an optical deception, ariſing from the apparent concave of the ſky being leſs than a hemiſphere.

The *anthelia* or *glories* ſeen around the ſhadows of perſons' heads in certain ſituations, appear to have a ſimilar origin to the rainbows, or perhaps to the larger halos. The moſt accurate deſcription of theſe is given by Bouguer; they were obſerved by him and his companions on Pichinca, a high mountain in South America. When the ſun was juſt riſing behind them, and a cloud was about thirty paces before them, ſo as to appear white, each of them ſaw his own ſhadow projected upon it, and no other. All the parts of the ſhadow were diſtinguiſhable, but the head was adorned with a kind of glory, conſiſting of three or four ſmall concentric crowns of a very lively colour, each exhibiting all the varieties of the primary rainbow, and having the circle of red on the outſide. The intervals between theſe circles continued equal, though the diameters of them all were conſtantly changing. The laſt of them was very faint, and at a

conſiderable

conſiderable diſtance was another great white circle which ſurrounded the whole. The diameter of the firſt circle was eſtimated at 5 $\frac{2}{3}$, that of the ſecond at 11°, and that of the third at 17°; but the diameter of the white circle was about 67°. This phenomenon never appeared but in a cloud, conſiſting of frozen particles, and never in drops of rain, like the rainbow. When the ſun was not in the horizon, only part of the white circle was viſible, as Bouguer frequently obſerved afterwards. An appearance, ſomewhat ſimilar, was obſerved by Dr. M'Fait in Scotland; alſo by Dr. Haygarth in Wales in 1780. The fog or miſt in the laſt caſe too was probably frozen, as hoar froſt was obſerved the ſame evening.

Though the above accounts ſeem to ſhew that theſe glories are not produced but in fogs below the freezing temperature; yet it would be too haſty to adopt this concluſion till it ſhall be corroborated by the obſervations of other perſons, placed in ſimilar ſituations in more elevated temperatures.

For further accounts ſee ANTHELION, PARHELION, and the works above mentioned, Nicholſon's Journal, vol. vi. and Prieſtley's Hiſtory of diſcoveries relating to Viſion, &c.

HALO, in *Anatomy*, the name given by authors to that round red circle, or areola, about the nipple, from its ſimilitude to the circles formed round the ſun and moon at certain times, and called *halos*.

HALONNESUS, in *Ancient Geography*, a ſmall iſland in the Ægean ſea, which became the occaſion of a war between Philip, king of Macedonia, and the Athenians.

HALORAGIS, in *Botany*, from ἁλς, *the ſea*, and ῥαξ, *a grape ſtone*, becauſe its fruit reſembles ſuch, and the plant grows by the ſea ſide. Forſt. Gen. 31. t. 31. Linn. Suppl. 34. Schreb. 267. Willd. Sp. Pl. v. 2. 473. Jacq. Miſc. v. 2. 332. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 37. (Cercodia; Murr. Comm. Goett. for 1780. 3. Juſſ. 318. 451. Lamarck. Illuſtr. t. 319. Gærtn. t. 32.)—Claſs and order, *Octandria Tetragynia*. Nat. Ord. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, deeply four-cleft, crowning the germen, permanent. *Cor.* Petals four, oblong, obtuſe, concave, more or leſs ſpreading; their claws narrow, inſerted into the calyx. *Stam.* Filaments eight, capillary, erect, ſhorter than the corolla, inſerted into the calyx; anthers oblong, with four furrows, erect. *Piſt.* Germen inferior; ſtyles four, upright; ſtigmas ſimple, obtuſe. *Peric.* Drupa dry, roundiſh, crowned with the permanent calyx. *Seed.* Nut hard, of four cells, with a kernel in each.

Eſſ. Ch. Calyx deeply four-cleft, ſuperior. Petals four. Drupa dry. Nut of four cells.

1. H. *Cercodia*. (H. alata; Jacq. Ic. Rar. t. 69. Forſt. Prod. 30. Cercodia erecta; Murr. Comm. Goett. for 1780. 3. t. 1. Tetragonia ivæfolia; Linn. Suppl. 257.)—Leaves ovate, ſerrated. Flowers whorled.—Found in New Zealand by ſir Joſeph Banks, who introduced it to the Kew garden in 1772, where it is kept in the greenhouſe, flowering moſt part of the ſummer. The *ſtem* is ſhrubby, branched, erect, about two feet high, ſquare, with rough angles, reddiſh. *Leaves* oppoſite, ſtalked, ſpreading horizontally, about an inch long, ovate, acute, various in breadth, unequally and ſharply ſerrated, light green, roughiſh to the touch, but not hairy. *Stipulas* none. *Flowers* about ſix in a whorl, ſmall, green with a red tinge, pendulous, on ſhort rough reflexed ſtalks. *Fruit* ſmall, ovate, quadrangular. The ſpecific name of *erecta* ought to have been retained for this ſpecies, but we follow Aiton and Willdenow, who followed Medicus.

2. H. *proſtrata*. Forſt. Prod. 30 Linn. Suppl. 229.—Leaves obovate, entire. Flowers axillary, ſolitary. Stem decumbent.—Gathered by Forſter in New Caledonia. His own ſpecimen of this, like many other plants, was given to Linnæus by Bæck. The *ſtem* is procumbent, with ſquare, ſmooth, leafy branches. *Leaves* crowded, oppoſite, on ſhort ſtalks, oblong or obovate, ſcarcely an inch in length, pointed, entire, ſomewhat revolute, ſmooth. *Flowers* ſolitary, on ſhort ſtalks, from the boſoms of the upper leaves. *Fruit* ſmall, globoſe, reddiſh.

3. H. *racemoſa*. Billard. Nov. Holl. v. 1. 100. t. 128.—Leaves lanceolate, ſerrated. Flowers in terminal and axillary cluſters.—Native of Lewin's land, on the ſouth coaſt of New Holland, where it was gathered by La Billardiere. *Stem* ſhrubby, ſquare, branched, ſmooth, a foot and half high. *Leaves* an inch and half or two inches long, ſlightly ſtalked, lanceolate, narrow, bluntiſh, with ſhallow ſerratures. *Cluſters* of ſeveral flowers, naked, an inch or more in length, terminal and axillary about the tops of the branches. *Flowers* ſmall, erect. *Fruit* pendulous, quadrangular, properly with four cells, but by abortion often having one only. The *petals* are ſometimes wanting.

4. H. *digyna*. Billard. Nov. Holl. v. 1. 101. t. 129.—Leaves ſcattered, linear, entire. Cluſters leafy, terminal.—From the ſame country as the laſt, with which it agrees in general habit, and from analogy with which the *flowers* are to be deemed racemoſe, as they grow about the extremities of each branch, in great numbers, and about half of them, in the lower part only, are accompanied by leaves. They are ſmall and pendulous, on ſhort ſtalks. The *leaves* are alternate, or ſcattered, the length of the laſt, but very narrow, rather fleſhy, blunt and entire. *Styles* but two. *Fruit* globoſe, without angles.

HALOSACHNE, formed of ἁλς, *ſea*, and αχνη, *froth*, in the *Materia Medica of the Ancients*, was a name given to a peculiar ſea-ſalt, made by the evaporation of ſmall quantities of ſea-water on rocks, by the ſun's heat. It no way differed from the common ſea-ſalt in its qualities or properties, except that it did not crackle ſo much in the fire; and this was merely owing to its being compoſed of finer particles, and in form of a ſort of powder, in which ſtate even common ſea-ſalt will no more crepitate in the fire than this. Hill's Hiſt. of Foſſ. p. 386.

Though this, however, was the common appearance of the haloſachne, it was not its univerſal one; for it was found ſometimes concreted on, or embodied in the alcyonia and other marine productions, and then appeared in a harder form.

HALOSANTHOS, of ἁλς, *ſea*, and ανθος, *flower*, *flower of ſalt*, was a ſubſtance though commonly ſuppoſed only an effloreſcence of common ſalt, yet really a bituminous matter mixed with ſome particles of ſalt.

It was a tough, viſcous, and fatty ſubſtance, found ſwimming on the waters of ſome ſprings and rivers, and was of a ſoft conſiſtence and of a yellow colour: and the ſame ſubſtance is ſtill found in the ſame places, and that not only yellow, but of various other colours, as blackiſh, green, or blue; theſe it takes up, according to the various earths it has waſhed againſt on the ſhores, or the ſubſtances mixed among it at its original concretion. The deſcription Dioſcorides gives of it is very expreſs; he ſays it was found ſwimming on the waters of the Nile, and ſome lakes, and was of a yellowiſh colour, very ſharp to the taſte, fattiſh, and of an unpleaſant ſmell. This, though that author did not diſtinguiſh to what claſs of foſſils it properly belonged, is enough, however, to teach us what it truly was; and it is ſomething wonderful, that thoſe who have accounted it a ſalt, ſhould not obſerve that the ſame author adds, that it was ſoluble in oil and not in water. Hill's Hiſt. Foſſ. p. 386.

HALS,

HALS, Francis, in *Biography*, a portrait painter of great celebrity, born at Mechlin in 1584. He was a pupil of C. Van Mander, and ſtudying nature at the ſame time, he obtained great knowledge of the ſtructure of the human frame, as far as he required it in his practice. No man ever ſet the features of a face together with more truth than Frank Hals; or with a readier pencil; and he did it with great truth and ſpirit alſo of colour, as well as of execution. He avoided the laboured mode of finiſh, ſo much admired among his countrymen at the time, and gave his portraits much expreſſion and animation of countenance, particularly of a gay and humorous nature. He was famed for the ſtrong reſemblances his pictures conveyed of their originals.

Vandyke was ſo delighted with his works, that he thought him worthy of attention, and went to Haerlem, where he reſided, for no other purpoſe than to pay him a viſit. He introduced himſelf as a gentleman on his travels, who wiſhed in haſte to have his portrait painted. Hals was hurried from the tavern where he uſually paſſed his leiſure time, ſeized the firſt canvas he could find, and began his labour.

In a ſhort time he had proceeded ſo far, that he aſked Vandyke to look at what he had done, who expreſſed himſelf as very well pleaſed with it, at the ſame time ſaying that he thought ſuch work ſo eaſy, he was perſuaded he could do it himſelf. Taking the palette and pencils he deſired F. Hals to ſit down, and in a quarter of an hour ſhewed him the portrait. The moment he ſaw it he recognized his viſitor, and embraced him with tranſport.

Vandyke endeavoured to prevail upon Hals to accompany him to England, engaging to enrich him; but he was not able to ſucceed; Hals declaring that his happineſs conſiſted in the enjoyment of his friends and his bottle, and while he poſſeſſed theſe he was ſatisfied with his condition.

The talents of Hals would have raiſed him into ſtill more eſteem, if he had known how to give elegance or poliſh to his characters. But his idol was truth, and his repreſentation of it rather too ſevere. He died in 1666, at the age of 82.

Hals, Dirk, a painter of animals, merry-makings, converſations, feaſts, and ſubjects of drollery. He was brother of Frank Hals, to whom however as an artiſt he was far inferior in all the better qualities of art: ſtill his works gained him much reputation, and he practiſed with great ſucceſs till he was 67 years old, when he died in 1656.

Hals, in *Geography*, a town of Bavaria, with a county ſituated on the Iz; 2 miles N. of Paſſau.

HALSFANG. See Healfang and Pillory.

HALSINGLAND, in *Geography*. See Helsingland.

HALSTEAD is a large and populous town in the hundred of Hinkford and county of Eſſex, England, ſituated on the acclivity of a gravelly eminence near the river Colne, and deriving its name from two Saxon words, ſignifying *healthy place*. In Edward the Confeſſor's time it was held by earl Godwin and divers ſokemen and freemen; but it appears to have been divided, on the Conqueſt, among the Norman chiefs, Richard Fitz-Gilbert, earl of Brion; William de Warren, earl of Warren, and afterwards earl of Surrey; and Robert Malet, who had alſo the barony of Aye in Suffolk. The market here was probably eſtabliſhed in the Saxon times, as a hill at the upper end of the town, on which it was held for ſeveral centuries after the Conqueſt, has the name of Cheping Hill. Till the year 1251 it appears to have belonged to the crown; but about that time Henry III. granted it to Abel de St. Martin, who held two knight's fees in Halſtead and Belchamp, of Richard de Clare, earl of Glouceſter and Hertford, who inherited this manor from Richard Fitz-Gilbert. Hugh de Vere, fourth earl of Oxford, indicted Abel de St. Martin for ſetting up a market at Halſtead to his prejudice, as being too near to his own markets at Caſtle Hedingham, and Earl's Colne; but the difference was adjuſted on Abel's conſenting to pay half a mark yearly to the earl, and proving his right to a market at Halſtead, both by preſcription and the king's grant. About this period it appears to have been ſomewhere on the king's highway; but it was now removed to its ancient ſtation on Cheping Hill, where it continued till the reign of Elizabeth, when it was again removed, and fixed in its preſent ſituation, near the centre of the town. The church, dedicated to St. Andrew, is an old building, conſiſting of a nave, chancel, and ſide aiſles, with a tower and ſpire at the weſt end. The ſpire is of wood, and is the third that has been erected on the preſent tower, the two former having been deſtroyed by lightning. The ſecond ſpire was raiſed, in 1717, at the expence of Mr. Samuel Fiſke, an apothecary of this town. A chantry was founded in this church for a maſter and five prieſts, by Bartholomew, lord Bourchier, under a licence obtained from Edward III. in 1340, by Robert Bourchier, earl of Eſſex and lord chancellor of England, who was buried here, and whoſe monument is ſuppoſed to be in the ſouth aiſle, together with another ancient tomb of the Bourchiers, on which are the effigies of a knight croſs-legged, and his lady. The college for the chantry prieſts is yet ſtanding near the middle of the town. Among the charitable benefactions to this town, is a grammar-ſchool, founded in 1594 by dame Mary Ramſey, for 40 poor children; the direction of which ſhe veſted in the governors of Chriſt's Hoſpital, London. Halſtead is 46 miles diſtant from London, has a market on Friday, and two annual fairs. In the year 1801 the number of houſes was 784, of inhabitants 3380, of whom 1654 were returned as employed in trades and manufactures, principally that of baize and ſays, for which this town was formerly much noted. Morant's Hiſtory of Eſſex, two vols. folio.

HALT, in *War*, a pauſe or ſtop in the march of a military body.

Some derive the word from the Latin *halitus*, *breath*, it being a frequent occaſion of halting, to take breath; others from *alto*, becauſe in halts they raiſe their pikes, &c. on end.

Halt, in *Rural Economy*, a ſort of limping or lameneſs that affects different ſorts of animals, and which proceeds from many different cauſes. It ſhould always be carefully attended to on its firſt appearance.

Halt *Foot*, the name of a troubleſome diſeaſe in the feet of ſheep. It has been ſuppoſed to ariſe from different cauſes, but moſt commonly from a vermicular kind of inſect of conſiderable length. Its preſence is indicated by a ſort of limping or lameneſs in the animal, and its being prevented from feeding in a proper manner; alſo, by the ſheep becoming weak and languid, with conſiderable emaciation, in conſequence of the want of ſufficient food, and the exquiſite pain which it ſuffers. This is particularly the caſe when the cauſe of the diſeaſe is not expeditiouſly removed.

Upon the lameneſs being firſt perceived the foot ſhould be very carefully examined, eſpecially in the diviſion between the claws, where an opening is frequently met with, through which it is ſuppoſed the inſect has paſſed, in an upward direction, betwixt the bone and the integuments, or covering. With the intention of removing it, the claws ſhould be wrought gently backwards and forwards, until the inſect is brought out on the ſurface, which is ſuppoſed by ſome a much better practice than that of drawing it out, on account of the danger there is of breaking it in the operation, and the injury

injury that may thereby be done to the foot of the animal. It is likewiſe conceived that very great benefit may be derived from the changing of the ſheep into ſuch paſtures as are dry and firm, both in the prevention and removal of the diſorder, as it is moſtly found to prevail in the damp, moiſt, autumnal, and early ſpring ſeaſons, and where the ſituations are low, moiſt, and marſhy. It however often occurs in other places.

HALTER, in *Rural Economy*, the name of an apparatus of the rope kind, formed for the purpoſe of putting upon the heads of horſes and other animals, in the view of leading or confining them. The head-part is ſometimes formed of rope, but at others of a ſort of narrow hempen web or girth, to which the rope-part is faſtened.

The term is alſo applied to a head-ſtall formed of leather, which is mounted ſometimes with one, and at others two ſtraps, having a ſecond throat-band where the horſe is liable to unhalter himſelf. In this caſe, a long ſtrap of leather is fixed to the head-ſtall in order to ſecure the horſe to the manger by, though ſometimes rope is employed for the purpoſe.

The improved ropes, formed from coarſe wool, are excellent for this uſe, as being both neat and durable, while they ſlide more readily in the rings of the mangers.

HALTER *Caſt*, an accident ſometimes occurring to horſes conſequence of the halters being left too long in tying them to the blocks. An excoriation of the paſtern is frequently produced by this means, which is very troubleſome in its removal. In the intention of preventing accidents of this nature, a ſpring-ſtaple has been contrived for the halter-ring to hang in, and deſcribed in the Tranſactions of the Society of Arts, and which is ſhewn in the annexed plate at *fig.* 1.: *a* is the ſpring paſſing through a mortice in the ſharp of the ſtaple cloſe to the part that is ſcrewed into the manger rail, which, preſſing againſt the lever *b*, keeps it ſhort. By this means the horſe, in pulling downwards, on becoming entangled, overcomes the power of the ſpring, and is thereby enabled to ſet himſelf at liberty.

It is neceſſary that all ſuch horſes, as have the habit of unhaltering themſelves, ſhould have throat-bands to their halters.

For the cure of this, anoint and waſh the place, morning and evening, with equal quantities of linſeed oil and brandy, or vinegar and brandy, well mixed: or, waſh the injured part with lead-water, or weak alum water. If it be much inflamed, apply a poultice, made of turnips boiled till they are tender, and after ſqueezing out the water, let them be chopped with two or three ounces of hog's lard: put this into a cloth and tie the foot in it, and let it remain all night. Accidents of this kind may be often prevented by faſtening a block of wood at the end of the halter.

HALTER-*ſtrap* or *ſtring*, a cord or long ſtrap of leather, made faſt to the head-ſtall and to the manger, to tye the horſe.

HALTEREN, in *Geography*, a town of Germany, in the biſhopric of Munſter, ſituated on the Lippe; 20 miles S.W. of Munſter. N. lat. 51° 45'. E. long. 7° 17'.

HALTERISTÆ, in *Antiquity*, a ſort of players at diſcus, ſo denominated from a peculiar kind of diſcus, by the Greeks called ἅλτηρ, and by the Latins *halter*.

Budæus, and others, take the halter to have been a leaden weight or ball, which the vaulters bore in their hands, to ſecure and keep themſelves more ſteady in their leaping. Nor will theſe authors allow of any ſort of halter beſides this weight; nor other halteriſts but theſe vaulters. Others, as Cornarius, Conſtantine, and Portus, will have the halter to be a lump or maſs of lead or ſtone, with an hold or handle fixed to it, by which it might be carried; and that the halteriſtæ were thoſe who exerciſed themſelves in removing thoſe weights from place to place. Theſe authors add, that the weight or ball mentioned by Budæus, was not called ἅλτηρ, *halter*, but ἀλκτὴρ, *alter*, which ſignifies *helper*, *defender*.

Hier. Mercurialis, in his treatiſe De Arte Gymnaſtica, lib. ii. cap. 12. diſtinguiſhed two kinds of halteriſtæ; for though there was but one halter, there were two ways of applying it. The one was to throw or pitch it in a certain manner; the other only to hold it out at arm's end; and in this poſture to give themſelves divers motions, ſwinging the hands backwards and forwards, &c. according to the engraven figures thereof given us by Mercurialis.

The halter was of a cylindrical figure, ſmaller in the middle (where it was held) by one diameter, than at the two ends. It was about a foot long, and there was one for each hand. It was made either of iron, ſtone, or lead. Galen, de Tuend. Valetud. lib. i. lib. v. and lib. vi. ſpeaks of this exerciſe, and ſhews of what uſe it is in purging the body of peccant humours; making it equivalent both to purgation and phlebotomy.

HALTING, among *Farriers*, &c. an irregularity in the motion of a horſe, ariſing from a lameneſs or other injury in the ſhoulder, leg, or foot; which leads him to ſpare the part, or uſe it too timorouſly.

An acquaintance with this diſorder, in its ſeveral circumſtances, is a thing of great extent in the affairs of the manege; for which reaſon we ſhall add the principal points relating to it. If a horſe halts, it is either *before*, in which caſe his complaint lies either in the ſhoulder, the legs, or feet; or *behind*, where it muſt lie in the hip, ham, or the like.

1. The ſigns which indicate it in the ſhoulder, are his not lifting up his leg, but trailing it on the ground, or his caſting one leg more than the other, and with his knee, in a manner, unbent; and, that in turning ſhort he will viſibly favour the leg on the lame ſide. Again, if the ailment be found on the ſhoulder, it muſt either be in the top of the ſhoulder-blade, called the *withers*, which is known by his halting moſt when a perſon is on his back, his ſhrinking much, and offering to bite when griped and handled about the top of the ſhoulder-blade, or in the bottom of the ſhoulder-blade, joining to the marrow-bone, which is the fore-pitch of the breaſt, and is known by his treading his ſteps thick, and ſhrinking, ready to fall down, when preſſed in that part; or in the elbow, which joins the marrow-bone to the leg, which is known by wincing and taking up his foot when pinched there.

2. If the grievance be in the *legs*, it either lies in the knee or paſtern joint, which he diſcovers by refuſing to bow the one or the other, and going ſtiffly on it; or in the *ſhank*, which is diſcovered by ſome ſplint, ſcrew, windgall, or other viſible malady thereon.

3. If it be in the *foot*, it is either in the coronet, and owing to ſome ſtrain, or to be diſtinguiſhed by ſome tumour or breaking thereon, or its appearing hot and burning to the touch; or in the *heel*, owing to an over-reach, or the like, and viſible to the eye; as alſo by his treading altogether on his toe; or in the *quarters*, between the middle of the hoof and the heel, which is known by his halting more when on the edge of a bank than when on plain ground. This is ſometimes occaſioned by being pricked with a nail in the ſhoeing; and the faulty nail is diſtinguiſhed by pinching the head of each nail, and the hoof together, with a pair of pincers.

If a horſe halt *behind*, from a diſorder in the hip or huckle-bone, he will go ſide-long, and not follow ſo well with that leg as the other; nor will he turn on that ſide without

without favouring the leg: add, that he ſhews it more in walking on the ſide of a bank with the worſt leg higheſt.

If a horſe has any hidden infirmity, that will bring him to halt when he comes to travel well, it may be diſcovered by running him in hand on a ſmooth way, at the length of the halter, and obſerving how he ſets down his legs: if he favour none of them, he is to be farther proved, by riding him roundly till heated; then letting him ſtand ſtill an hour, and after that running him in the hand at halter's length as before.

HALTON, in *Geography*, a townſhip and chapelry in the parith of Runcorn, and hundred of Bucklow, in the county palatine of Cheſter, was formerly a place of note, and contained a large baronial fortreſs with its uſual appendages. The barony of Halton was given by Hugh Lupus, earl of Cheſter, to his couſin Nigil, who was alſo conſtituted the earl's marſhal. During the protectorate of Cromwell, "the honor, fee, manor, and caſtle of Halton," were diſpoſed of by ſale, but reverted to the crown at the reſtoration. They are now leaſed from the crown to the earl of Cholmondeley. The barons of Halton poſſeſſed very extenſive privileges by grants from the earls of Cheſter: being conſtables of Cheſter, and marſhals; having the ward of the ſtreets of Cheſter during fair time; the liberty of having a caſtle and priſon at Halton; which town was alſo a free borough, with privilege of a weekly market and two fairs; to hold a court for the cognizance of various offences, to have a maſter ſerjeant and eight under ſerjeants, within the ſee of Halton; to have the advowries of all ſuch as ſhould put themſelves under their protection; to hold the town of Congleton as a free borough; with ſeveral other inferior privileges. A caſtle was built here ſoon after the Norman conqueſt; it was in ruins in Cromwell's time, but in a ſurvey then made a gate-houſe is deſcribed with five rooms over it; alſo one great hall with two ranges of buildings over it, containing nine rooms and a priſon. The honor of Halton is ſtated to have had juriſdiction over 37 townſhips in this county, and others in Lancaſhire. In this townſhip is Hallwood, the ſeat of ſir Richard Brooke, bart. whoſe father purchaſed it of Robert Newton, eſq. in 1799. This townſhip contained, in the year 1801, 137 houſes and 628 inhabitants. Lyſons's Magna Britannia, vol. ii. 4to. 1810.

HALTWHISTLE, a market town and pariſh in the weſt diviſion of Tynedale-ward, and near the S.W. corner of the county of Northumberland, England, is ſeated on the northern bank of the river Tyne. At a ſhort diſtance north of the town is part of Hadrian's wall, and to the weſt are traces of a Roman road, called the Maiden-way. Several Roman works are found in this part of the county: eaſt of the church is an encampment called Caſtle-banks: about three miles north of the town is Thelwall-caſtle; and another place is called Wall-town. Haltwhiſtle contained 104 houſes in the year 1801, and 453 inhabitants. It has a ſmall weekly market on Tueſdays, and two annual fairs.

HALVAN, or CHAULAN, a town of Africa, in Fez, celebrated for its baths; 10 miles S. of Fez.

HALY-ABBAS, in *Biography*, an Arabian phyſician and philoſopher, who flouriſhed in the latter part of the 10th century, and was held in ſuch high eſtimation on account of his learning, that he obtained the title of *Magus*. About the year 980 he wrote a book, which contains the fulleſt and beſt account, that has been tranſmitted to us, of the ancient Arabian phyſic, and which he intended as a complete ſyſtem of the art, and to ſupply the defects of preceding writers: for he affirmed, that no author had yet appeared, whoſe works were altogether complete; and he ſpecified ſeveral inſtances of failure in thoſe of Hippocrates, Galen, Oribaſius, and Paulus. This treatiſe of Haly-Abbas was entitled "Almaleci," or "The Royal Work," and was dedicated, in very hyperbolical language, according to the cuſtom of the eaſtern nations, to the caliph Adad-Odaula. It was tranſlated into Latin by Stephen of Antioch in 1127, and was ſtill in great eſtimation in the fifteenth century, when it was printed under the following title; "Regalis Diſpoſitionis Theoricæ Libri decem, et Practicæ Libri decem," Venetiis, 1492, in folio; and afterwards at Lyons in 1515, in folio, and in 1523, 4to. See Freind Hiſt. of Phyſ. Eloy. Dict. Hiſt.

HALYMOTE, properly ſignifies a holy or eccleſiaſtical court. See HALMOTE.

There is a court held in London by this name, before the lord mayor and ſheriffs, for regulating the bakers. It was anciently held on the Sunday next before St. Thomas's day, and for this reaſon called the halymote, or holy court. The title thereof runs thus: "Curia ſancti motus tenta in Guilhalda civitatis Londin. coram major & vicecom. &c."

HALYWERCFOLK anciently ſignified ſuch perſons of the province of Durham as held lands on condition of defending the corpſe of St. Cuthbert; and who hereupon claimed the privilege, not to be forced to go out of the biſhopric either by king or biſhop.

HAM, a Saxon word properly ſignifying a *houſe* or *dwelling-place*.

HAM is alſo uſed to denote a ſtreet or village.

Hence it is that the names of many of our towns end with it; as Notting*ham*, Bucking*ham*, Walſing*ham*, &c.

HAM is alſo a part of the leg of an animal; being the inner or hind part of the knee, or the ply or angle in which the leg and thigh, when bent, incline to each other.
